To get a feel for the new approach the **Policy & Objects > Policy > IPv4** window is a noticeable place to see some of these changes in action.

The different view modes are still in the upper right-hand corner as they were before but now there is no column settings link to move or configure the columns of the window. Now if you wish to reposition a column just use the mouse to click on the column heading and drag it to its new position. If you wish to add a new column just right-click on one of the column headings and a drop down menu will appear with the option “Column Settings”. Use the right pointing triangle to expand the “Column Settings” option to see a choice of possible columns for the window you are in. Those already selected will be at the top with a checked box and the available new ones will be at the bottom ready to be selected.

Rather than having a link to initiate a move in the positioning of policies in the sequence, you can select a policy and hold down the mouse button and drag it to its new position.

By right or secondary clicking the mouse curser in the cells of the Policy window you will get a drop down menu that is contextual to the column and policy row where you made the clck.For example if you right click in the “Schedule” column for the row that is for policy #5 you will get the option to select a schedule for policy #5 along with a number of other configuration options relating to that policy or its position in the sequence of policies.

You will find this approach used much more frequently through out the Web-based Manager, giving it a more modern and intuitive feel once you learn to use the right mouse button rather than finding a link displayed on the page.

Changing the default column setting on the policy page

The **Policy & Objects > Policy > IPv4** window is one of the more important ones in the Web based interface and has the capacity to display a lot of information, but displaying all of that information at the same time makes for a very busy screen. If all of the columns are displayed, depending on the screen size you may have to constantly use the scroll bars to see what you need to look at. The default installation shows some of the more commonly used columns but these list may not consist of the columns that you wish to look at or the order that you wish to view them in. For this reason it is possible, through the CLI to override these settings to establish a new default.

The syntax of the command starts with:

```
config system settings
   set gui-default-policy-columns
```

The rest of the command is a space delimited list that depends on the columns you wish to view and the order you wish to view them in. The possible selection is in the following table.

Variables for the gui-default-policy-columns command

Variable Name	Column Heading
#	Sequence Number
policyid	Policy ID
srcintf	Source Interface
dstintf	Destination Interface
srcaddr	Source Addresses
dstaddr	Destination Addresses
schedule	Policy Schedule
service	Policy Services
action	Policy Action
logtraffic	Traffic Logging Status
nat	Policy NAT Status
status	Policy Status
authentication	Authentication Groups
count	Policy Traffic Counter
profile	Security Profiles
vpntunnel	VPN Tunnel
comments	Policy Comment

Example

If you wanted these columns in this order, Policy ID, Source Addresses, Destination Addresses, Security Profiles, Policy Comment. You would enter the command:

```
config system settings
   set gui-default-policy-columns policyid srcaddr dstaddr profile comments
```

Naming rules and restrictions

The following are the specific rules that are obeyed by the FortiGate.

Duplicate Name Issues:

- A VLAN cannot have the same name as a physical interface.
- An Address must not have the same name as an Address Group.
- An Address or Address Group must not have the same name as a Virtual IP Address.
- A Service cannot have the same name as a Service Group.
- A VLAN must not have the same name as a VDOM.
- A VLAN or VDOM must not have the same name as a Zone.

Try to make each firewall object name as unique as possible so that it cannot be confused with another object.

Character restrictions

Object names cannot contain the following characters:

- <
- >
- (
-)

All other characters, including other languages, are supported as usable characters.

> FortiOS allows spaces in just about all object name fields, but this was not always the case. Some people are still cautious where this is concerned. If you're cautious about characters in the names of objects use this basic rule of thumb:
>
> When naming objects, only use characters that are alphanumeric (a-z, A-Z, 0-9) and where there is the temptation to use spaces in a name, use the '-' (dash) and '_' (underscore).

Numeric values

Numeric values are used to configure various sizes, rates, numeric addresses, or other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or as in the case of MAC or IPv6 addresses separated by colons (for example, the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again such as MAC addresses) require hexadecimal numbers.

Most web-based manager numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the web-based manager and the CLI prevent you from entering invalid numbers.

Numeric values

Numeric values are used to configure various sizes, rates, numeric addresses, or other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or as in the case of MAC or IPv6 addresses separated by colons (for example, the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again such as MAC addresses) require hexadecimal numbers.

Most web-based manager numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the web-based manager and the CLI prevent you from entering invalid numbers.

Selecting options from a list

If a configuration field can only contain one of a number of selected options, the web-based manager and CLI present you a list of acceptable options and you can select one from the list. No other input is allowed. From the CLI you must spell the selection name correctly.

Enabling or disabling options

If a configuration field can only be on or off (enabled or disabled) the web-based manager presents a check box or other control that can only be enabled or disabled. From the CLI you can set the option to enable or disable.

To enable or disable optionally displayed features

There are a number of features in the web-based manager that can be configured to either be displayed if you are likely to use them or disabled if you have no need to see them. The ones that may be relevant to the function of the Firewall are:

- Central NAT Table
- Dynamic Profile
- Explicit Proxy
- Implicit Firewall Policies
- IPv6
- Load Balance
- Local In Policy

You can enable or disable these features by going to **System > Admin > Settings** or by using the following CLI options:

```
config system global
   set gui-ap-profile {disable | enable}
   set gui-central-nat-table {disable | enable}
   set gui-dns-database {disable | enable}
   set gui-dynamic-profile-display {disable | enable}
   set gui-icap {disable | enable}
   set gui-implicit-id-based-policy {disable | enable}
   set gui-implicit-policy {disable | enable}
   set gui-ipsec-manual-key {enable | disable}
   set gui-ipv6 {enable | disable}
   set gui-lines-per-page <gui_lines>
   set gui-load-balance {disable | enable}
   set gui-object-tags {disable | enable}
   set gui-policy-interface-pairs-view {enable | disable}
   set gui-voip-profile {disable | enable}
end
```

Building firewall objects and policies

The other chapters in the Firewall book have so far been concerned primarily with concepts and abstract ideas that are designed you help you understand what is going on with the firewall and what it can do. Now that we have a good grounding in the “what” it is time to get into the “how”.

This section will provide the instructions for the web-based manager (when available) and the CLI for adding and or editing FortiGate firewall objects and then how to put them together when building a policy to govern the traffic flowing through your network. To give some context, scenarios have been included. The instructions here are concerned with the creation of the objects. The inclusion of these objects into firewall policies is not shown in these instructions.

This chapter includes the instructions for building the following:

- IPv4 Firewall Addresses
- IPv6 Firewall Addresses
- FQDN address

- Changing the TTL of a FQDN address
- New Geography-based Address
- IPv4 Address Group
- IPv4 Address Group
- IPv6 Address Group
- Multicast Address
- Service Category
- TCP/UDP/SCTP Service
- ICMP Service
- ICMPv6 Service
- Service Group
- Virtual IP address
- IP Pool
- Central NAT Table
- Firewall Schedule - Recurring
- Firewall Schedule - One-time
- Schedule Group
- Proxy Option
- DoS Policy

Building firewall objects and policies

The other chapters in the Firewall book have so far been concerned primarily with concepts and abstract ideas that are designed you help you understand what is going on with the firewall and what it can do. Now that we have a good grounding in the “what” it is time to get into the “how”.

This section will provide the instructions for the web-based manager (when available) and the CLI for adding and or editing FortiGate firewall objects and then how to put them together when building a policy to govern the traffic flowing through your network. To give some context, scenarios have been included. The instructions here are concerned with the creation of the objects. The inclusion of these objects into firewall policies is not shown in these instructions.

This chapter includes the instructions for building the following:

- IPv4 Firewall Addresses
- IPv6 Firewall Addresses
- FQDN address
- Changing the TTL of a FQDN address
- New Geography-based Address
- IPv4 Address Group
- IPv4 Address Group
- IPv6 Address Group
- Multicast Address
- Service Category
- TCP/UDP/SCTP Service

- ICMP Service
- ICMPv6 Service
- Service Group
- Virtual IP address
- IP Pool
- Central NAT Table

- Firewall Schedule - One-time
- Schedule Group
- Proxy Option
- DoS Policy

Example: IPv4 firewall addresses

Scenario: Mail server

You need to create an IPv4 address for the Mail Server on Port1 of your internal network.

- These server is on the network off of port1.
- The IP address is 192.168.1.27
- The subnet mask is 255.255.255.0
- There should be a tag for this address being for a server

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information:

Category	Address
Name	Mail_Server
Type	Subnet / IP Range
Subnet / IP Range	192.168.1.27/255.255.255.0
Interface	port1
Visibility	<enabled>
Comments	<add any additional discription>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address
   edit Mail_Server
      set type ipmask
      set subnet 192.168.1.27 255.255.255.255
      set associated-interface port1
   end
```

Scenario: First floor network

You need to create an IPv4 address for the subnet of the internal network off of Port1.

- These computers are on the network off of port1.
- The subnet is the range from 192.168.1.1 to 192.168.1.255.
- The subnet mask is 255.255.255.0
- There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	Address
Name	Internal_Subnet_1
Type	Subnet
Subnet / IP Range	192.168.1.0/24
Interface	port1
visibility	<enabled>
Comments	Network for 1st Floor

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address
   edit Internal_Subnet_1
      Set comment "Network for 1st Floor"
      set type ipmask
      set subnet 192.168.1.0/24
      set associated-interface port1
   end
```

Scenario: Marketing department

You need to create an IPv4 address for the address range for a group of computers used by the Marketing Department.

- These computers are on the network off of port1.
- The IP addresses for these computers range from 192.168.1.100 to 192.168.1.115

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	Address
Name	Marketing_computers
Type	IP Range

Subnet / IP Range	192.168.1.100-192.168.1.115
Interface	port1
Visibility	<enable>
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address
   edit Internal_Subnet_1
      set type iprange
      set start-ip 192.168.1.100
      set end-ip 192.168.1.115
      set associated-interface port1
   end
```

Verification

To verify that the addresses were added correctly:

1. Go to **Policy & Objects> Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address
   edit <the name of the address to verify>
   show full-configuration
```

Example: IPv6 firewall addresses

Scenario: Mail server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network.

- These server is on the network off of port1.
- The IP address is 2001:db8:0:2::20/64
- There should be a tag for this address being for a server

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	IPv6 Address
Name	Mail_Server
Type	Subnet
Subnet / IP Range	2001:db8:0:2::20/64
Interface	port1

Visibility	<enable>
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address6
   edit Mail_Server
      set type ipmask
      set subnet 2001:db8:0:2::20/64
      set associated-interface port1
   end
```

Scenario: First floor network

You need to create an IPv4 address for the subnet of the internal network off of Port1.

- These computers are on the network off of port1.
- The Network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx
- There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	IPv6 Address
Name	Internal_Subnet_1
Type	Subnet
Subnet / IP Range	2001:db8:0:2::/64
Interface	port1
Visibility	<enable>
Comments	Network for 1st Floor

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address6
   edit Internal_Subnet_1
      Set comment "Network for 1st Floor"
      set subnet 2001:db8:0:2::/64
   end
```

Verification

To verify that the addresses were added correctly:

1. Go to **Policy & Objects> Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address6
```

```
edit <the name of the address that you wish to verify>
   Show full-configuration
```

Example: FQDN address

You have to great a policy that will govern traffic that goes to a site that has a number of servers on the Internet. Depending on the traffic or the possibility that one of the servers is down network traffic can go to any one of those sites. The consistent factor is that they all use the same Fully Qualified Domain Name.

- The FQDN of the web site: example.com
- The number of ISP connections off of the FortiGate firewall: 2

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information:

Category	Address
Name	BigWebsite.com
Type	FQDN
FQDN	bigwebsite.com
Interface	any
Visibility	<enable>
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address
   edit BigWebsite.com
      set type fqdn
      set associated-interface any
      set fqdn bigwebsite.com
   end
```

Verification

To verify that the addresses were added correctly:

1. Go to **Firewall Objects > Address > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

Changing the TTL of a FQDN address

To make sure that the FQDN resolves to the most recent active server you have been asked to make sure that the FortiGate has not cached the address for any longer than 10 minutes.

There is no field for the cached time-to-live in the web-based manager. It is only configurable in the CLI. Enter the following commands:

```
config firewall address
   edit BigWebsite.com
      set cache-ttl 600
   end
```

Example: Geography-based address

Your company is US based and has information on its web site that may be considered information that is not allowed to be sent to embargoed countries. In an effort to help reduce the possibility of sensitive information going to those countries you have be asked to set up addresses for those countries so that they can be block in the firewall policies.

- One of the countries you have been asked to block is Cuba
- You have been asked to comment the addresses so that other administrators will know why they have been created

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	Address
Name	Cuba
Type	Geography
Country	Cuba
Interface	any
Visibility	<enable>
Comments	Embargoed

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address
   edit Cuba
      set type geography
      set country CN
      set interface wan1
   end
```

Example: IPv4 address group

Your company has a small division that is in Denmark that has a number of remote users that need to connect to a resource from either home, office or customer sites. The thing that they have in common is that there are all in Denmark. An address group needs to be created that will allow for this.

The preconfigured addresses to use will consist of:

- Denmark - a geography based address
- Denmark_ISP1 - a IP range of address of an ISP that services Denmark

- Denmark_ISP2 - a IP range of address of another ISP that services Denmark
- Denmark_Division - the FQDN of the Denmark office that uses Dynamic DNS

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address Group.**
2. Fill out the fields with the following information

Type	IPv4 Group
Group Name	Denmark_Users
Show in Address List	<enable>
Members	Denmark Denmark_ISP1 Denmark_ISP2 Denmark_Division
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall addrgrp
   edit Denmark_Users
      set member Denmark Denmark_ISP1 Denmark_ISP2 Denmark_Division
   end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects> Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall addgrp
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

Example: IPv6 address group

Create IPv6 address groups from existing IPv6 addresses

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

The preconfigured addresses to use will consist of:

- Web_Server-1
- Web_Server-2
- Web_Server-3

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address Group.**
2. Fill out the fields with the following information

Type	IPv6 Group
Group Name	Web_Server_Cluster
Show in Address List	<enable>
Members	Web_Server-1 Web_Server-2 Web_Server-3
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall addrgrp6
   edit Web_Server_Cluster
      set member Web_Server-1 Web_Server-2 Web_Server-3
   end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects> Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall addgrp6
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

Example: Multicast address

The company has a large high tech campus that has monitors in many of its meeting rooms. It is common practice for company wide notifications of importance to be done in a streaming video format with the CEO of the company addressing everyone at once.

The video is High Definition quality so takes up a lot of bandwidth. To minimize the impact on the network the network administrators have set things up to allow the use of multicasting to the monitors for these notifications. Now it has to be set up on the FortiGate firewall to allow the traffic.

- The range being used for the multicast is 239.5.0.0 to 239.5.255.255
- The interface on this FortiGate firewall will be on port 4

1. Go to **Policy & Objects> Objects > Addresses** and select **Create New > Address.**
2. Fill out the fields with the following information

Category	Multicast Address
Name	Meeting_Room_Displays
Type	Multicast IP Range

Multicast IP Range	239.5.0.0-239.5.255.255
Interface	port4
Visibility	<enable>
Comments	<Input into this field is optional>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall multicast-address
   edit "meeting_room_display"
      set associated-interface "port9"
      set start-ip 239.5.0.0
      set end-ip 239.5.255.255
      set visibility enable
      next
   end
```

To verify that the address range was added correctly:

1. Go to **Policy & Objects> Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall multicast-address
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

Example: Service category

Add a new category to the list of Service Categories

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of “Surveillance”

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Category.**
2. Fill out the fields with the following information

Name	Surveillance
Comments	For DataCenter Surveillance Devices

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service category
   Edit Surveillance
      Set comment “For DataCenter Surveillance Devices”
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services**. Select the Category Settings icon . A listing of the categories should be displayed.
2. Enter the following CLI command:

```
config firewall service category
  show
```

This should bring up all of the categories. Check to see that the new one is displayed.

Example: TCP/UDP/SCTP service

To create and configure a TCP/UDP/STCP protocol type service.

You have set up some new web cams at work that send a constant live feed to a security service. Not only do these cameras have a feed that can be sent offsite they can be remotely managed from a browser or an application.

The ports that need to be opened to use all of the features of the web cams are:

- Management by browser - TCP on port 8000
- Real time video feed - UDP on port 4000
- Connection through vendor application - SCTP on port 1600

The IP address of the offsite service is 256.25.56.12 (Not a valid IP address. Used for example only)

- One service will be needed for the incoming connections
- One service will be needed for the outgoing connections

The IT manager would like the service for the outgoing data stream to be tied to the destination of the Surveillance service site so that service can only be used for that one vendor.

To add the incoming service

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	WebCam_Connection-incoming
Comments	<Input into this field is optional>
Service Type	Firewall
Show in Service List	Check in check box
Category	Surveillance
Protocol Type	TCP/UDP/SCTP
IP/FQDN	<Leave blank>

	Destination Port		Source Port	
Protocol	Low	High	Low	High
TCP	8000	8000	1	65535
SCTP	16000	16000	1	65535

The source port range can be left blank as the default is 1 to 65635.

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
   edit WebCam_Connection-incoming
      Set protocol TCP/UDP/SCTP
      Set tcp-portrange 8000
      Set sctp-portrange 16000
      Set visibility enable
   end
```

To add the outgoing service

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	WebCam_Connection-outgoing
Comments	<Input into this field is optional>
Service Type	Firewall
Color	<Changing this value is optional>
Show in Service List	Check in check box
Category	Surveillance
Protocol Type	TCP/UDP/SCTP
IP/FQDN	256.25.56.12

	Destination Port		Source Port	
Protocol	Low	High	Low	High
TCP	4000	4000	1	65535

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
   edit WebCam_Connection-incoming
      Set protocol TCP/UDP/SCTP
      Set category Surveillance
      Set udp-portrange 4000
      Set iprange 256.25.56.12
      Set visibility enable
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services.** Check that the services have been added to the service list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
   edit <the name of the service that you wish to verify>
      Show full-configuration
```

This should bring up all of the details of the service.

Example: ICMP service

The Security Officer would like to block the use of the traceroute utility through the network. The IT manager insists that ping and other ICMP utility must be allows for the task of diagnosing connectivity, so it is agreed that only traceroute functionality will be blocked.

The ICMP type for traceroute is 30. There is no codes with the type.

Web-based Manager Instructions

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	traceroute
Comments	<Input into this field is optional>
Service Type	Firewall
Show in Service List	Check in check box
Category	Uncategorized
Protocol Type	ICMP
Type	30
Code	<Leave blank>

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
```

```
edit traceroute
   set protocol ICMP
   set icmptype 30
   set visibility enable
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services.** Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
   edit <the name of the service that you wish to verify>
      show full-configuration
```

Example: ICMPv6 service

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

Web-based Manager Instructions

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	diagnostic-test1
Comments	<Input into this field is optional>
Service Type	Firewall
Show in Service List	Check in check box
Category	Uncategorized
Protocol Type	ICMP6
Type	140
Code	0

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
   edit diagnostic-test1
      set protocol ICMP6
      set icmptype 140
      set icmpcode 0
      set visibility enable
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services.** Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
   edit <the name of the service that you wish to verify>
      show full-configuration
```

Example: Service group

The company provide email services for a number of different companies. They have a standard list of services that they like to keep open to their customer's email servers, including webmail services. The company prides itself on getting a customer up and going the same day so they use standard templates for everything to make sure nothing is forgotten including the services that are available. The services include:

- IMAP
- IMAPS
- POP3
- POP3S
- SMTP
- SMTPS
- HTTP
- HTTPS
- Email_Admin - a custom service for administration of the servers

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service Group**.
2. Fill out the fields with the following information:

Group Name	Cust_Email_Serv_Template
Comments	(Optional)
Type	Firewall
Members	(click to add…choose from the drop down) • IMAP • IMAPS • POP3 • POP3S • SMTP • SMTPS • HTTP • HTTPS • Email_Admin

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service group
   edit Cust_Email_Serv_Template
```

```
    set member "IMAP" "IMAPS" "POP3" "POP3S" "SMTP" "SMTPS" "HTTP" "HTTPS" "Email_
        Admin"
    next
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services.** Check that the service group has been added to the services list and that it is correct.
2. Enter the following CLI command:

```
config firewall service group
  edit <the name of the service that you wish to verify>
    show full-configuration
```

Example: Virtual IP address

The company has an web server on the internal network that needs to be accessed from the Internet.

- The internal IP address is 192.168.50.37
- The external IP address is 256.85.94.60 (for example use only. Not a valid IP address)
- The external IP address is assigned by ISP "A" on WAN1
- The port that needs to be mapped is 80

1. Go to **Policy & Objects > Objects> Virtual IPs** and select **Create New**.
2. Fill out the fields with the following information.

VIP Type	IPv4
Name	Web1-VIP
Comments	Virtual IP for the Forum Webserver
Interface	wan1
Type	(This field can only be changed in the CLI)
Source Address Filter	<disabled>
External IP Address/Range	256.85.94.60
Mapped IP Address/Range	192.168.50.37
Port Forwarding	<enabled>
Protocol	TCP
External Service Port	80
Map to Port	80

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall vip
  edit Web1-VIP
    set comment "Virtual IP for the Forum Webserver"
```

```
      set extintf wan1
      set extip 256.85.94.60
      set mappedip 192.168.50.37
      set portforward enable
      set protocol tcp
      set extport 80
      set mapped port 80
   end
end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects> Virtual IPs.** Check that the virtual IP address has been added to the list and that it is correct.
2. Enter the following CLI command:

```
config firewall vip
   edit <the name of the vip that you wish to verify>
      show full-configuration
```

VIP group

The company has only a single external IP address but multiple servers with different functions running on its internal LAN that need to be accessed from the Internet.

- The external IP address of the company on wan1 is 256.34.56.149 (for example use only. Not a valid IP address)
- The webserver is on the internal LAN on 192.168.100.86
- The webserver needs to answer on ports 80 443
- The administration of the FortiGate firewall connects on port 4443 instead of 443
- There is are also a separate email server, FTP server, and Terminal Server for specialised applications.
- 2 Virtual IPs have been created to map 256.34.56.149 to 192.168.100.86 on ports 80 and 443. The names are webserver_80 and webserver_443 respectively.

1. Go to **Policy & Objects > Objects> Virtual IPs**and select *Create New* > *Virtual IP Group.*
2. Fill out the fields with the following information.

Type	IPv4 VIP Group
Name	WebServer_Grp
Comments	(Optional)
Interface	wan1
Members	webserver_80 webserver_443

3. Enter the following CLI command:

```
config firewall vipgrp
   edit WebServer_Grp
      set member "webserver_80" "webserver_443"
      next
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Virtual IPs.** Check that the virtual IP address group has been added to the list and that it is correct.
2. Enter the following CLI command:

```
config firewall vipgrp
   edit <the name of the vip that you wish to verify>
      show full-configuration
```

Example: IP pool

Your company has an application server on the internal network that sends out regular data updates to an offsite service. In order to make the service site more secure, they only accept connections from predefined IP address. If the external IP address of the FortiGate firewall interface were used that would mean that the service would be accepting sessions from just about any user in the network so a separate IP address need so be assigned for the Network Address Translation.

- The external address that will be used is one that has been assigned to the company by the ISP on WAN2
- The address is 256.100.42.129 (for example use only. Not a valid IP address)

The ARP interface cannot be set in the Web-based Manager but as this is the only path that the traffic will be coming from the outside this should not be an issue. The setting has been included in the CLI instructions so that you will now how to set it in a situation where you want the ARP replies to be answered only on a specific interface.

1. Go to **Policy & Objects > Objects > IP Pools**.
2. Fill out the fields with the following information:

IP Pool Type	IPv4 Pool
Name	App_Server1
Comments	Addresses assignment for this server only.
Type	One-to-One
External IP Range	256.100.42.129
ARP Reply	<enabled>

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall ippool
   edit App_Server1
      set comments ''Addresses assignment for this server only."
      set type one-to-one
      set arp-reply enable
      set arp-intf wan2
      set startip 256.100.42.129
      set endip 256.100.42.129
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > IP Pools**.
2. Check that the IP Pool has been added to the list of IP Pools and that the listed settings are correct.
3. Enter the following CLI command:

```
config firewall ippool
   edit <the name of the IP Pool you wish to verify>
      show full-configuration
```

Example: Central NAT table

The company has a server on the Development LAN that needs to communicate with a server at a remote site over the Internet. One of the restrictions on the communications between these systems is that the IP address and source port must be specific.

- The traffic going out on to the Internet must be NATed
- The traffic is coming from a server with the IP address 192.168.150.86
- An address called “app-server” has been created for the address 192.168.150.86 on the port1 interface
- The external interface must be 256.23.45.67
- An address called "app-server-ext" has been created for the address 256.23.45.67 on the wan1 interface
- The originating traffic from the server originates in the port range from 2000 to 3000
- The remote site requires that the source TCP port must be within the 12000 to 13000 range

The original address and Translated Address fields require values that are address names that are listed in the address section of Firewall Objects.

1. Go to **Policy & Objects > Policy > Central NAT > Create New** .
2. Fill out the fields with the following information:

Source Address	app-server
Translated Address	app-server-ext
Original Source Port	2000
Translated Port	12000-13000

3. Select **OK**.
4. Enter the following CLI command:

```
config firewall central-nat
   edit 0
      set orig-addr app-server
      set nat-ippool app-server-ext
      set orig-port 2000
      set nat-port 12000-13000
      next
   end
```

To verify that the table was added correctly:

1. Go to **Policy & Objects > Policy > Central NAT**.
2. Check that the table has been added to the list of Central NAT Tables and that the listed settings are correct.

3. Enter the following CLI command:

```
config firewall central-nat
   show full-configuration
```

4. Verify that the listing of tables includes the one that you have just configured, with the correct settings.

When configuring the Central NAT in the GUI you may notice that only those addresses which have been configured to be associated with **any** interface are displayed in the drop down menu for choosing a Source Address and yet the CLI will allow any address to be used, not just those associated with **any** interface. This is because by default the policies in the GUI use a function of cross referencing which addresses are allowed based on which interface is involved in the policy. When combined with the aspect of Central NAT that doesn't restrict to a specific interface. This means the only addresses will be allowed are those associated with the **any** interface. The CLI does not have this cross referencing function which is why the CLI seems less restrictive. However, more care must be taken when using the CLI to make sure that appropriate addresses are used.

Example: Firewall schedule - recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 9, Minute = 0
Stop Time	Hour = 12, Minute = 0

4. Select **OK**.
5. Enter the following CLI command:

```
config firewall schedule recurring
   edit Morning_Business_Hours
      set day monday tuesday wednesday thursday friday
      set start 09:00
      set end 12:00
   end
```

6. Create a second new schedule.

Type	Recurring
Name	Morning_Business_Hours
Days	Monday, Tuesday, Wednesday, Thursday, Friday
Start Time	Hour = 13, Minute = 0
Stop Time	Hour = 18, Minute = 0

7. Select **OK**.
8. Enter the following CLI command:

```
config firewall schedule recurring
   edit Afternoon_Business_Hours
      set day monday tuesday wednesday thursday friday
      set start 13:00
      set end 18:00
   end
```

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.
3. Enter the following CLI command:

```
config firewall schedule recurring
   edit <the name of the schedule you wish to verify>
      show full-configuration
```

Example: Firewall schedule - one-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule**.
3. Fill out the fields with the following information:

Type	One-time
Name	NewYearsEve_Maintenance
Start Date	2014/12/31 <use the built in calendar>
End Date	2015/01/01 <use the built in calendar>
Start Time	Hour: 23, Minute: 0
Stop Time	Hour: 1Minute: 0

Pre-expiration event log	<disable>

4. Select **OK**.
5. Enter the following CLI command:

```
config firewall schedule onetime
   edit maintenance_window
      set start 23:00 2012/12/31
      set end 01:00 2013/01/01
      next
   end
```

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.
3. Enter the following CLI command:

```
config firewall schedule onetime
   edit <the name of the schedule you wish to verify>
      show full-configuration
   group you wish to verify>
      show full-configuration
```

Example: Schedule group

In order to make the administration of the policies easier a group needs to be created.

1. Go to **Policy & Objects > Objects > Schedule**.
2. Select **Create New > Schedule Group**.
3. Fill out the fields with the following information:

Name	Business_Hours
Members	Morning_Business_Hours Afternoon_Business_Hours

4. Select **OK**.
5. Enter the following CLI command:

```
config firewall service group
   edit Business_Hours
      set member Morning_Business_Hours Afternoon_Business _ours
   end
```

To verify that the schedule was added correctly:

1. Go to **Policy & Objects > Objects > Schedule**.
2. Check that the schedule group with the name you used has been added to the list of schedule groups.
3. Enter the following CLI command:

```
config firewall service group
   edit <the name of the schedule
```

Example: Proxy option

The company will be using a number of the Security Profiles features on various policies but wants to use as few profiles as possible to make administration simpler. The decision has been made to have two profiles, the default one and a single customized one that will be a combination of the settings required to cover the situations that will not be covered by the default profile.

The company profile will have the following parameters:

- There are no FTP servers running on the site so there is no need for FTP.
- The company has a non-standard IMAP implementation the uses port 1143.
- The Comfort Clients is to be used with a ratio of 1 byte for every 15 seconds.
- There is a lot of varied email traffic so there is to be no blocking of emails due to size beyond the settings on the mail servers.

1. Go to **Policy & Objects > Policy > Proxy Options**.
2. Create a new profile
3. Fill out the fields with the following information:

Name	example_standard
Comments	<optional>
Log Oversized Files	<disabled>

Protocol port mapping:

Enable	Protocol	Inspection Ports
enabled	HTTP	Specify and <leave on default setting.>
enabled	SMTP	Specify and <leave on default setting.>
enabled	POP3	Specify and <leave on default setting.>
enabled	IMAP	Specify and 1143
not enabled	FTP	
enabled	NNTP	Specify and <leave on default setting.>
enabled	MAPI	<leave on default setting.>
enabled	DNS	<leave on default setting.>

Common options

Comfort Clients	enabled
Interval (Seconds)	15
Amount(bytes)	1
Block Oversized File/Email	not enabled
Threshold(MB)	not enabled

Web options

Enabled Chunked Bypass	not enabled
Add Fortinet Bar	not enabled
Communication Port	<Unseen because Add Fortinet Bar is not enabled>

Email Options

Allow Fragmented Messages	<not enabled>
Append Signature (SMTP)	<not enabled>
Email Signature Text	<Unseen because Append Signature is not enabled>

4. Select **OK**.
5. Enter the following CLI command:

```
config firewall profile-protocol-options
   edit example_standard
      config http
         set options clientcomfort no-content-summary
         set comfort-interval 15
         next
      config ftp
         set status disable
         set options clientcomfort no-content-summary splice
         set comfort-interval 15
         next
      config imap
         set ports "1143"
         set options fragmail no-content-summary
         next
      config mapi
         set options fragmail no-content-summary
         next
      config pop3
         set options fragmail no-content-summary
```

```
    next
  config smtp
    set options fragmail no-content-summary splice
    next
  config nntp
    set options no-content-summary splice
    next
  config ssh
    set inspect-all enable
    set log x11-filter ssh-shell exec port-forward
    next
  end
```

Oversized files

A couple of variations on the example could have to do with the processing of oversized files at a level other than the default setting. The ways that it can be approached are:

Set a non default threshold size and block the files

Set a non default threshold size and not scan the files over the threshold but allow them to pass through the FortiGate firewall.

In the following instructions:

- We will just use 2 MB as the new threshold.
- In the CLI instructions we will limit the configuration to just the HTTP settings for the purposes of brevity and simplicity.

Option 1

Option 1 can be done in the GUI.

1. Go to **Policy & Objects > Policy > Proxy Options**.
2. Edit the profile that you wan the change in.
3. Fill out the fields with the following information:

Common Options

Comfort Clients	enabled
Interval (Seconds)	15
Amount(bytes)	1
Block Oversized File/Email	enabled
Threshold(MB)	2

4. Select **OK**.
5. Enter the following CLI command:

```
config firewall profile-protocol-options
  edit example_standard
    config http
```

```
      set options clientcomfort no-content-summary oversize
      set oversize-limit 2
      set comfort-interval 15
      next
   end
```

Option 2

Option 2 can only be done in the CLI. Enter the following CLI command:

```
config firewall profile-protocol-options
   edit example_standard
      config http
         set options clientcomfort no-content-summary
         set oversize-limit 2
         set comfort-interval 15
         next
      end
```

Example: DoS policy

The company wishes to protect against Denial of Service attach. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The tcp_syn_flood attach's threshold is to be changed from the default to 1000

1. Go to **Policy & Objects > Policy > DoS**.
2. Create a new policy
3. Fill out the fields with the following information:

Incoming Interface	wan1
Source Address	all
Destination Addresses	all
Service	ALL

Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>
udp_scan	enabled	enabled	Pass	<default value>
udp_src_session	enabled	enabled	Pass	<default value>
udp_dst_session	enabled	enabled	Pass	<default value>
icmp_flood	enabled	enabled	Pass	<default value>
icmp_sweep	enabled	enabled	Pass	<default value>
icmp_src_session	enabled	enabled	Pass	<default value>
icmp_dst_session	enabled	enabled	Pass	<default value>
ip_src_session	enabled	enabled	Pass	<default value>
ip_dst_session	enabled	enabled	Pass	<default value>
sctp_flood	not enabled	not enabled	Pass	<default value>
sctp_scan	not enabled	not enabled	Pass	<default value>
sctp_src_session	not enabled	not enabled	Pass	<default value>
sctp_dst_session	not enabled	not enabled	Pass	<default value>

4. Toggle the button next to **Enable this policy** to **ON**.
5. Select **OK**.
6. Enter the following CLI command:

```
config firewall DoS-policy
   edit 0
      set status enable
      set interface ''
      config anomaly
         edit "tcp_syn_flood"
            set status enable
            set log enable
            set action block
```

```
      set threshold 1000
      next
   edit "tcp_port_scan"
      set status enable
      set log enable
      set action block
      next
   edit "tcp_src_session"
      set status enable
      set log enable
      set action block
      next
   edit "tcp_dst_session"
      set status enable
      set log enable
      set action block
   next
      edit "udp_flood"
      set status enable
      set log enable
   next
      edit "udp_scan"
      set status disable
      set status enable
      set log enable
      next
   edit "udp_src_session"
      set status enable
      set log enable
      next
   edit "udp_dst_session"
      set status enable
      set log enable
      next
   edit "icmp_flood"
      set status enable
      set log enable
      next
   edit "icmp_sweep"
      set status enable
      set log enable
      next
   edit "icmp_src_session"
      set status enable
      set log enable
      next
   edit "icmp_dst_session"
      set status enable
      set log enable
      next
   edit "ip_src_session"
      set status enable
      set log enable
      next
   edit "ip_dst_session"
      set status enable
      set log enable
```

```
        next
      end
    next
  end
```

Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate units support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate unit interface is connected. Multicast routing is not supported in transparent mode (TP mode).

To support PIM communications, the sending/receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. In addition, if a FortiGate unit is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate unit, the FortiGate unit can perform any of these functions at any time as configured.

Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate unit interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
   set multicast-routing {enable | disable}
      config interface
         edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
         end
      config pim-sm-global
         config rp-address
            edit <index>
               set ipv6-address <ipv6-address>
            end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM

routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers—PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate units operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate unit to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. The following table lists the reserved multicast address ranges and describes what they are reserved for:

Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to **Firewall Objects > Address > Addresses** and selecting **Create New > Multicast Address**. The factory default configuration includes multicast addresses for Bonjour (224.0.0.251-224.0.0.251, EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all_hosts (224.0.0.1-224.0.0.1), and all_routers (224.0.0.2-224.0.0.2).

PIM Support

A FortiGate unit can be configured to support PIM by going to **Router > Dynamic > Multicast** and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI

command. When PIM is enabled, the FortiGate unit allocates memory to manage mapping information. The FortiGate unit communicates with neighboring PIM routers to acquire mapping information and if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio/video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end-user could type in a class D multicast group address, an alias for the multicast group address, or a call-conference number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them — end-users may use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there is no way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end-users may switch to a different multicast address).

To configure a PIM domain

1. If you will be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you will be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate units, use the `config router multicast` command to set global operating parameters.
5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interface(s).

Multicast forwarding and FortiGate units

In both transparent mode and NAT mode you can configure FortiGate units to forward multicast traffic.

For a FortiGate unit to forward multicast traffic you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that is accepted based on source and destination address, and to perform NAT on multicast packets.

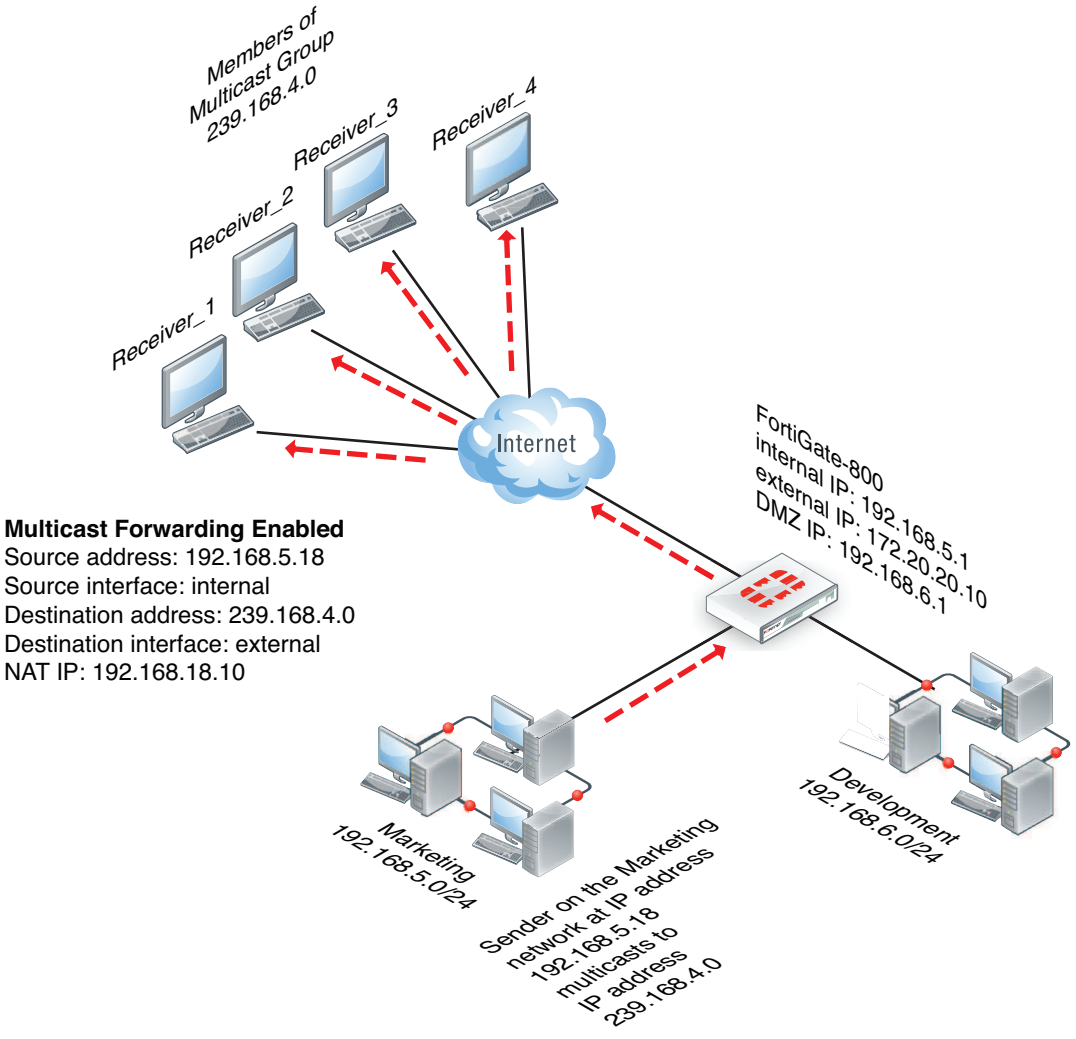
In the example shown below, a multicast source on the Marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate unit, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate unit is not acting as a multicast router.

Multicast forwarding and RIPv2

RIPv2 uses multicast to share routing table information. If your FortiGate unit is installed on a network that includes RIPv2 routers, you must configure the FortiGate unit to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate unit. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate unit to forward multicast packets.

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate unit you can add standard security policies. Security policies to accept RIPv1 packets can use the ANY predefined firewall service or the RIP pre-defined firewall service.

Example multicast network including a FortiGate unit that forwards multicast packets



Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding from the Command Line Interface (CLI). Two steps are required:

- Adding multicast security policies
- Enabling multicast forwarding
  This second step is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There is sometimes a confusion between the terms “forwarding” and “routing”. These two functions should not be taking place at the same time.

It is mentioned that multicast-forward should be enabled when the FortiGate unit is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter should **NOT** be enabled when the FortiGate unit operates as a multicast router (i.e. with a routing protocol enabled. It should only be enabled when there is no routing protocols activated.

Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and optionally the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and Destination interfaces are optional. If left blank, then the multicast will be forwarded to ALL interfaces.
- Source and Destination addresses are optional. If left un set, then it will mean ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, the FortiGate unit forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

Enter the following CLI command to enable multicast forwarding:

```
config system settings
   set multicast-forward enable
end
```

If multicast forwarding is disabled and the FortiGate unit drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate unit does not increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
   set multicast-ttl-notchange enable
end
```

In transparent mode, the FortiGate unit does not forward frames with multicast destination addresses. Multicast traffic such as the one used by routing protocols or streaming media may need to traverse the FortiGate unit, and should not be interfere with the communication. To avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

The CLI parameter multicast-skip-policy must be disabled when using multicast security policies. To disable enter the command

```
config system settings
     set multicast-skip-policy disable
end
```

In this simple example, no check is performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

To enable the multicast policy

```
config firewall multicast-policy
   edit 1
      set action accept
   end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

To enable the restrictive multicast policy

```
config firewall multicast-policy
   edit 1
      set srcintf wan1
      set dstinf internal
      set action accept
   end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129, which is represented by the address object "example_addr-1".

To enable the restrictive multicast policy

```
config firewall multicast-policy
   edit 1
      set srcintf wan1
      set srcaddr example_addr-1
      set dstinf internal
      set action accept
   end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address

range 239.168.4.0. The policy allows the multicast packets to enter the internal interface and then exit the external interface. When the packets leave the external interface their source address is translated to 192.168.18.10

```
config firewall multicast-policy
   edit 5
      set srcaddr 192.168.5.18 255.255.255.255
      set srcintf internal
      set destaddr 239.168.4.0 255.255.255.0
      set dstintf external
      set nat 192.168.18.10
   end
```

This example shows how to configure a multicast security policy so that the FortiGate unit forwards multicast packets from a multicast Server with an IP 10.10.10.10 is broadcasting to address 225.1.1.1. This Server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
   edit 1
      set srcintf DMZ
      set srcaddr 10.10.10.10 255.255.255.255
      set dstintf Internal
      set dstaddr 225.1.1.1 255.255.255.255
      set action accept
   edit 2
      set action deny
   end
```

Multicast routing examples

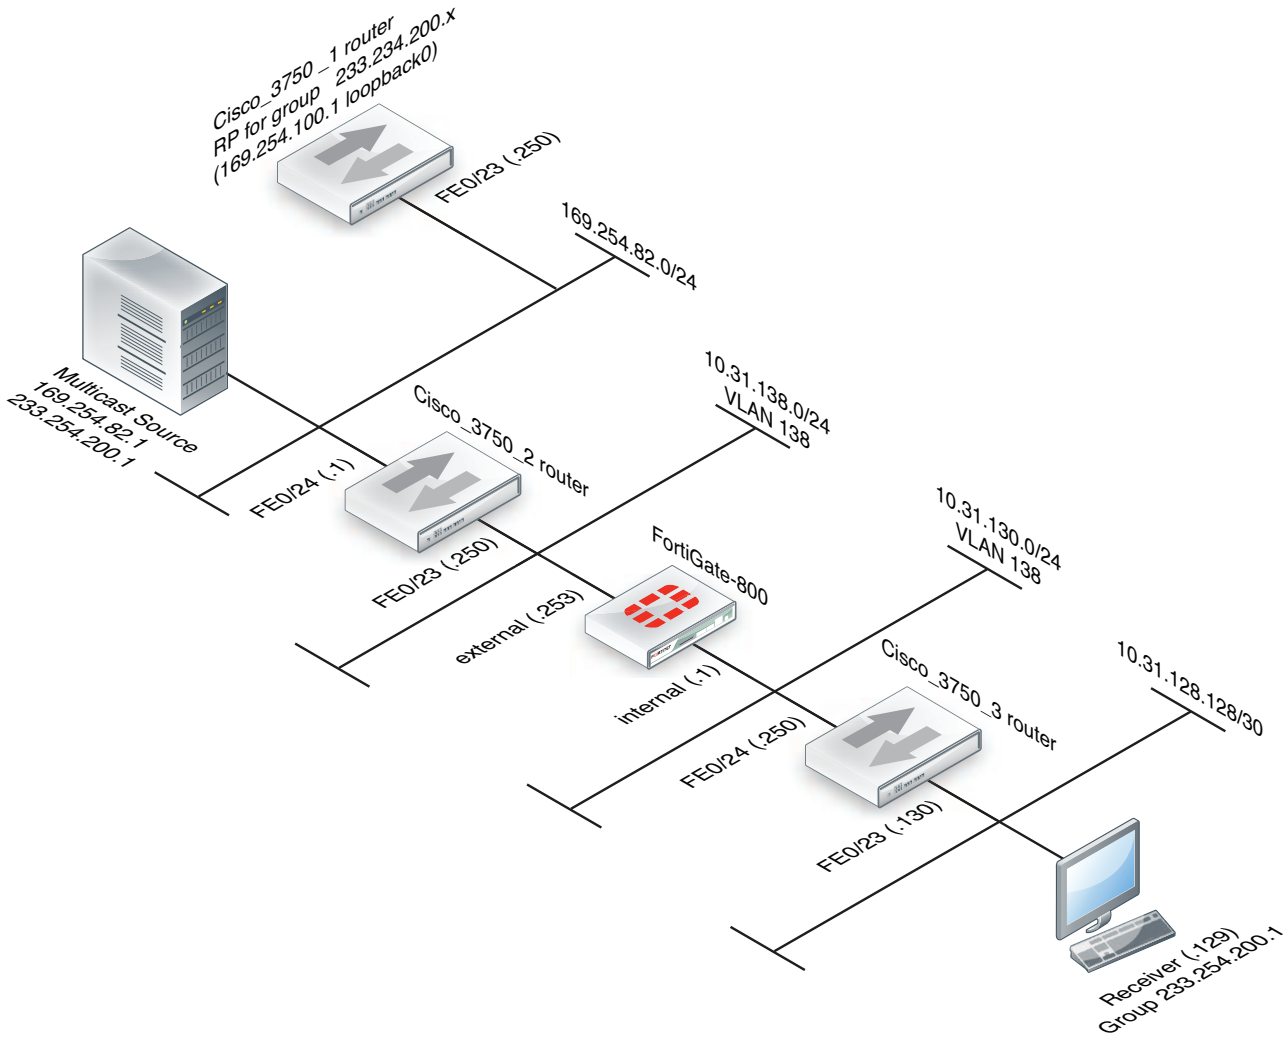
This section contains the following multicast routing configuration examples and information:

- Example FortiGate PIM-SM configuration using a static RP
- FortiGate PIM-SM debugging examples
- Example multicast destination NAT (DNAT) configuration
- Example PIM configuration that uses BSR to find the RP

Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown below has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

Example FortiGate PIM-SM topology



The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco_3750_1. Using a bootstrap router (BSR) was not tested in this example. See “Example PIM configuration that uses BSR to find the RP” for an example that uses a BSR.

Configuration steps

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- Cisco_3750_1 router configuration
- Cisco_3750_2 router configuration
- To configure the FortiGate-800 unit
- Cisco_3750_3 router configuration

Cisco_3750_1 router configuration

```
version 12.2
```

```
!

```

To configure the FortiGate-800 unit

1. Configure the internal and external interfaces.

- **Internal**

  Go to **System > Network > Interfaces**.

  Select the internal interface.

  Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.138.253 255.255.255.0
Administrative Access:	PING

  Select **OK**.

- **External**

  Go to **System > Network > Interfaces**.

Select the external interface.

Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.130.253 255.255.255.0
Administrative Access:	HTTPS and PING

Select **OK**.

2. Add a firewall addresses.

Go to **Policy & Objects> Objects > Addresses.**

- RP

Select **Create New**.

Use the following settings:

Category:	Address
Name:	RP
Type:	Subnet
Subnet/IP Range:	169.254.100.1/32
Interface:	Any
Visibility:	<enabled>

Select **OK**.

- Multicast source subnet

Select **Create New**.

Use the following settings:

Category:	Address
Name:	multicast_source_subnet
Type:	Subnet
Subnet/IP Range:	169.254.82.0/24
Interface:	Any
Visibility:	<enabled>

Select **OK**.

3. Add destination multicast address

   Go to **Policy & Objects> Objects > Addresses.**

   Select **Create New**.

   Use the following settings:

Category:	Multicast Address
Name:	Multicast_stream
Type:	Broadcast Subnet
Broadcast Subnet:	233.254.200.0/24
Interface:	Any
Visibility:	<enabled>

   Select **OK**.

4. Add standard security policies to allow traffic to reach the RP.

   Go to **Policy & Objects > Policy > IPv4**.

   - 1st policy

   Select **Create New**

   Use the following settings:

Incoming Interface:	internal
Source Address:	all
Outgoing Interface:	external
Destination Address:	RP
Schedule:	always
Service:	ALL
Action:	ACCEPT

   Select **OK**.

   - 2nd policy

   Select **Create New**

   Use the following settings:

Incoming Interface:	external

Source Address:	RP
Outgoing Interface:	internal
Destination Address:	all
Schedule:	always
Service:	ALL
Action:	ACCEPT

Select **OK**.

5. Add the multicast security policy.

   Go to **Policy & Objects > Policy > Multicast**.

   Select **Create New**.

   Use the following settings:

Incoming Interface:	external
Source Address:	multicast_source_subnet
Outgoing Interface:	internal
Destination Address:	multicast_stream
Protocol:	Any
Action:	ACCEPT

   Select **OK**.

6. Add an access list. (CLI only)

```
config router access-list
   edit Source-RP
      config rule
         edit 1
            set prefix 233.254.200.0 255.255.255.0
            set exact-match disable
         next
      end
```

7. Add some static routes.

   Go to **Router > Static > Static Routes**.

   - Route 1

   Select **Create New**.

   Use the following settings:

Destination IP/Mask:	0.0.0.0/0.0.0.0
Device:	internal
Gateway:	10.31.130.250
Distance:	<default>
Priority:	<default>

Select **OK**.

- Route 2

Select **Create New**.

Use the following settings:

Destination IP/Mask:	169.254.0.0/16
Device:	external
Gateway:	10.31.138.250
Distance:	<default>
Priority:	<default>

Select **OK**.

8. Configure multicast routing.

   Go to **Router > Dynamic > Multicast**.

   Add the following Static Rendezvous Point(s):
   - 169.254.100.1

   - Route 1

   Select **Create New**.

   Use the following settings:

Interface:	internal
PIM Mode:	Sparse Mode
DR Priority:	<not needed in this scenario>
RP Candidate:	<not needed in this scenario>
RP Candidate Priority:	<not needed in this scenario>

   Select **OK.**

   - Route 2

Select **Create New**.

Use the following settings:

Interface:	external
PIM Mode:	Sparse Mode
DR Priority:	
RP Candidate:	
RP Candidate Priority:	

Select **OK.**

Cisco_3750_3 router configuration

```
version 12.2
!
hostname Cisco-3750-3
!
switch 1 provision ws-c3750-24ts
ip subnet-zero
ip routing
!
ip multicast-routing distributed
!
spanning-tree mode pvst
no spanning-tree optimize bpdu transmission
spanning-tree extend system-id
!
interface FastEthernet1/0/23
   switchport access vlan 128
   switchport mode access
!
interface FastEthernet1/0/24
   switchport access vlan 130
   switchport mode access
!
interface Vlan128
   ip address 10.31.128.130 255.255.255.252
   ip pim sparse-mode
   ip mroute-cache distributed
!
interface Vlan130
   ip address 10.31.130.250 255.255.255.0
   ip pim sparse-mode
   ip mroute-cache distributed
!
ip classless

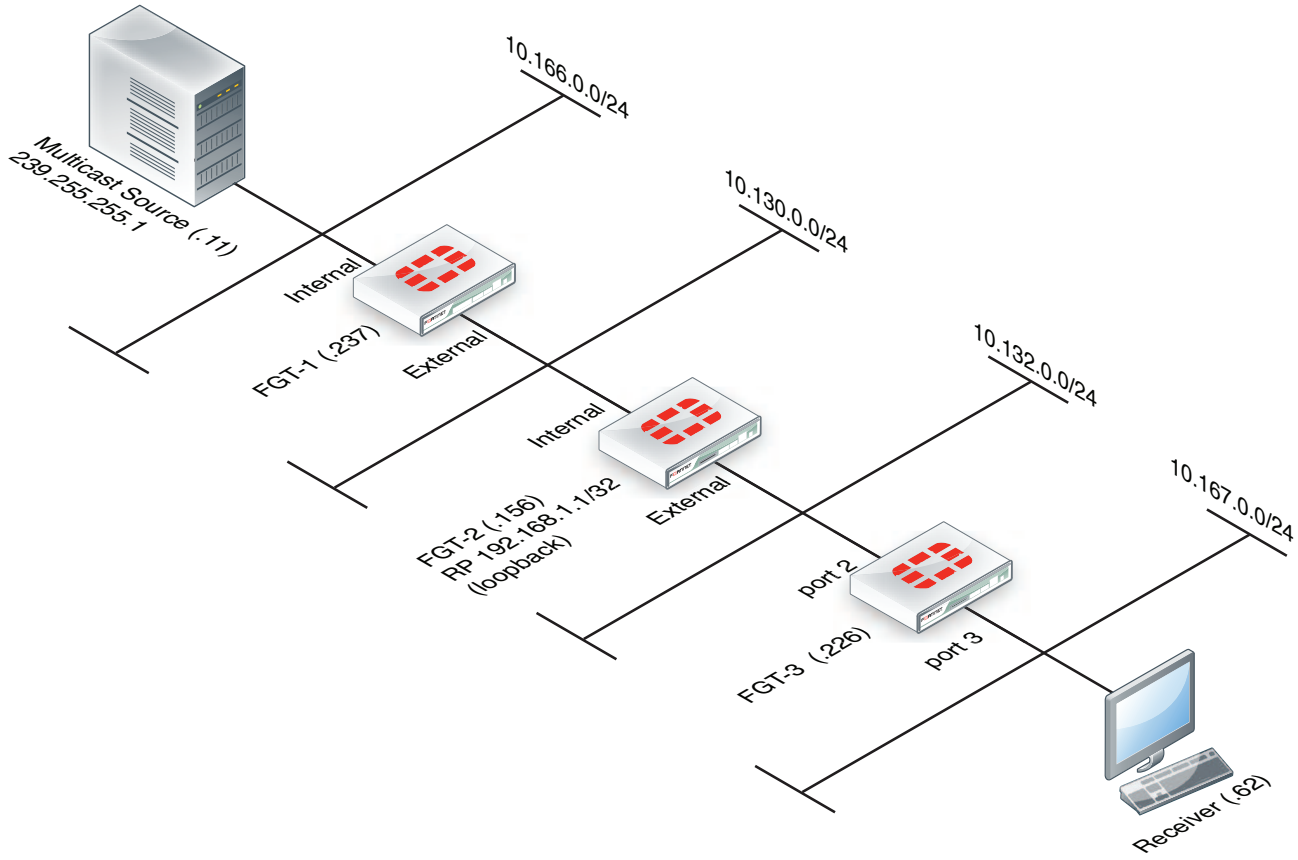
ip http server
ip pim rp-address 169.254.100.1 Source-RP
!
!
ip access-list standard Source-RP
```

```
permit 233.254.200.0 0.0.0.255
```

FortiGate PIM-SM debugging examples

Using the example topology shown below, you can trace the multicast streams and states within the three FortiGate units (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from FortiGate unit when the multicast stream is flowing correctly from source to receiver.

PIM-SM debugging topology



Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```
FGT-3 # get router info multicast igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires Last Reporter
239.255.255.1 port3 00:31:15 00:04:02 10.167.0.62
```

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active the expire time should drop to approximately 2 minutes before being refreshed.

Checking the PIM-SM neighbors

Next the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3.

```
FGT-3 # get router info multicast pim sparse-mode neighbour
Neighbor Interface Uptime/Expires Ver DR
Address Priority/Mode
10.132.0.156 port2 01:57:12/00:01:33 v2 1 /
```

Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the `*,G` join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
RP: 192.168.1.1
Uptime: 07:23:00
```

Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

(*,*,RP) Entries	This state may be reached by general joins for all groups served by a specified RP.
(*,G) Entries	State that maintains the RP tree for a given group.
(S,G) Entries	State that maintains a source-specific tree for source `S` and group `G`.
(S,G,rpt) Entries	State that maintains source-specific information about source s on the RP tree for `G`. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree.
FCR	The FCR state entries are for tracking the sources in the <*, G> when <S, G> is not available for any reason, the stream would typically be flowing when this state exists.

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
```

```
Upstream State: JOINED
Local:
port3
Joined:
Asserted:
FCR:
```

The RP will always be listed in a `*,G` entry, the RPF neighbor and interface index will also be shown. In this topology these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
Asserted:
Outgoing:
port3
```

This is the entry for the SPT, no RP IS listed. The `S,G` stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
Local:
Pruned:
Outgoing:
```

The above `S,G,RPT` state is created for all streams that have both a `S,G` and a `*,G` entry on the router. This is not pruned in this case because of the topology, the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams

```
FGT-3 # get router info multicast pim sparse-mode next-hop
Flags: N = New, R = RP, S = Source, U = Unreachable
Destination Type Nexthop Nexthop Nexthop Metric Pref Refcnt
Num Addr Ifindex
_____________________________________________________________
10.166.0.11 ..S. 1 10.132.0.156 9 21 110 3
192.168.1.1 .R.. 1 10.132.0.156 9 111 110 2
```

Viewing the PIM multicast forwarding table

Also you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
Incoming interface: port2
Outgoing interface list:
port3 (TTL threshold 1)
```

Viewing the kernel forwarding table

Also the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[ ] status=resolved
last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
index(ttl)=[6(1),]
```

Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2 there are some small differences:

```
FGT-2 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0

(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: JOINED
Local:
Joined:
external
Asserted:
FCR:
```

The `*,G` entry now has a joined interface rather than local because it has received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
```

```
Asserted:
Outgoing:
external
```

The S,G entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
Local:
Pruned:
Outgoing:
External
```

The S,G,RPT is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states, there is no *,G entry because it is not in the path of a receiver and the RP.

```
FGT-1_master # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

Below the S,G is the SPT termination because this FortiGate unit is the first hop router, the RPF neighbor always shows as 0.0.0.0 because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
Local:
Joined:
external
Asserted:
Outgoing:
external
```

The stream has been pruned back from the RP because the end-to-end SPT is flowing, there is no requirement for the stream to be sent to the RP in this case.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external
Upstream State: RPT NOT JOINED
Local:
Pruned:
Outgoing:
```

Example multicast destination NAT (DNAT) configuration

The example topology shown and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example the FortiGate units have the following roles:

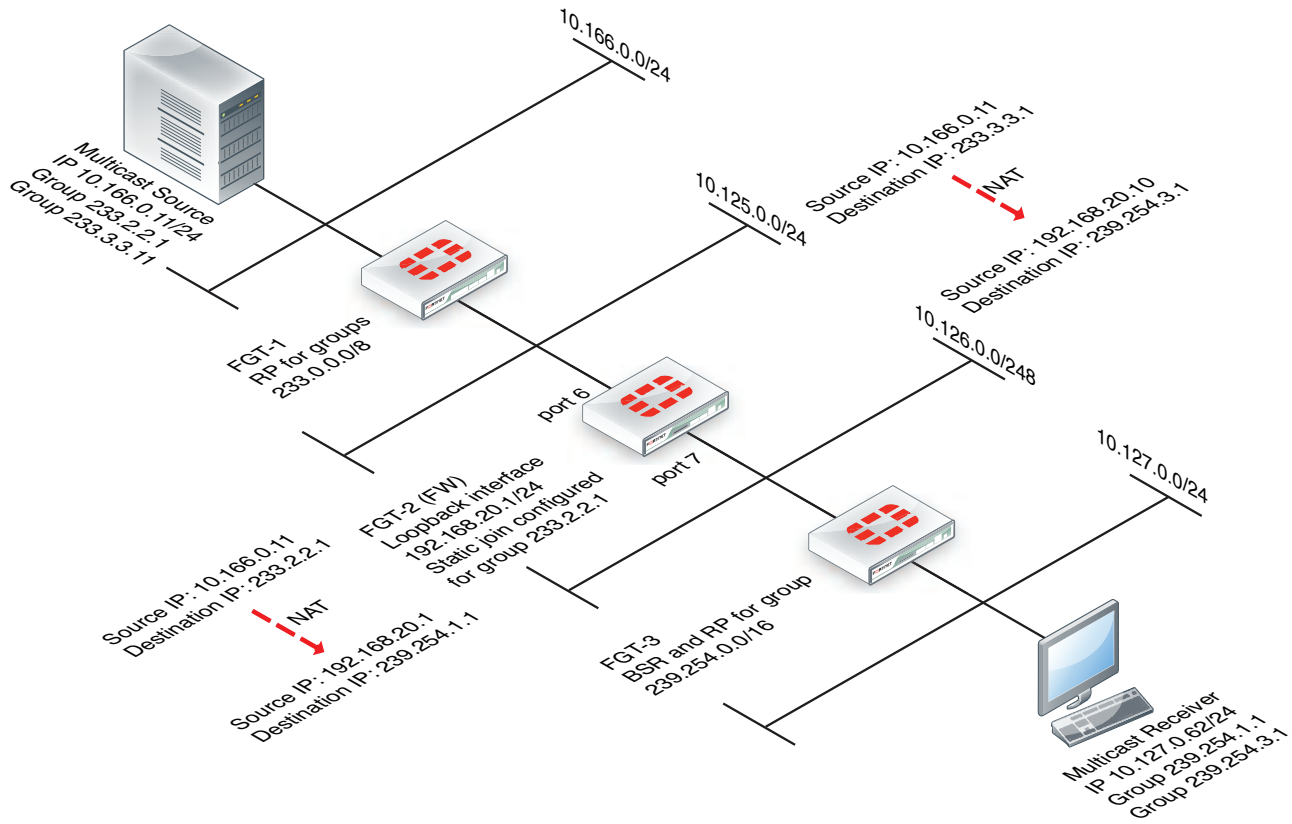
- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1; FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1; FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

Example multicast DNAT topology



To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named `loopback`.

```
config system interface
   edit loopback
      set vdom root
      set ip 192.168.20.1 255.255.255.0
      set type loopback
   next
end
```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also add static joins to the loopback interface for any groups to be translated.

```
config router multicast
   config interface
      edit loopback
         set pim-mode sparse-mode
            config join-group
               edit 233.2.2.1
               next
               edit 233.3.3.1
               next
            end
      next
```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```
config firewall ippool
   edit Multicast_source
      set endip 192.168.20.20
      set interface port6
      set startip 192.168.20.10
   next
end
```

4. Add the translation security policies.

   Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool. The source and destination addresses will need to be previously created address objects. For this example, 233.3.3.1 255.255.255.255 will be represented by "example-addr_1" and 10.166.0.11 255.255.255.255 will be represented by "example-addr_2". You will likely want to use something more intuitive from your own network.

```
config firewall multicast-policy
   edit 1
      set dnat 239.254.3.1
      set dstaddr example-addr_1
      set dstintf loopback
      set nat 192.168.20.10
      set srcaddr example-addr_2
      set srcintf port6
   next
   edit 2
      set dnat 239.254.1.1
      set dstaddr 233.2.2.1 255.255.255.255
      set dstintf loopback
      set nat 192.168.20.1
```

```
      set srcaddr 10.166.0.11 255.255.255.255
      set srcintf port6
   next
end
```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

   This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate unit.

```
config firewall multicast-policy
   edit 3
      set dstintf port7
      set srcintf loopback
   next
end
```

Example PIM configuration that uses BSR to find the RP

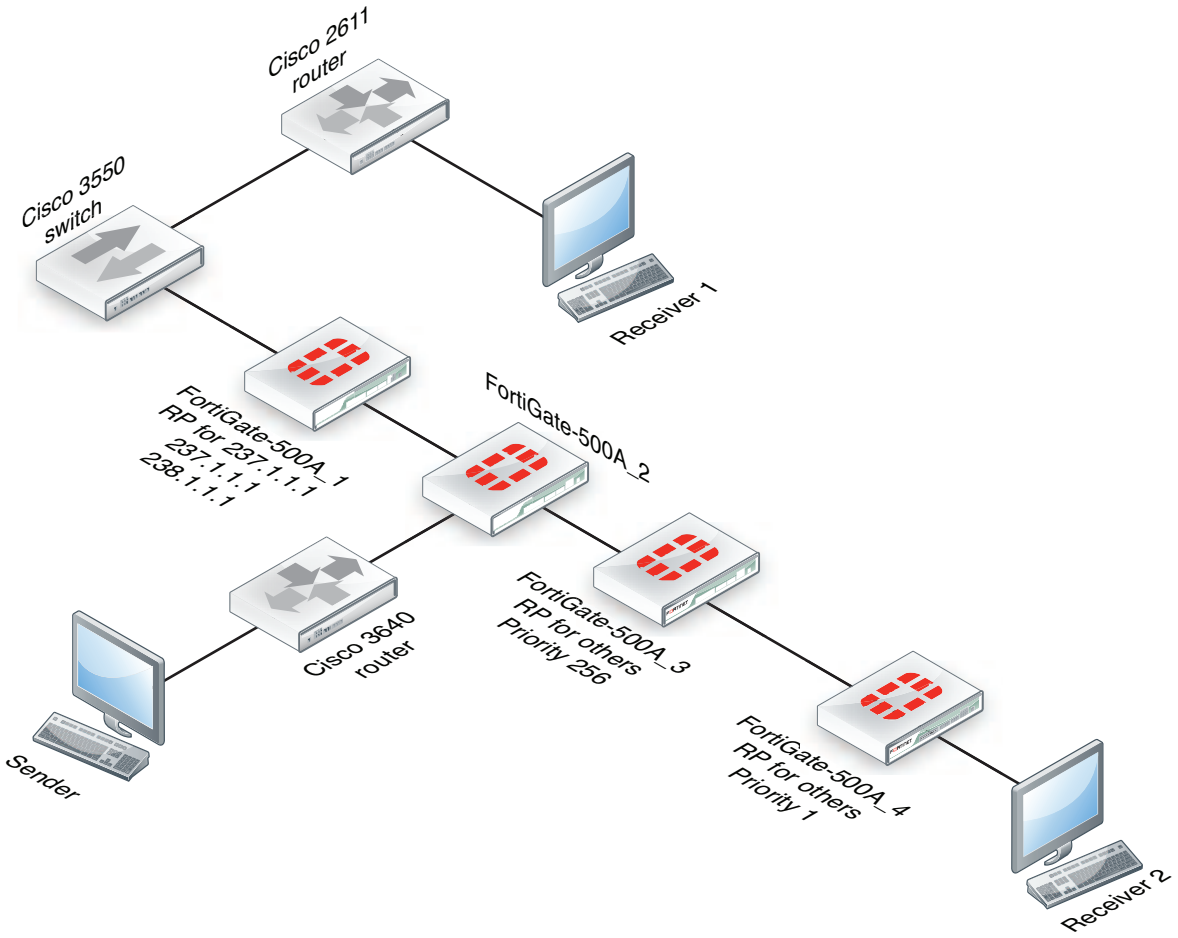
This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A units (FortiGate-500A_1 to FortiGate-550A_4). A multicast sender is connected to FortiGate-500A_2. FortiGate-500A_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

This example describes:

- Commands used in this example
- Configuration steps
- Example debug commands

PIM network topology using BSR to find the RP



Commands used in this example

This example uses CLI commands for the following configuration settings:

- Adding a loopback interface (lo0)
- Defining the multicast routing
- Adding the NAT multicast policy

Adding a loopback interface (lo0)

Where required, the following command is used to define a loopback interface named `lo0`.

```
config system interface
   edit lo0
      set vdom root
      set ip 1.4.50.4 255.255.255.255
      set allowaccess ping https ssh snmp http telnet
      set type loopback
   next
end
```

Defining the multicast routing

In this example, the following command syntax is used to define multicast routing.

The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

```
config router multicast
   config interface
      edit port6
         set pim-mode sparse-mode
      next
      edit port1
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
            config join-group
               edit 236.1.1.1
               next
            end
         set rp-candidate-priority 1
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-allow-quick-refresh enable
      set bsr-candidate enable
      set bsr-interface lo0
      set bsr-priority 200
   end
end
```

Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation.

The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
   edit 1
      set dstintf port6
      set srcintf lo0
   next
   edit 2
      set dnat 238.1.1.1
      set dstintf lo0
      set nat 1.4.50.4
      set srcintf port1
   next
```

Configuration steps

In this sample, FortiGate-500A_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A_4 is the RP for the other group which has a priority of1. OSPF is used in this example to distribute routes including the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A_4, configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well.

The following procedures include the CLI commands for configuring each of the FortiGate units in the example configuration.

To configure FortiGate-500A_1

1. Configure multicast routing.

```
config router multicast
   config interface
      edit port5
         set pim-mode sparse-mode
      next
      edit port4
         set pim-mode sparse-mode
      next
      edit lan
         set pim-mode sparse-mode
      next
      edit port1
         set pim-mode sparse-mode
      next
      edit lo999
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
         set rp-candidate-group 1
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
   end
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
   edit 1
      set dstintf port5
      set srcintf port4
   next
   edit 2
      set dstintf port4
      set srcintf port5
   next
```

```
      edit 3
      next
   end
```

3. Add router access lists.

```
   config router access-list
      edit 1
         config rule
            edit 1
               set prefix 228.1.1.1 255.255.255.255
               set exact-match enable
            next
            edit 2
               set prefix 237.1.1.1 255.255.255.255
               set exact-match enable
            next
            edit 3
               set prefix 238.1.1.1 255.255.255.255
               set exact-match enable
            next
         end
      next
   end
```

To configure FortiGate-500A_2

1. Configure multicast routing.

```
   config router multicast
      config interface
         edit "lan"
            set pim-mode sparse-mode
next
edit "port5"
  set pim-mode sparse-mode
            next
            edit "port2"
               set pim-mode sparse-mode
            next
            edit "port4"
               set pim-mode sparse-mode
            next
            edit "lo_5"
               set pim-mode sparse-mode
                  config join-group
                     edit 236.1.1.1
                     next
                  end
               next
            end
         set multicast-routing enable
      end
```

2. Add multicast security policies.

```
   config firewall multicast-policy
      edit 1
         set dstintf lan
```

```
      set srcintf port5
    next
    edit 2
      set dstintf port5
      set srcintf lan
    next
    edit 4
      set dstintf lan
      set srcintf port2
    next
    edit 5
      set dstintf port2
      set srcintf lan
    next
    edit 7
      set dstintf port1
      set srcintf port2
    next
    edit 8
      set dstintf port2
      set srcintf port1
    next
    edit 9
      set dstintf port5
      set srcintf port2
    next
    edit 10
      set dstintf port2
      set srcintf port5
    next
    edit 11
      set dnat 237.1.1.1
      set dstintf lo_5
      set nat 5.5.5.5
      set srcintf port2
    next
    edit 12
      set dstintf lan
      set srcintf lo_5
    next
    edit 13
      set dstintf port1
      set srcintf lo_5
    next
    edit 14
      set dstintf port5
      set srcintf lo_5
    next
    edit 15
      set dstintf port2
      set srcintf lo_5
    next
    edit 16
    next
end
```

To configure FortiGate-500A_3

1. Configure multicast routing.

```
config router multicast
   config interface
      edit port5
         set pim-mode sparse-mode
      next
      edit port6
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
         set rp-candidate-priority 255
      next
      edit lan
         set pim-mode sparse-mode
      next
   end
set multicast-routing enable
   config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
   end
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
   edit 1
      set dstintf port5
      set srcintf port6
   next
   edit 2
      set dstintf port6
      set srcintf port5
   next
   edit 3
      set dstintf port6
      set srcintf lan
   next
   edit 4
      set dstintf lan
      set srcintf port6
   next
   edit 5
      set dstintf port5
      set srcintf lan
   next
   edit 6
      set dstintf lan
      set srcintf port5
   next
end
```

To configure FortiGate-500A_4

1. Configure multicast routing.

```
config router multicast
   config interface
      edit port6
         set pim-mode sparse-mode
      next
      edit lan
         set pim-mode sparse-mode
      next
      edit port1
         set pim-mode sparse-mode
      next
      edit lo0
         set pim-mode sparse-mode
         set rp-candidate enable
            config join-group
               edit 236.1.1.1
               next
            end
         set rp-candidate-priority 1
      next
   end
set multicast-routing enable
   config pim-sm-global
set bsr-allow-quick-refresh enable
      set bsr-candidate enable
      set bsr-interface lo0
      set bsr-priority 1
   end
end
```

2. Add multicast security policies.

```
config firewall policy
   edit 1
      set srcintf lan
      set dstintf port6
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 2
      set srcintf port6
      set dstintf lan
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 3
      set srcintf port1
      set dstintf port6
      set srcaddr all
```

```
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 4
      set srcintf port6
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 5
      set srcintf port1
      set dstintf lan
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 6
      set srcintf lan
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 7
      set srcintf port1
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 8
      set srcintf port6
      set dstintf lo0
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 9
      set srcintf port1
      set dstintf lo0
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
```

```
      set service ANY
    next
    edit 10
      set srcintf lan
      set dstintf lo0
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY

Chapter 10 - FortiView

FortiView

This document provides a general guide to FortiView, the FortiOS log view tool, explaining its layout, features, and its usefulness in everyday administrative scenarios.

The following chapters are included in this document:

Overview on page 1 outlines the role FortiView plays in FortiOS and its overall layout. This section also identifies which FortiGate platforms support the full FortiView features.

Sources on page 1 explains the features of FortiView's Sources console, and shows how you can investigate an unusual spike in traffic to determine which user is responsible.

Applications on page 1 explains the features of FortiView's Applications console and shows how you can view what sort of applications their employees are using.

Cloud Applications on page 1 explains the features of FortiView's Cloud Applications console and shows how you can drill down to access detailed data on cloud application usage, e.g. YouTube.

Destinations on page 1 explains the features of FortiView's Destinations console and shows how you can access detailed information on user destination-accessing through the use of drill down functionality.

Web Sites on page 1 explains the features of FortiView's Web Sites console and shows how you can investigate instances of proxy avoidance which is the use of a proxy site in order to access data that might otherwise be blocked by the server.

Threats on page 1 explains the features of FortiView's Threats console and shows how you can monitor threats to the network, both in terms of their Threat Score and Threat Level.

All Sessions on page 1 explains the features of FortiView's All Sessions console and shows how you can filter sessions by port number and application type.

Reference on page 1 explains reference information for the various consoles in FortiView, and describes the assortment of filtering options, drilldown options, and columns available.

Troubleshooting FortiView on page 1 offers solutions to common technical issues experienced by FortiGate users.

Overview

This section provides an overview of FortiView, its interface, and options, including the following:

Enabling FortiView

By default, FortiView is enabled on FortiGates running FortiOS firmware version 5.2 and above. You will find the FortiView consoles under **System > FortiView**. However, certain options will not appear unless the FortiGate has **Disk Logging** enabled.

Only certain FortiGate models support Disk Logging. A complete list of FortiGate platforms that support Disk Logging is provided in the matrix below.

To enable Disk Logging

1. Go to **Log & Report > Log Config > Log Settings** and select the checkbox next to **Disk**.
2. **Apply** the change.

To enable Disk Logging - CLI

```
config log disk setting
   set status enable
end
```

FortiView Feature Support - Platform Matrix

Note that the following table identifies three separate aspects of FortiView in FortiOS 5.2.3:

- Basic feature support
- Historical Data
- Disk Logging

Platform	Basic Feature Support	Disk Logging	Historical Data *
FG/FWF-20C Series	✔		
FG/FWF-30D/40C Series	✔		
FG/FWF-60C Series	✔		
FG/FWF-60D Series	✔		
FGR-60D	✔		
FG-60D	✔		
FG/FWF-80C Series	✔		
FG-80D	✔	✔	1 hour
FG/FWF-90D Series	✔	✔	1 hour
FG/FWF-92D Series	✔		
FG-110C	✔		
FG-111C	✔	**CLI**	1 hour
FG-100D Series	✔	✔	24 hours
FG-200B Series	✔	**#**	**#** (24 hours)
FG-200D Series	✔	✔	24 hours
FG-310B	✔		**#** (24 hours)
FG-311B	✔		**#** (24 hours)
FG-300C	✔	✔	24 hours
FG-300D	✔	✔	24 hours
FG-500D	✔	✔	24 hours
FG-620B	✔	**#**	**#** (24 hours)
FG-621B	✔	**#**	**#** (24 hours)
FG-600C	✔	✔	24 hours
FG-800C	✔	✔	24 hours

Platform	Basic Feature Support	Disk Logging	Historical Data *
FG-1000C	✔	✔	24 hours
FG-1500D	✔	✔	24 hours
FG-1240B	✔	✔	24 hours

FG-5001B	✔	**CLI**	24 hours
FG-5001C	✔	**CLI**	24 hours
FG-5001D	✔	**CLI**	24 hours
FG-5101C	✔	**CLI**	24 hours
FS-5203B	✔	**CLI**	

✔ = *Default support.*
= *Local storage required.*

* Refer to section on Historical Data below.

Basic feature support

FortiView's consoles give insight into your user's traffic, not merely showing which users are creating the most traffic, but what sort of traffic it is, when the traffic occurs, and what kind of threat the traffic may pose to the network.

FortiView basic feature support consists of the following consoles:

- Sources
- Applications
- Destinations
- All Sessions

The complete array of features in FortiView requires disk logging enabled (see below). It includes those consoles listed above as well as the following:

- Cloud Applications
- Web Sites
- Threats
- System Events
- Admin Logins
- VPN

Historical Data

Not all FortiView consoles have the same available historical data options, depending on whether or not your traffic is locally stored.

Below is a table showing which features are available for units using local storage, including the historical data options.

Only FortiGate models 100D and above support the 24 hour historical data.

Features	With Local Storage				Without Local Storage			
	Now	5 min	1 hr	24 hr *	Now	5 min	1 hr	24 hr
Sources	✔	✔	✔	✔	✔			
Applications	✔	✔	✔	✔	✔			
Cloud Applications	✔	✔	✔	✔	✔			
Destinations	✔	✔	✔	✔	✔			
Websites	✔	✔	✔	✔				
Threats		✔	✔	✔				
All Sessions	✔	✔	✔	✔	✔			
System Events		✔	✔	✔				
Admin Logins		✔	✔	✔				
VPN		✔	✔	✔				

* Not available for desktop models with SSD.

Disk Logging

Only certain FortiGate models support Disk Logging (see above).

To enable Disk Logging, go to **Log & Report > Log Config > Log Settings**, and select the checkbox next to **Disk** and apply the change.

Configuration Dependencies

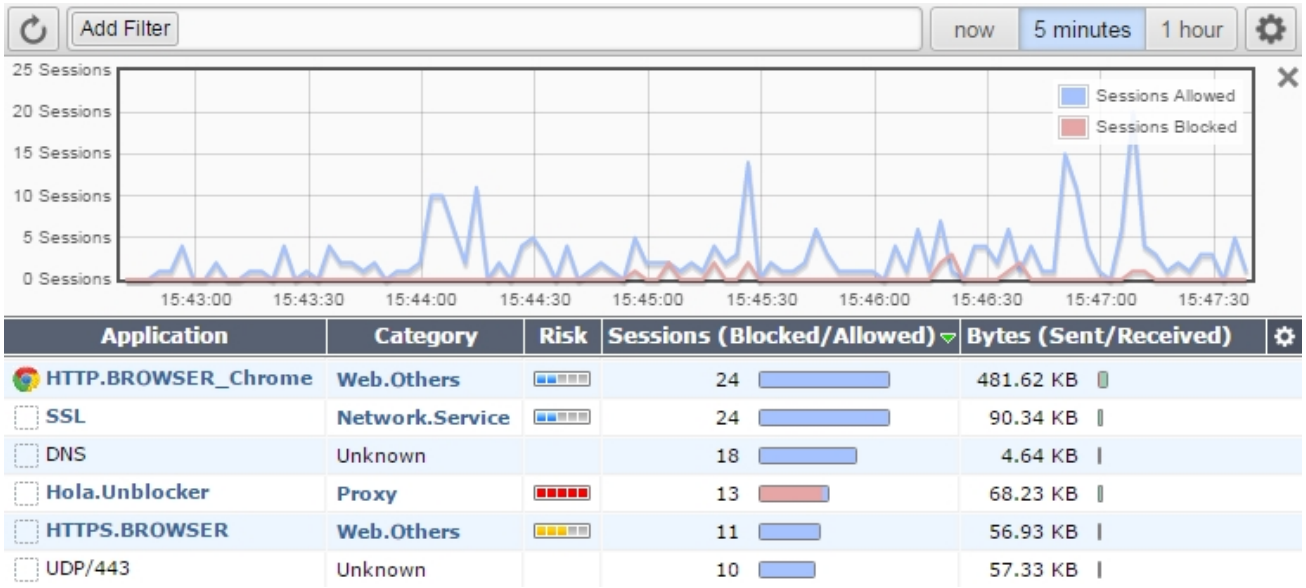
Most FortiView consoles require the user to enable several features to produce data. The following table summarizes the dependencies:

Feature	Dependencies (Realtime)	Dependencies (Historical)
Sources	None, always supported	Disk logging enabled Traffic logging enabled in policy
Applications	None, always supported	Disk logging enabled Traffic logging enabled in policy Application control enabled in policy
Cloud Applications	Not supported	Disk logging enabled Application control enabled in policy SSL "deep inspection" enabled in policy Deep application inspection enabled in application sensor Extended UTM log enabled in application sensor
Destinations	None, always supported	Disk logging enabled Traffic logging enabled in policy
Web Sites	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile	Disk logging enabled Web Filter enabled in policy "web-url-log" option enabled in Web Filter profile
Threats	Not supported	Disk logging enabled Traffic logging enabled in policy Threat weight detection enabled
All Sessions	None, always supported	Disk logging enabled Traffic logging enabled in policy
System Events	Not supported	
Admin Logins	Not supported	
VPN	Not supported	
FortiSandbox	Not supported	

FortiView interface

FortiView lets you access information about the traffic activity on your FortiGate, visually and textually. FortiView is broken up into several consoles, each of which features a top menu bar and a graph window, as seen in the following image:

FortiView Application console sorted by Sessions (Blocked/Allowed)



The top menu bar features a **Refresh** button, which updates the data displayed, a **Filter** button for filtering the data by category, **Time Display** options (now, 5 minutes, 1 hour, or 24 hours), and a **Settings** button (containing additional viewing settings and a link to the Threat Weight menu).

The graph window can be hidden using the **X** in the top right corner, and re-added by selecting **Show Graph**. To zoom in on a particular section of the graph, **click and drag** from one end of the desired section to the other. This will appear in the **Time Display** options as a **Custom** selection. The minimum selection size is 60 seconds.

Only FortiGate models 100D and above support the 24 hour historical data.

FortiView consoles

This section describes the following log filter consoles available in FortiView:

Sources

The **Sources** console provides information about the sources of traffic on your FortiGate unit. This console can be filtered by Destination Interface, Policy, Security Action, Source Device, Source Interface, and Source IP.

Specific devices and time periods can be selected and drilled down for deep inspection.

Scenario: Investigating a spike in traffic

A system administrator notices a spike in traffic and wants to investigate it. From the **Sources** window, they can determine which user is responsible for the spike by following these steps:

1. Go to **System > FortiView > Sources**.
2. In the graph display, click and drag across the peak that represents the spike in traffic.
3. Sort the sources by bandwidth use by selecting the **Bytes (Sent/Received)** header.
4. Drill down into whichever source is associated with the highest amount of bandwidth use by double-clicking it. From this screen, you have an overview of that source's traffic activity.
5. Again, in either the **Applications** or **Destinations** view, select the **Bytes (Sent/Received)** header to sort by bandwidth use.
6. Double-click the top entry to drill down to the final inspection level, from which you can access further details on the application or destination, and/or apply a filter to prohibit or limit access.

Only FortiGate models 100D and above support the 24 hour historical data.

Applications

The **Applications** console provides information about the applications being used on your network. This console can be filtered by Application, Destination Interface, Policy, Security Action, and Source Interface.

Specific devices and time periods can be selected and drilled down for deep inspection.

In order for information to appear in the **Applications** console, Application Control must be enabled in a policy.

Scenario: Viewing application usage

A manager is interested in the office internet habits of their employees:

1. Go to **System > FortiView > Applications**, to view the list of applications accessed by the users on your network. Use the time-frame options to view what applications were used in those time periods (from now, 5 minutes, 1 hour, or 24 hours).
2. From **Sessions (Blocked/Allowed)** and **Bytes (Sent/Received)**, you can see how much traffic has been generated. Click these columns to show the traffic in descending order.
3. You notice that a social media application has created the most traffic of all the applications, and so it's at the top of the list. Drill down into the application by double-clicking, or right-click and select **Drill down to details...**.
4. You are directed to a summary page of the social media application. From here, you can see which specific user has made the most use of the application.

Only FortiGate models 100D and above support the 24 hour historical data.

Cloud Applications

The **Cloud Applications** console provides information about the cloud applications being used on your network. This includes information such as:

- The names of videos viewed on YouTube (visible by hovering the cursor over the session entry)
- Filed uploaded and downloaded from cloud hosting services such as Dropbox
- Account names used for cloud services

Two different views are available for the Cloud Applications: **Applications** and **Users** (located in the top menu bar next to the time periods). **Applications** shows a list of the programs being used. **Users** shows information on the individual users of the cloud applications, including the username, if the FortiGate was able to view the login event.

This console can be filtered by Cloud Application.

In order for information to appear in the **Cloud Applications** console, an application control profile (that has Deep Inspection of Cloud Applications turned on) must be enabled in a policy, and SSL Inspection must use `deep-inspection`.

Scenario: Viewing cloud application usage data

From the Cloud Applications console, users can drill down to access detailed data on cloud application usage data. In this scenario, the console is used to determine the network's most frequent user of YouTube over a 24-hour period, and find out more about their usage patterns.

1. Go to **System > FortiView > Destinations**.
2. Select **Applications** view from the top menu bar if it is not already selected.
3. Select **24 Hours** from the Time Display options.
4. Find **YouTube** under the Application column and double-click it (or right-click and select **Drill down for details...**). This will open the YouTube stats window.

5. To determine the user who has accessed YouTube the most frequently, sort the column entries by **Sessions** by selecting the column header of the same name.
6. Double-click (or right-click and select **Drill down for details...**) the top-bandwidth YouTube user to view detailed stats, including the names of videos watched by the user and the date and time each video was accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Destinations

The **Destinations** console provides information about the destination IP addresses of traffic on your FortiGate unit, as well as the application used. You can drill down the displayed information, and also select the device and time period, and apply search filters.

This console can be filtered by Destination Interface, Destination IP, Policy, Security Action, and Source Interface.

Scenario: Monitoring destination data

The Destinations console can be used to access detailed information on user destination-accessing through the use of the console's drilldown functionality. In this scenario, the console is used to find out more about a particular user's Facebook usage patterns over a 24-hour period:

1. Go to **System > FortiView > Destinations**.
2. Select **1 hour** from the Time Display options at the top right corner of the console.
3. The easiest way to locate most destinations is to scan the Applications column for the name of the application. Once the session containing Facebook has been located, double-click it to access the Destination summary window.
4. Locate Facebook in the Applications column and double-click it to view the Facebook drilldown page. From here, detailed information regarding the user's Facebook session can be accessed.

Only FortiGate models 100D and above support the 24 hour historical data.

Web Sites

The **Web Sites** console lists the top allowed and top blocked web sites. You can view information by domain or by FortiGuard categories by using the options in the top right corner. Each FortiGuard category can be selected in order to see a description of the category and several example sites, with content loaded from FortiGuard on demand.

This dashboard can be filtered by Domain.

In order for information to appear in the **Web Sites** console, web filtering must be enabled in a policy, with FortiGate Categories enabled.

Scenario: Investigating an instance of Proxy Avoidance

In this scenario, the Categories view will be used to investigate an instance of Proxy Avoidance, one of the Categories recognized by FortiOS. Proxy Avoidance denotes the use of a proxy site in order to access data that might otherwise be blocked by the server.

1. Go to **System > FortiView > Web Sites** to open the Web Sites console.
2. Select **Categories** from the top bar menu to enter Categories view.
3. Scan the **Categories** column and locate the instance of Proxy Avoidance, then double-click it to enter its drill down screen.

Only FortiGate models 100D and above support the 24 hour historical data.

Threats

The **Threats** console lists the top users involved in incidents, as well as information on the top threats to your network.

The following incidents are considered threats:

- Risk applications detected by application control
- Intrusion incidents detected by IPS
- Malicious web sites detected by web filtering
- Malware/botnets detected by antivirus

The console can be filtered by Destination Interface, Policy, Security Action, Source Interface, Threat, and Threat Type.

In order for information to appear in the **Threats** console, Threat Weight Tracking must be enabled.

Scenario: Monitoring Threats to the Network

Some users have high Threat Scores. The Threats console can be used to view all threats and discover why such high scores are being shown:

1. In the graph display, click and drag across the peak that represents the spike in threat score.
2. Sort the threats by score or level by selecting the **Threat Score (Blocked/Allowed** or the **Threat Level** headers respectively.
3. You see that a specific threat's Threat Level is at Critical. Drill down into the threat by double-clicking, or right-click and select **Drill down to details...**.
4. From this summary page, you can view the source IPs and the number of sessions that came from this threat. Double-click on one of them.
5. The following page shows a variety of statistics, including **Reference**. The URL next to it will link you to a FortiGuard page where it will display the description, affected products, and recommended actions, if you are not familiar with the particular threat.

Only FortiGate models 100D and above support the 24 hour historical data.

All Sessions

The **All Sessions** console provides information about all FortiGate traffic. This console can be filtered by Application, Checksum, Destination Interface, Destination IP, Policy, Security Action, Source Device, Source Interface, Source IP, Threat, and Threat Type.

This console has the greatest number of column options to choose from. To choose which columns you wish to view, select the column settings cog at the far right of the columns and select your desired columns. They can then be clicked and dragged in the order that you wish them to appear.

A number of columns available in FortiView are only available in All Sessions. For example, the **Action** column displays the type of response taken to a security event. This function can be used to review what sort of threats were detected, whether the connection was reset due to the detection of a possible threat, and so on. This would be useful to display alongside other columns such as the **Source**, **Destination**, and **Bytes (Sent/Received)** columns, as patterns or inconsistencies can be analyzed.

Similarly, there are a number of filters that are only available in All Sessions, one of which is **Protocol**. This allows you to display the protocol type associated with the selected session, e.g. TCP, FTP, HTTP, HTTPS, and so on.

Scenario: Filtering sessions by port number and application type

From the **All Sessions** console, a wide variety of filters can be applied to sort the session data. In this example, the All Sessions filters will be used to locate a specific user's recent Skype activity.

1. Go to **System > FortiView > All Sessions**.
2. Select **now** from the **Time Display** options if it is not already selected.
3. Select the **Filter** button, then select **Applications**. This will open a drop-down menu listing the applications that appear in the master session list. From this list, locate and select **Skype**, or type `Skype` into the search bar and hit **Enter**. This will filter the session list to only feature Skype usage.
4. Select the **Filter** button again, then select **Destination Port** from the drop-down menu, then locate and select the desired port number. This will add a second filter which will restrict the results to presenting only the Skype data associated with that port number.

Only FortiGate models 100D and above support the 24 hour historical data.

System Events

The **System Events** console lists security events detected by FortiOS, providing a name and description for the events, an assessment of the event's severity level (**Alert**, **Critical**, **Emergency**, **Error**, or **Warning**), and the number of instances the events were detected. This console can be filtered by Event Name and Severity.

Scenario: Viewing Security Events & Security Actions

System Events can be used in conjunction with All Sessions to see what network security events took place, and specifically see what action was taken upon their detection:

- Go to **System > FortiView > System Events**, to see what and how many network events have taken place, as well as how severe they are in terms of the threat they pose to the network.
- You see that a particular event has warranted a severe rating, and has allowed traffic to bypass the firewall. Note when the event took place, and go to **System > FortiView > All Sessions**, to see more information pertaining to the security event.
- From this console, you can determine the system event's source, how much traffic was sent and received, and the security action taken in response to this security event. These actions differ, depending upon the severity of the security event. To view these actions, see the table-entry for **Security Action** in Columns displayed on page 1139.

Only FortiGate models 100D and above support the 24 hour historical data.

Admin Logins

The **Admin Logins** console provides information on administrator interactions with the network, including the number of login instances, number of failed logins, and the length of time logged in. This console can be filtered by User Name.

Scenario: Scrutinizing Administrator Security

Admin Logins can be used in conjunction with System Events to see who was on during a system change that impacted performance and allowed a threat to persist/pass through the firewall:

- Go to **System > FortiView > System Events**, to see what and how many network events have taken place, as well as how severe they are in terms of the threat they pose to the network.
- You see that a particular event has warranted a severe rating, and has allowed traffic to bypass the firewall. Double-click on the event to drill down.
- Once drilled down, you can see the date and time that the system change took place.
- Go to **System > FortiView > Admin Logins**, to see who has been logged in, how long they have been logged in, and what configuration changes they have made. Using the time graph, you can correlate the information from System Events with who was logged in at the time the threat was allowed.

Only FortiGate models 100D and above support the 24 hour historical data.

VPN

From the **VPN** console, users can access information on any VPNs associated with their FortiGate. From the initial window, a list of all the associated VPNs is provided, along with general information, such as number of user connections and VPN type. By double-clicking on an individual VPN (or right-clicking and selecting **Drill down for details...**), users can access more specific data on that VPN.

Logs in the VPN console can be sorted by number of connections, last connection time, or data sent/received by selecting the column headers.

This console can be filtered by User Name and VPN Type.

Certain dashboard options will not appear unless your FortiGate has Disk Logging enabled.

Furthermore, only certain FortiGate models support Disk Logging — refer to the FortiView Feature Support - Platform Matrix on page 1121 for more information.

To enable Disk Logging, go to **Log & Report > Log Config > Log Settings**, and select the checkbox next to **Disk** and apply the change.

Scenario: Investigating VPN user activity

The VPN console can be used to access detailed data on VPN-user activity via the use of the drill down windows. In this scenario, the administrator looks into the usage patterns of the IPsec user who has most frequently connected to the network.

1. Go to **System > FortiView > VPN** to view the VPN console.
2. Select the **Connections** column header to sort the entries by number of connections to the network.
3. Locate the top user whose VPN Type is **ipsec** and double-click the entry to enter that user's drill down screen.
4. To get the most representative data possible, sort the entries by bandwidth use by selecting the **Bytes (Sent/Received)** column header. Double-click the top entry to enter the drill down window for that connection instance.
   From this screen, the administrator can find out more about the specific session, including the date/time of access, the XAuth (Extensible Authentication) User ID, the session's Tunnel ID, and more.

Reference

This section consists of reference information for the various consoles in FortiView. Each console has an assortment of filtering options, drilldown options, and columns that can be displayed. Since many of these options and columns persist through each console, the entire list of options and their descriptions is included below. Attempts have been made to identify the instances where an option or column is only available to a particular console.

This section includes:

Filtering options

When you select the **Add Filter** button, a drop-down list appears with a list of available filtering options. Available options differ based on which console is currently being viewed. The following table explains all of the available filtering options:

Filter option	Description
Application	Filter by application name.
Checksum	Filter by checksum value. Checksums are reference digits used to represent the correct datasum of a packet in order to detect errors.
Cloud Application	Filter by cloud application name. **Note:** This filter is only available in the **Cloud Applications** console.
Destination Interface	Filter by the interface type used by the destination user, e.g. wan1.
Destination IP	Filter by the IP address used by the destination.
Destination Port	Filter by the port used by the destination. **Note:** This filter is only available in the **All Sessions** console,(viewing the **now** time display).
Domain	Filter by domain name. **Note:** This filter is only available in the **Web Sites** console.
Event Name	Filter by security event name. **Note:** This filter is only available in the **System Events** console.
File Name	Filter by file name. **Note:** This filter is only available in the **FortiSandbox** console.
NAT Source IP	Filter by the NAT-translated source IP address. **Note:** This filter is only available in the **All Sessions** console,(viewing the **now** time display).
NAT Source Port	Filter by the NAT-translated source interface. **Note:** This filter is only available in the **All Sessions** console,(viewing the **now** time display).
Policy	Filter by the policy identification number.
Protocol	Filter by the protocol used by the source, e.g. tcp or udp. **Note:** This filter is only available in the **All Sessions** console,(viewing the **now** time display).

Filter option	Description
Security Action	Filter by the type of response taken to the security event. The types of possible actions are as follows: **Allowed:** No threat was detected and the connection was let through. **Blocked:** A threat was detected and the connection was not let through. **Reset:** A possible issue was detected and the connection was reset. **Traffic Shape:** Some data packets may have been delayed to improve system-wide performance.
Severity	Filter by the severity level (**Critical**, **High**, **Medium** or **Low**) associated with a security event.
Source Device	Filter by source device type, e.g. mobile.
Source Interface	Filer by the interface type used by the source user, e.g. wan1.
Source IP	Filter by the source IP address.
Source Port	Filter by the source interface. **Note:** This filter is only available in the **All Sessions** console,(viewing the **now** time display).
Status	Filter by the maliciousness of a file. The types of possible status' are **Malicious**, **High**, **Medium**, **Low**, **Clean**, **Unknown**, and **Pending**. **Note:** This filter is only available in the **FortiSandbox** console.
Threat	Filter by threats received.
Threat Type	Filter by threat classification, e.g. DoS.
User Name	Filter by user name.
VPN Type	Filter by Virtual Private Network (VPN) protocol type, e.g. PPTP. **Note:** This filter is only available in the **VPN** console.

Drilldown options

Double-click, or right-click, on any entry in a FortiView console and select **Drill down to details...**, to view the following tabs (options vary depending on the console selected):

Drilldown option	Description
Applications	Select to drill down by application to view application-related information, including the application name, sessions blocked and allowed, bytes sent and received, and the risk level. You can sort entries by selecting the column header.
Destinations	Select to drill down by destination to view destination-related information, including the IP address and geographic region, interface, threat score, number of sessions blocked and allowed, and bytes sent and received. You can sort entries by selecting the column header.
Threats	Select to drill down by threat to view threat-related information, including the threat name, category, threat level, threat score, and number of sessions blocked and allowed. You can sort entries by selecting the column header.
Domains	Select to drill down by domain to view domain-related information, including domain name, category, browsing time, threat weight, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Categories	Select to drill down by category to view category-related information, including category name, browsing time, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.
Sessions	Select to drill down by sessions to view session-related information, including date/time, source, destination IP address and geographic region, application name,security action, security event, and bytes sent/received. You can sort entries by selecting the column header.
Sources	Select to drill down by rows to view source-related information, including IP address, device type, interface type, threat score, number of sessions blocked/allowed, and bytes sent/received. You can sort entries by selecting the column header.

Columns displayed

The following columns appear in the initial window of the consoles. Some columns may only be visible by selecting them from the column drop-down menu. Options also vary depending on the console selected.

Column name	Description
Action	Displays the type of response taken to a security event. The types of possible actions are as follows: • **Allowed**: No threat was detected and the connection was let through. • **Blocked**: A threat was detected and the connection was not let through. • **Reset**: A possible issue was detected and the connection was reset. • **Traffic Shape**: Some data packets may have been delayed to improve system-wide performance. **Note:** This column is only available in the **All Sessions** console.
Application	Displays the application name and service. When **Time Display** is set to **now**, you can access further information about an application by selecting the column entry.
Application Category	Displays the type of application used in the selected session, e.g. video player, social media. **Note:** This column is only available in the **All Sessions** console.
Application ID	Displays the identification number associated with the application used in the selected session. **Note:**This column is only available in the **All Sessions** console.
Application Risk **Risk**	Displays the application risk level. You can hover the mouse cursor over the entry in the column for additional information, and select the column header to sort entries by level of risk. Risk uses a 5-point risk rating. The rating system is as follows: • **Critical**: Applications that are used to conceal activity to evade detection. • **High**: Applications that can cause data leakage, are prone to vulnerabilities, or may download malware. • **Medium**: Applications that can be misused. • **Elevated**: Applications that are used for personal communications or can lower productivity. • **Low**: Business-related applications or other harmless applications.

Column name	Description
Browsing Time	Displays the amount of time a user has spent browsing a web site (in seconds). **Note:** This column is only available in the **Web Sites** console, in **Categories** view..
Bytes (Sent/Received)	Displays the size of sent and received data packets, as measured in bytes. Select the column header to sort the entries by size. **Note:** This information is available on some consoles as two separate columns: **Sent** and **Received**.
Category	Displays the category descriptor appropriate to whatever console is being displayed. For example, threat categories are displayed in the Threats console.
Clean	Displays the number of "clean" (safe) files found in the selected FortiSandbox session. **Note:** This column is only available in the **FortiSandbox** console, in **Source** view.
Cloud User	Displays the users accessing cloud applications by IP address. **Note:** This column is only available in the **Cloud Applications** console, in **Users** view.
Configuration Changes	Displays the number of configuration changes made by the user. You can hover the mouse cursor over an entry for additional information. **Note:** This column is only available in the **Admin Logins** console.
Connections	Displays the number of VPN connections made by the selected user.. **Note:** This column is only available in the **VPN** console.
Destination	Displays the destination name, IP address and geographic region.
Destination Country	Displays the country session data is being sent to. **Note:** This column is only available in the **All Sessions** console.
Destination Interface	Displays which interface session data is being sent through, e.g. wan1.
Destination Port	Displays the port number of the destination server being used to accept data. Note: This column is only available in the **All Sessions** console.

Column name	Description
Device	Displays the device IP address or Fully Qualified Domain Name (FQDN).
Domain	Displays the domain associated with the selected web site, e.g. google.-com. **Note:** This column is only available in the **Web Sites** console.
DST Nat IP **NAT Destination**	Displays the Network Address Translation (NAT) IP address associated with the destination server. **Note:** This column is only available in the **All Sessions** console.
DST Nat Port **NAT Destination Port**	Displays the Network Address Translation (NAT) port number associated with the destination server. **Note:** This column is only available in the **All Sessions** console.
Duration	Displays the amount of time (in seconds) a user has been logged in. **Note:** This column is only available in the **Admin Logins** console.
Event Name (Description)	Displays the name and description of the selected security event. **Note:** This column is only available in the **System Events** console.
Events	Displays the number of security events that occurred within a selected session. **Note**: This column is only available in the **System Events** console.
Expires	Displays the amount of time a session has (in seconds) before it is set to expire. **Note:** This column is only available in the **All Sessions** console, in **now** Time Display view.
Failed Logins	Displays the number of failed login attempts made by an administrator over the specified time period. **Note:** This column is only available in the **Admin Logins** console.
Files (Up/Down)	Displays the number of files uploaded and downloaded. Hover the mouse cursor over the entry in the column for additional information. **Note:** This column is only available in the **Cloud Applications** console.

Column name	Description
FortiASIC	Displays the type of FortiASIC hardware acceleration used in the specified session, if present. **Note:** This column is only available in the **All Sessions** console, in the **now** Time Display view.
Group	Displays the group ID associated with the selected session. **Note:** This column is only available in the **All Sessions** console.
Last Connection Time	Displays the most recent instance of connection to the selected Virtual Private Network (VPN). **Note:** This column is only available in the **VPN** console.
Level **Threat Level**	Displays the threat level. Select the column header to sort entries by threat level.
Log ID	Displays the identification number for the data log associated with this entry. **Note:** This column is only available in the **All Sessions** console.
Login IDs	Displays the number of login IDs associated with the selected cloud application. **Note:** This column is only available in the **Cloud Applications** console, in **Applications** view.
Logins	Displays the number of successful logins made by an administrator over the specified time period. **Note:** This column is only available in the **Admin Logins** console.
Policy ID	Displays the identification number of the policy under which the selected connection was allowed.
Policy UUID	Displays the Universally Unique Identifier (UUID) of the selected policy, if present. **Note:** This column is only available in the **All Sessions** console.
Protocol	Displays the protocol type associated with the selected session, e.g. TCP. **Note:** This column is only available in the **All Sessions** console.

Column name	Description
Security Action	Displays the action taken in response to the selected security event. The types of possible actions are as follows: • **Allowed**: No threat was detected and the connection was let through. • **Blocked**: A threat was detected and the connection was not let through. • **Reset**: A possible issue was detected and the connection was reset. • **Traffic Shape**: Some data packets may have been delayed to improve system-wide performance.
Security Events	Displays the type of security event detected in the selected session. **Note**: This column only appears in the **All Sessions** console.
Sequence Number	Displays the TCP sequence number associated with the selected session. **Note**: This column only appears in the **All Sessions** console.
Service	Displays the ID of the service application in use in the selected session. **Note:** This column only appears in the **All Sessions** console.
Sessions	Displays the number of sessions associated with the selected destination. **Note:** This column only appears in the **Destinations** console, in the **now** Time Display view.
Sessions (Blocked/Allowed)	Displays the number of sessions blocked and allowed by FortiOs. In some consoles, entries can be sorted by number of sessions by selecting the column header..
Severity	Displays the severity level (**Critical**, **High**, **Medium** or **Low**) associated with the selected security event. **Note:** This column is only available in the **System Events** console.
Source	Displays the source IP address and/or user ID, if applicable.
Source Interface	Displays which interface is being used by the destination server (eg. wan1).
Source Port	Displays the port number being used by the source server to send data.
Src NAT IP **NAT Source**	Displays the Network Address Translation (NAT) IP address associated with the source server.

Column name	Description
Src NAT Port **NAT Source Port**	Displays the Network Address Translation (NAT) port number associated with the source server.
Status	Displays the status of **Note:** This column is only available in the **FortiSandbox** console, in **Files** view.
Submittted	Displays the number of files submitted to the FortiSandbox for assessment in the selected session. **Note:** This column is only available in the **FortiSandbox** console, in **Files** view.
Threat	Displays the threat type detected in the selected session.
Threat Score (Blocked/Allowed)	Displays the threat score value, a measurement of the total number of threats detected over the course of the session. You can select the column header to sort entries by threat score.
Threat Weight	Displays the threat weight profile associated with the selected session.
Timestamp	Displays the selected session's PHP timestamp.
User **User Name**	Displays the user name associated with the selected administrator.
Videos Played	Displays the number of videos played via cloud applications. **Note:** This column is only available in the **Cloud Applications** console.
VPN	Displays the Virtual Private Networks (VPNs) connected to the FortiGate, by name. **Note:** This column is only available in the **All Sessions** console.
VPN Type	Displays the type of VPN protocol (eg. PPTP, L2TP) in use by the associated connection.

Risk level indicators

There are currently two consoles within FortiView that display the Risk associated with the console: Applications and Cloud Applications. Each application pose different levels of risk to the network, represented by a colour code.

The following table identifies each risk level, from least to most severe:

Indicator	Risk	Description
	Green: *Risk Level 1*	These applications have little to no risk level, with no assigned risk definition. Application file-sharing may result in data leakage, which would be a typical example of a low level risk. An example application would be the Google toolbar, or Dropbox.
	Blue: *Risk Level 2*	These applications have an elevated risk level and typically use excessive bandwidth. High bandwidth consumption can lead to increased operational costs. An example application would be Bittorrent.
	Yellow: *Risk Level 3*	These applications have a low risk level and are typically evasive. Evasive applications can lead to compliance risks, and could include applications such as JustinTV and GlypeProxy.
	Orange: *Risk Level 4*	These applications have a high risk level, and are defined as using both excessive and evasive bandwidth. Example applications would be AutoHideIP and PandoraTV.
	Red: *Risk Level 5*	Applications that have a high risk level are prone to malware or vulnerabilities that can introduce business continuity risks.

Troubleshooting FortiView

FortiView does not display all consoles listed in this document

Some consoles require disk logging to be enabled before they will appear in FortiView. These include:

- Admin Logins
- Cloud Applications
- FortiSandbox
- Sources
- System Events
- Threats
- VPN
- Web Sites

Only certain FortiGate models support Disk Logging — refer to the FortiView Feature Support - Platform Matrix on page 1121 for more information.

No logging data is displayed

In order for information to appear in the FortiView consoles, disk logging must be selected for the FortiGate unit. To select disk logging, go to **Log & Report > Log Config > Log Settings**.

Disk logging is disabled by default for some FortiGate units. To enable disk logging, enter the following command in the CLI:

```
config log disk setting
   set status enable
end
```

Only certain FortiGate models support Disk Logging — refer to the FortiView Feature Support - Platform Matrix on page 1121 for more information.

Chapter 11 - Hardening

Hardening your FortiGate

This document describes a series of techniques used to improve the security of administrative access to a FortiGate device.

The following sections are included:

Install the FortiGate unit in a physically secure location
Maintain the firmware
Add new administrator accounts
Change the admin account name and limit access to this account
Only allow administrative access to the external interface when needed
When enabling remote access, configure Trusted Hosts and Two-factor Authentication
Change the default administrative port to a non-standard port
Modify the device name
Register with support services
Maintain short login timeouts
Enable automatic clock synchronization
Enable Password Policy
Modify administrator account Lockout Duration and Threshold values
Disable auto installation via USB
Configure auditing and logging

Install the FortiGate unit in a physically secure location

A good place to start with is physical security. Install the FortiGate unit in a secure location, such as a locked room or a room with restricted access. This way unauthorized users can't get physical access to the device.

If unauthorized users have physical access they can disrupt your entire network by disconnecting your FortiGate unit (either by accident or on purpose). They could also connect a console cable and attempt to log into the CLI. Also, when a FortiGate unit reboots, a person with physical access can interrupt the boot process and install different firmware.

Maintain the firmware

On installation of a new firewall, it is necessary to update the firmware to the latest version provided by the manufacturer.

Fortinet periodically updates the FortiGate firmware to include new features and resolve important issues. After you have registered your FortiGate unit, you can download firmware updates from the support web site, https://support.fortinet.com.

Before you install any new firmware, be sure to follow the steps below:

- Review the Release Notes for a new firmware release.
- Review the Supported Upgrade Paths document to make sure the upgrade from your current image to the desired new image is supported.
- Backup the current configuration, including local certificates.
- Test the new firmware until you are satisfied that it applies to your configuration.

Installing new firmware without reviewing release notes or testing the firmware may result in changes to settings or unexpected issues.

Only FortiGate admin users and administrators whose access profiles contain system read and write privileges can change the FortiGate firmware.

Add new administrator accounts

Rather than allowing all administrators to access the FortiGate unit with the admin administrator account you should create administrator accounts for each person that requires administrative access. That way you can track who has made configuration changes and performed other administrative activities. Keep the number of administrative accounts to a minimum to keep better control on who can access the device.

To add administrators go to **System > Admin > Administrators** and select **Create New**.

If you want administrators to have access to all FortiGate configuration options, their accounts should have the **prof_admin** admin profile. Administrators with this profile can do anything except add new administrator accounts.

At least one account should always have the **super_admin** profile as this profile is required to add and remove administrators. To improve security only a very few administrators (usually one) should be able to add new administrators.

If you want some administrator accounts to have limited access to the FortiGate configuration you can create custom admin profiles that only allow access to selected parts of the configuration. To add custom admin profiles, go to **System > Admin > Admin Profiles** and select **Create New**.

For example, if you want to add an admin profile that does not allow changing firewall policies, when you configure the admin profile set **Firewall Configuration** to **None** or **Read Only**.

Change the admin account name and limit access to this account

The default super_admin administrator account, admin, is a well known administrator name so if this account is available it could be easier for attackers to access the FortiGate unit because they know they can log in with this name, only having to determine the password. You can improve security by changing this name to one more difficult for an attacker to guess.

To do this, create a new administrator account with the super_admin admin profile and log in as that administrator. Then go to **System > Admin > Administrators** and edit the admin administrator and change the Administrator name.

Once the account has been renamed you could delete the super_admin account that you just added. Consider also only using the super-admin account for adding or changing administrators. The less this account is used to less likely that it could be compromised. You could also store the account name and password for this account in a secure location in case for some reason the account name or password is forgotten.

Only allow administrative access to the external interface when needed

When possible, don't allow administration access on the external interface and use internal access methods such as IPsec VPN or SSL VPN.

To disable administrative access on the external interface, go to **System > Network > Interfaces,** edit the external interface and disable HTTPS, PING, HTTP, SSH, and TELNET under **Administrative Access.**

This can also be done with CLI using following commands:

```
config system interface
   edit <external_interface_name>
   unset allowaccess
end
```

Please note that this will disable all services on the external interface including CAPWAP, FMG-Access, SNMP, and FCT-Access. If you need some of these services enabled on your external interface, for example CAPWAP and FMG-Access to ensure connectivity between FortiGate unit and respectively FortiAP and FortiManager, then you need to use following CLI command:

```
config system interface
   edit <external_interface_name>
   set allowaccess capwap fgfm
end
```

When enabling remote access, configure Trusted Hosts and Two-factor Authentication

If you have to have remote access and can't use IPsec or SSL VPN then you should only allow HTTPS and SSH and use secure access methods such as trusted hosts and Two-factor authentication.

Configuring Trusted Hosts

Setting trusted hosts for administrators limits what computers an administrator can log in the FortiGate unit from. When you identify a trusted host, the FortiGate unit will only accept the administrator's login from the configured IP address or subnet. Any attempt to log in with the same credentials from any other IP address or any other subnet will be dropped. To ensure the administrator has access from different locations, you can enter up to ten IP addresses or subnets. Ideally, this should be kept to a minimum. For higher security, use an IP address with a net mask of 255.255.255.255, and enter an IP address (non-zero) in each of the three default trusted host fields.

Trusted hosts are configured when adding a new administrator by going to **System > Admin > Administrators** in the web-based manager and selecting **Restrict this Admin Login from Trusted Hosts Only**, or `config system admin` in the CLI.

The trusted hosts apply to the web-based manager, ping, snmp and the CLI when accessed through SSH. CLI access through the console port is not affected.

Also ensure all entries contain actual IP addresses, not the default 0.0.0.0.

Configuring Two-factor Authentication

FortiOS 5.0 provides support for FortiToken and FortiToken Mobile. FortiToken Mobile is a Fortinet application that enables you to generate One Time Passwords (OTPs) on a mobile device for FortiGate two-factor authentication. The user's mobile device and the FortiGate unit must be connected to the Internet to activate FortiToken mobile. Once activated, users can generate OTPs on their mobile device without having network

access. FortiToken Mobile is available for iOS and Android devices from their respective Application stores. No cellular network is required for activation.

The latest FortiToken Mobile documentation is available from the FortiToken page of the Fortinet Technical Documentation website.

Two free trial tokens are included with every registered FortiGate unit. Additional tokens can be purchased from your reseller or from Fortinet.

To assign a token to an administrator go to **System > Admin > Administrators** and either add a new or select an existing administrator to assign the token to. Configure the administrator as required, you need to enter your email address and phone number in order to receive the activation code for the FortiToken mobile. Select **Enable Two-factor Authentication**. Select the token to associate with the administrator. Select **OK** to assign the token to the administrator.

To configure your FortiGate unit to send email or SMS messages go to **System > Config > Advanced > Email Service** or **System > Config > Advanced > SMS Service**.

Change the default administrative port to a non-standard port

Administration Settings under **System > Admin > Settings** or `config system global` in the CLI, enable you to change the default port configurations for administrative connections to the FortiGate unit for added security. When connecting to the FortiGate unit when the port has changed, the port must be included. For example, if you are connecting to the FortiGate unit using HTTPS over port 8081, the URL would be `https://192.168.1.99:8081`

If you make a change to the default port number for HTTP, HTTPS, Telnet, or SSH, ensure that the port number is not used for other services.

Modify the device name

The name of the device needs to be modified in order for it to be perfectly identified. A label shall also be placed with the device name. Finally it shall be necessary to add an entry in the DNS with the name of the unit and its IP address.

Register with support services

In order to activate the services and warranty of the device, it is necessary to register the serial number of the device in the manufacturer's website. This task shall always be performed with the same account under which all units have been registered, in order to obtain centralized management.

Maintain short login timeouts

To avoid the possibility of an administrator walking away from the management computer and leaving it exposed to unauthorized personnel, you can add an idle time-out. That is, if the web-based manager is not used for a specified amount of time, the FortiGate unit will automatically log the administrator out. To continue their work, they must log in again.

The time-out can be set as high as 480 minutes, or eight hours, although this is not recommend.

To set the idle time out, go to **System > Admin > Settings** and enter the amount of time for the Idle Timeout. A best practice is to keep the default of 5 min.

When logging into the console using SSH, the default time of inactivity to successfully log into the FortiGate unit is 120 seconds (2 minutes). You can configure the time to be shorter by using the CLI to change the length of time the command prompt remains idle before the FortiGate unit will log the administrator out. The range can be between 10 and 3600 seconds. To set the logout time enter the following CLI commands:

```
config system global
   set admin-ssh-grace-time <number_of_seconds>
end
```

Enable automatic clock synchronization

Maintain the clock in the device synchronized with the rest of the devices in the network. This facilitates auditing and consistency between expiry dates used in expiration of certificates and security protocols.

In Global configuration mode (`Config Global`), execute:

```
config system ntp
      config ntpserver
         edit 1
            set server "192.0.2.1"
         next
      end
   set ntpsync enable
   set syncinterval 60
end
```

Enable Password Policy

Brute force password software can launch more than just dictionary attacks. It can discover common passwords where a letter is replaced by a number. For example, if “p4ssw0rd” is used as a password, it can be cracked.

Password policies, available by going to **System > Admin > Settings > Enable Password Policy**, enable you to create a password policy that any administrator who updates their passwords, must follow. Using the available options you can define the required length of the password, what it must contain (numbers, upper and lower case, and so on) and an expiry time frame. The FortiGate unit will warn of any password that is added and does not meet the criteria.

Modify administrator account Lockout Duration and Threshold values

Account lockout policies control how and when accounts are locked out of the FortiGate unit. These policies are described and implemented as follows:

Administrator account Lockout Duration

If someone violates the lockout controls by entering an incorrect user name and/or password, account lockout duration sets the length of time the account is locked. the lockout duration can be set to a specific length of time using a value between 1 and 4294967295 seconds. The default value is 60 seconds.

When it’s required use the CLI to modify the lockout duration as follow:

```
config system global
   set admin-lockout-duration <integer>
end
```

Administrator account Lockout Threshold

The lockout threshold sets the number of invalid logon attempts that are allowed before an account is locked out. You may set a value that balances the need to prevent account cracking against the needs of an administrator who may have difficulty accessing their account.

Its normal for an administrator to sometimes take a few attempts to logon with the right password.

The lockout threshold can be set to any value from 1 to 10. The Default value is 3, which is normally a good setting. However, to improve security you could reduce it to 1 or 2 as long as administrators know to take extra care when entering their passwords.

Use the following CLI command to modify the lockout threshold:

```
config system global
   set admin-lockout-threshold <integer>
end
```

Keep in mind that the higher the lockout value, the higher the risk that someone may be able to break into the FortiGate unit.

Disable auto installation via USB

An attacker with a physical access to the device could load a new configuration or firmware on the FortiGate using the USB port, reinitializing the device through a power cut. To avoid this, execute the following CLI commands:

```
config system auto-install
   set auto-install-config disable
   set auto-install-image disable
end
```

Configure auditing and logging

Audit web facing administration interfaces. By default, FortiGate logs all deny actions. You can check these actions by going to **Log & Report > Event Log > System**. This default behavior should not be changed. Also secure log files in a central location such as FortiCloud and configure alert email which provides an efficient and direct method of notifying an administrator of events. You can configure log settings by going to **Log & Report** > **Log Config**.

An auditing schedule should be established to routinely inspect logs for signs of intrusion and probing.

Chapter 12 - Hardware Acceleration

This FortiOS Handbook chapter contains the following sections:

Hardware acceleration overview describes the capabilities of FortiGate content processors (CPs), security processors (SPs) and network processors (NPs). This chapter also describes how to determine the hardware acceleration components installed in your FortiGate unit and contains some configuration details and examples.

NP6 Acceleration describes the FortiGate NP6 network processor.

FortiGate NP6 architectures contains details about the network processing architectures of FortiGate units that contain NP6 processors.

NP4 Acceleration describes the FortiGate NP4 network processor.

FortiGate NP4 architectures contains details about the network processing architectures of FortiGate units that contain NP4 processors.

Hardware acceleration overview

Most FortiGate models have specialized acceleration hardware that can offload resource intensive processing from main processing (CPU) resources. Most FortiGate units include specialized content processors (CPs) that accelerate a wide range of important security processes such as virus scanning, attack detection, encryption and decryption. (Only selected entry-level FortiGate models do not include a CP processor.) Many FortiGate models also contain security processors (SPs) that accelerate processing for specific security features such as IPS and network processors (NPs) that offload processing of high volume network traffic.

Content processors (CP4, CP5, CP6 and CP8)

Most FortiGate models contain FortiASIC Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

CP8 capabilities

The CP8 content processor provides the following services:

- IPS signature matching acceleration
- High performance VPN bulk data engine
  - IPsec and SSL/TLS protocol processor
  - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
  - ARC4 in compliance with RC4
  - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primarily checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - Random Number generator compliance with ANSI X9.31
  - Sub public key engine (PKCE) to support up to 4096 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

CP6 capabilities

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor

- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

CP5 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPSEC Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

CP4 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC
- IPSEC protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
get hardware status
Model name: FortiGate-100D
ASIC version: CP8
ASIC SRAM: 64M
CPU: Intel(R) Atom(TM) CPU D525 @ 1.80GHz
Number of CPUs: 4
RAM: 1977 MB
Compact Flash: 15331 MB /dev/sda
Hard disk: 15272 MB /dev/sda
USB Flash: not available
Network Card chipset: Intel(R) PRO/1000 Network Connection (rev.0000)
Network Card chipset: bcm-sw Ethernet driver 1.0 (rev.)
```

The ASIC version line lists the content processor model number.

Viewing SSL acceleration status

You can view the status of SSL acceleration using the following command:

```
get vpn status ssl hw-acceleration-status
Acceleration hardware detected: kxp=on cipher=on
```

Disabling CP offloading for firewall policies

If you want to completely disable offloading to CP processors for test purposes or other reasons, you can do so in security policies. Here are some examples:

For IPv4 security policies.

```
config firewall policy
   edit 1
      set auto-asic-offload disable
   end
```

For IPv6 security policies.

```
config firewall policy6
   edit 1
      set auto-asic-offload disable
   end
```

For multicast security policies.

```
config firewall multicast-policy
   edit 1
      set auto-asic-offload disable
   end
```

Disabling `auto-asic-offload` also disables NP offloading.

Security processors (SPs)

FortiGate Security Processing (SP) modules, such as the SP3 but also including the XLP, XG2, XE2, FE8, and CE4, work at both the interface and system level to increase overall system performance by accelerating specialized security processing. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments.

SP processors include their own IPS engine which is similar to the FortiOS IPS engine but with the following limitations:

- The SP IPS engine does not support SSL deep inspection. When you have SSL deep inspection enabled for a security policy that includes flow-based inspection or IPS, offloading to the SP is disabled and traffic is processed by the FortiGate CPU and CP processors.
- The SP IPS engine does not support FortiGuard Web Filtering. When you enable flow-based FortiGuard Web Filtering on a FortiGate unit with an SP processor, the SP processor cannot perform FortiGuard lookups and web pages fail to load.

The following security processors are available:

- The SP3 (XLP) is built into the FortiGate-5101B and provides IPS acceleration. No special configuration is required. All IPS processing, including traffic accepted by IPv4 and IPv6 traffic policies and IPv4 and IPv6 DoS policies is accelerated by the built-in SP3 processors.
- The FMC-XG2 is an FMC module with two 10Gb/s SPF+ interfaces that can be used on FortiGate-3950B and FortiGate-3951B units.
- The FortiGate-3140B also contains a built-in XG2 using ports 19 and 20.

- The ADM-XE2 is a dual-width AMC module with two 10Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.
- The ADM-FE8 is a dual-width AMC module with eight 1Gb/s interfaces that can be used with the FortiGate-3810A.
- The ASM-CE4 is a single-width AMC module with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an SP processor.If you disable SP offloading traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for individual policies. You can also use the following command to disable all IPS offloading

```
config ips global
   set np-accel-mode none
   set cp-accel-mode none
end
```

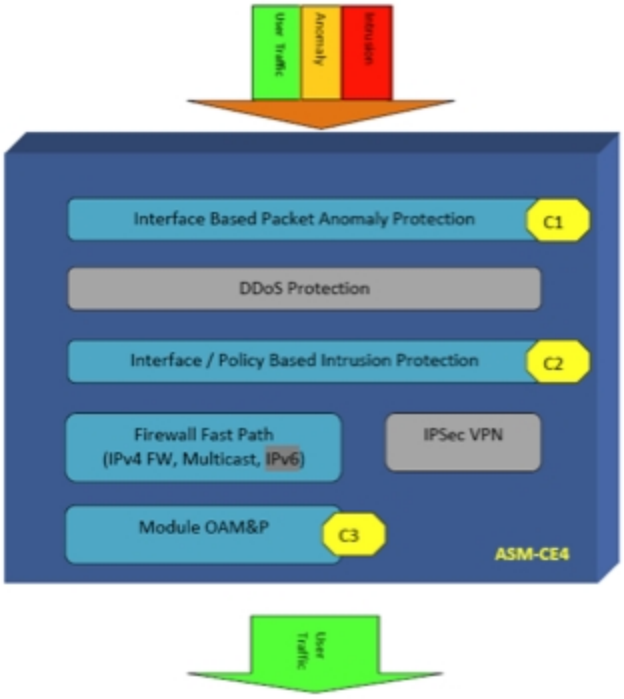
SP Processing Flow

SP processors provide an integrated high performance fast path multilayer solution for both intrusion protection and firewall functions. The multilayered protection starts from anomaly checking at packet level to ensure each packet is sound and reasonable. Immediately after that, a sophisticated set of interface based packet anomaly protection, DDoS protection, policy based intrusion protection, firewall fast path, and behavior based methods are employed to prevent DDoS attacks from the rest of system.

Then the packets enter an interface/policy based intrusion protection system,

where each packet is evaluated against a set of signatures. The end result is streams of user packets that are free of anomaly and attacks, entering the fast path system for unicast or multicast fast path forwarding.

SP processing flow



Displaying information about security processing modules

You can display information about installed SP modules using the CLI command

```
diagnose npu spm
```

For example, for the FortiGate-5101C:

```
FG-5101C # diagnose npu spm list
Available SP Modules:

ID Model      Slot     Interface
0 xh0         built-in  port1, port2, port3, port4,
                        base1, base2, fabric1, fabric2
                        eth10, eth11, eth12, eth13
                        eth14, eth15, eth16, eth17
                        eth18, eth19
```

You can also use this command to get more info about SP processing. This example shows how to display details about how the module is processing sessions using the syn proxy.

```
diagnose npu spm dos synproxy <sp_id>
```

This is a partial output of the command:

```
Number of proxied TCP connections :                 0
Number of working proxied TCP connections :         0
Number of retired TCP connections :                 0
Number of valid TCP connections :                   0
Number of attacks, no ACK from client :             0
Number of no SYN-ACK from server :                  0
Number of reset by server (service not supportted): 0
Number of estabilised session timeout :             0
```

```
Client timeout setting :                          3 Seconds
Server timeout setting :                          3 Seconds
```

Network processors (NP1, NP2, NP3, NP4 and NP6)

FortiASIC network processors work at the interface level to accelerate traffic by offloading traffic from the main CPU. Current models contain NP4 and NP6 network processors. Older FortiGate models include NP1 network processors (also known as FortiAccel, or FA2) and NP2 network processors.

The traffic that can be offloaded, maximum throughput, and number of network interfaces supported by each varies by processor model:

- NP6 supports offloading of most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a capacity of 40 Gbps through 4 x 10 Gbps interfaces or 3 x 10 Gbps and 16 x 1 Gbps interfaces. For details about the NP6 processor, see NP6 Acceleration on page 1170 and for information about FortiGate models with NP6 processors, see FortiGate NP6 architectures on page 1185.
- NP4 supports offloading of most IPv4 firewall traffic and IPsec VPN encryption. The NP4 has a capacity of 20 Gbps through 2 x 10 Gbps interfaces. For details about NP4 processors, see NP4 Acceleration on page 1222 and for information about FortiGate models with NP4 processors, see FortiGate NP4 architectures on page 1237.
- NP2 supports IPv4 firewall and IPsec VPN acceleration. The NP2 has a capacity of 2 Gbps through 2 x 10 Gbps interfaces or 4 x 1 Gbps interfaces.
- NP1 supports IPv4 firewall and IPsec VPN acceleration with 2 Gbps capacity. The NP1 has a capacity of 2 Gbps through 2 x 1 Gbps interfaces.
  - The NP1 does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1 ports. Maximum frame size for NP2, NP4, and NP6 processors is 9216 bytes.
  - For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Sessions that require proxy-based and flow based security features (for example, virus scanning, IPS, application control and so on) are not fast pathed and must be processed by the CPU

Determining the network processors installed on your FortiGate unit

Use the following command to list the NP6 processors in your FortiGate unit:

```
diagnose npu np6 port-list
```

To list other network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
```

`<model>` can be `legacy`, `np1`, `np2` or `np4`.

The output lists the interfaces that have the specified processor. For example, for a FortiGate-5001B:

```
get hardware npu np4 list
ID    Model          Slot       Interface
0     On-board                  port1 port2 port3 port4
                                fabric1 base1 npu0-vlink0 npu0-vlink1
1     On-board                  port5 port6 port7 port8
                                fabric2 base2 npu1-vlink0 npu1-vlink1
```

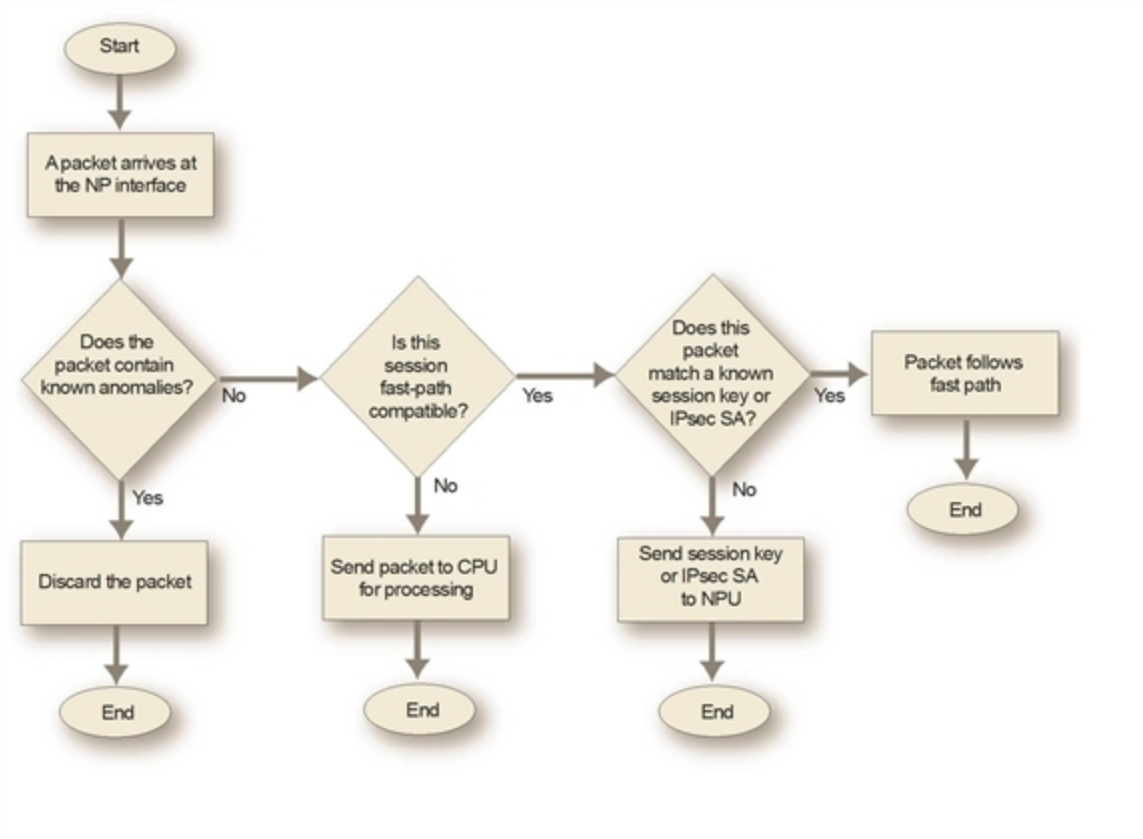
The `npu0-vlink0`, `npu1-vlink1` etc interfaces are used for accelerating inter-VDOM links.

How NP hardware acceleration alters packet flow

NP hardware acceleration generally alters packet flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources (CPU).
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements.
   To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. The list of requirements depends on the processor, see NP6 session fast path requirements on page 1170 or NP4 session fast path requirements on page 1223.
   If the session can be fast pathed, the FortiGate unit sends the session key or IPsec security association (SA) and configured firewall processing action to the appropriate network processor.
3. Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received.
   - If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets that match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See Offloading NP4 anomaly detection on page 1234.
   - The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. This is the actual offloading step. Performing this processing on the NP processor improves overall performance because the NP processor is optimized for this task. As well, overall FortiGate performance is improved because the CPU has fewer sessions to process.

NP network processor packet flow



- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the packet cannot be offloaded. The network processor sends the data to the FortiGate unit's CPU, which processes the packet.

Encryption and decryption of IPsec traffic originating from the FortiGate can utilize network processor encryption capabilities.

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

NP processors and traffic logging and monitoring

Except for the NP6, network processors do not count offloaded packets, and offloaded packets are not logged by traffic logging and are not included in traffic statistics and traffic log reports.

NP6 processors support per-session traffic and byte counters, Ethernet MIB matching, and reporting through messages resulting in traffic statistics and traffic log reporting.

Accelerated sessions on FortiView All Sessions page

When viewing sessions in the FortiView All Sessions console, NP4/ NP6 accelerated sessions are highlighted with an NP4 or NP6 icon. The tooltip for the icon includes the NP processor type and the total number of accelerated sessions.

You can also configure filtering to display FortiASIC sessions.

NP session offloading in HA active-active configuration

Network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

Configuring NP HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks offloaded to network processors by default. You can enter the following command to disable this feature:

```
configure system global
   set ipsec-hmac-offload disable
end
```

Software switch interfaces and NP processors

FortiOS supports creating a software switch by grouping two or more FortiGate physical interfaces into a single virtual or software switch interface. All of the interfaces in this virtual switch act like interfaces in a hardware switch in that they all have the same IP address and can be connected to the same network. You create a software switch interface from the CLI using the command `config system switch-interface`.

The software switch is a bridge group of several interfaces, and the FortiGate CPU maintains the mac-port table for this bridge. As a result of this CPU involvement, traffic processed by a software switch interface is not offloaded to network processors.

Configuring NP accelerated IPsec VPN encryption/decryption offloading

Network processing unit (`npu`) settings configure offloading behavior for IPsec VPN. Configured behavior applies to all network processors in the FortiGate unit.

```
config system npu
   set enc-offload-antireplay {enable | disable}
   set dec-offload-antireplay {enable | disable}
   set offload-ipsec-host {enable | disable}
end
```

Variables	Description	Default
`enc-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec encryption. This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, encryption is always offloaded.	disable
`dec-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec decryption. This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, decryption is always offloaded.	enable
`offload-ipsec-host {enable | disable}`	Enable or disable offloading of IPsec encryption of traffic from local host (FortiGate unit). **Note:** For this option to take effect, the FortiGate unit must have previously sent the security association (SA) to the network processor.	disable

Example

You could configure the offloading of encryption and decryption for an IPsec SA that was sent to the network processor.

```
config system npu
   set enc-offload-antireplay enable
   set dec-offload-antireplay enable
   set offload-ipsec-host enable
end
```

Disabling NP acceleration for individual IPsec VPN phase 1s

Use the following command to disable NP offloading for an interface-based IPsec VPN phase 1:

```
config vpn ipsec phase1-interface
   edit phase-1-name
      set npu-offload disable
end
```

Use the following command to disable NP offloading for a policy-based IPsec VPN phase 1:

```
config vpn ipsec phase1
   edit phase-1-name
      set npu-offload disable
end
```

The `npu-offload` option is enabled by default.

Disabling NP offloading for unsupported IPsec encryption or authentication algorithms

In general, more recent IPsec VPN encryption and authentication algorithms may not be supported by older NP processors. For example, NP4 network processors do not support SHA-256, SHA-384, and SHA-512. IPsec traffic with unsupported algorithms is not offloaded and instead is processed by the FortiGate CPU. In addition, this configuration may cause packet loss and other performance issues. If you experience packet loss or performance

problems you should set the `npu-offload` option to `disable`. Future FortiOS versions should prevent selecting algorithms not supported by the hardware.

Disabling NP offloading for firewall policies

Use the following options to disable NP offloading for specific security policies:

For IPv4 security policies.

```
config firewall policy
   edit 1
      set auto-asic-offload disable
   end
```

For IPv6 security policies.

```
config firewall policy6
   edit 1
      set auto-asic-offload disable
   end
```

For multicast security policies.

```
config firewall multicast-policy
   edit 1
      set auto-asic-offload disable
   end
```

Enabling strict protocol header checking disables all hardware acceleration

You can use the following command to cause the FortiGate to apply strict header checking to verify that a packet is part of a session that should be processed. Strict header checking includes verifying the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options, and verifying that ESP packets have the correct sequence number, SPI, and data length.If the packet fails header checking it is dropped by the FortiGate unit.

```
config system global
   check-protocol-header strict
end.
```

Enabling strict header checking disables all hardware acceleration. This includes NP, SP.and CP processing.

sFlow and NetFlow and hardware acceleration

NP6 offloading is supported when you configure NetFlow for interfaces connected to NP6 processors.

Configuring sFlow on any interface disables all NP4 and NP6 offloading for all traffic on that interface. As well, configuring NetFlow on any interface disables NP4 offloading for all traffic on that interface.

Checking that traffic is offloaded by NP processors

A number of diagnose commands can be used to verify that traffic is being offloaded.

Using the packet sniffer

Use the packet sniffer to verify that traffic is offloaded. Offloaded traffic is not picked up by the packet sniffer so if you are sending traffic through the FortiGate unit and it is not showing up on the packet sniffer you can conclude that it is offloaded.

```
diag sniffer packet port1 <option>
```

Checking the firewall session offload tag

Use the `diagnose sys session list` command to display sessions. If the output for a session includes the `npu info` field you should see information about session being offloaded. If the output doesn't contain an `npu info` field then the session has not been offloaded.

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=34 expire=3565 timeout=3600
    flags=00000000 sockflag=00000000 sockport=0 av_idx=0 use=3
origin-shaper=

Verifying IPsec VPN traffic offloading

The following commands can be used to verify IPsec VPN traffic offloading to NP processors.

```
diagnose vpn ipsec status
NP1/NP2/NP4_0/sp_0_0:
     null: 0 0
     des: 0 0

```

Controlling IPS NPx and CPx acceleration

You can use the following commands to enable or disable acceleration of IPS processing by NPx and CPx processors:

```
config ips global
   set np-accel-mode {none | basic}
   set cp-accel-mode {none | basic | advanced}
end
```

The network processor (NP) acceleration modes are:

`none`: Network Processor acceleration disabled

`basic`: Basic Network Processor acceleration enabled (currently the same as `basic` but will be enhanced in a future FortiOS release).

The content processor (CP) acceleration modes are:

`none`: Content Processor acceleration disabled

`basic`: Basic Content Processor acceleration enabled

`advanced`: Advanced Content Processor acceleration enabled

Dedicated Management CPU

The web-based manager and CLI of FortiGate units with NP6 and NP4 processors may become unresponsive when the system is under heavy processing load because NP6 or NP4 interrupts overload the CPUs preventing CPU cycles from being used for management tasks. You can resolve this issue by using the following command to dedicate CPU core 0 to management tasks.

```
config system npu
   set dedicated-management-cpu {enable | disable}
end
```

All management tasks are then processed by CPU 0 and NP6 or NP4 interrupts are handled by the remaining CPU cores.

Offloading flow-based content inspection with NTurbo and IPSA

You can use the following command to configure NTurbo and IPSA offloading and acceleration of firewall sessions that include flow-based security profiles to NPx and CPx processors. NTurbo and IPSA can offload firewall sessions that include IPS, application control, CASI, flow-based antivirus, and flow-based web filtering security profiles.

```
config ips global
   set np-accel-mode {none | basic}
   set cp-accel-mode {none | basic | advanced}
end
```

NTurbo offloads firewall sessions with flow-based security profiles to NPx processors

NTurbo offloads firewall sessions that include flow-based security profiles to NP4 or NP6 network processors. Without NTurbo, or with NTurbo disabled, all firewall sessions that include flow-based security profiles are processed by the FortiGate CPU.

NTurbo can only offload firewall sessions containing flow-based security profiles if the session could otherwise have been offloaded except for the presence of the flow-based security profiles. If something else prevents the session from being offloaded, NTurbo will not offload that session.

Firewall sessions that include proxy-based security profiles are never offloaded to network processors and are always processed by the FortiGate CPU.

NTurbo creates a special data path to redirect traffic from the ingress interface to IPS, and from IPS to the egress interface. NTurbo allows firewall operations to be offloaded along this path, and still allows IPS to behave as a stage in the processing pipeline, reducing the workload on the FortiGate CPU and improving overall throughput.

NTurbo sessions still offload pattern matching and other processes to CP processors, just like normal flow-based sessions.

If NTurbo is supported by your FortiGate unit, you can use the following command to configure it:

```
config ips global
```

```
    set np-accel-mode {basic | none}
end
```

`basic` enables NTurbo and is the default setting for FortiGate models that support NTurbo. `none` disables NTurbo. If the `np-accel-mode` option is not available, then your FortiGate does not support NTurbo.

There are some special cases where sessions may not be offloaded by NTurbo, even when NTurbo is explicitly enabled. In these cases the sessions are handled by the FortiGate CPU.

- NP acceleration is disabled. For example, `auto-asic-offload` is disabled in the firewall policy configuration.
- The firewall policy includes proxy-based security profiles.
- The sessions require FortiOS session-helpers. For example, FTP sessions can not be offloaded to NP processors because FTP sessions use the FTP session helper.
- Interface policies or DoS policies have been added to the ingress or egress interface.
- Tunneling is enabled. Any traffic to or from a tunnelled interface (IPSec, IPinIP, SSL VPN, GRE, CAPWAP etc.) cannot be offloaded by NTurbo.

IPSA offloads flow-based enhanced pattern matching to CPx processors

IPSA offloads enhanced pattern matching operations required for flow-based content processing to Content Processors (CPs) such as the CP7, CP8 and CP9. IPSA offloads enhanced pattern matching for NTurbo firewall sessions and firewall sessions that are not offloaded to NP processors. When IPSA is turned on, flow-based pattern databases are compiled and downloaded to the content processors. Flow-based pattern matching requests are redirected to the CP hardware reducing the load on the FortiGate CPU. In addition the CP processors accelerate pattern matching.

IF IPSA is supported on your FortiGate unit, you can use the following command to configure it:

```
config ips global
   set cp-accel-mode {advanced | basic | none}
end
```

`basic` offloads basic pattern matching. `advanced` offloads more types of pattern matching resulting in higher throughput than basic mode. `advanced` is only available on FortiGate models with two or more CP8 processors or one or more CP9 processors. If the `cp-accel-mode` option is not available, then your FortiGate does not support IPSA.

On FortiGates with one CP7 or CP8 processor the default `cp-accel-mode` is `basic`.Setting the mode to `advanced` does not change the types of pattern matching that are offloaded.

On FortiGates with two or more CP8 processors or one or more CP9 processors the default `cp-accel-mode` is `advanced`. You can set the mode to `basic` to offload fewer types of pattern matching.

NP6 Acceleration

NP6 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6.

The key to making this possible is an Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. Many FortiGate units with NP6 processors also have an ISF. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF. There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF.

Some FortiGate units, such as the FortiGate-1000D include multiple NP6 processors that are not connected by an ISF. Because the ISF is not present fast path acceleration is supported only between interfaces connected to the same NP6 processor. Since the ISF introduces some latency, models with no ISF provide low-latency network acceleration between network interfaces connected to the same NP6 processor.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.
- Some FortiGate units may use some NP6 processors for special functions. For example, ports 25 to 32 of the FortiGate-3700D can be used for low latency offloading.

NP6 session fast path requirements

NP6 processors can offload the following traffic and services:

- IPv4 and IPv6 traffic and NAT64 and NAT46 traffic (as well as IPv4 and IPv6 versions of the following traffic types where appropriate)
- Link aggregation (LAG) (IEEE 802.3ad) traffic (see Increasing NP6 offloading capacity using link aggregation groups (LAGs) on page 1175)
- TCP, UDP, ICMP and SCTP traffic
- IPsec VPN traffic, and offloading of IPsec encryption/decryption (including SHA2-256 and SHA2-512)
- Anomaly-based intrusion prevention, checksum offload and packet defragmentation
- SIT and IPv6 Tunnelling sessions

- Multicast traffic (including Multicast over IPsec)
- CAPWAP and wireless bridge traffic tunnel encapsulation to enable line rate wireless forwarding from FortiAP devices
- Traffic shaping and priority queuing for both shared and per IP traffic shaping.
- Syn proxying
- Inter-VDOM link traffic

Sessions that are offloaded must be fast path ready. For a session to be fast path ready it must meet the following criteria:

- Layer 2 type/length must be 0x0800 for IPv4 or 0x86dd for IPv6 (IEEE 802.1q VLAN specification is supported)
- Layer 3 protocol can be IPv4 or IPv6
- Layer 4 protocol can be UDP, TCP, ICMP, or SCTP
- In most cases, Layer 3 / Layer 4 header or content modification sessions that require a session helper can be offloaded.
- Local host traffic (originated by the FortiGate unit) can be offloaded
- If the FortiGate supports, NTurbo sessions can be offloaded if they are accepted by firewall policies that include IPS, Application Control, flow-based antivirus, or flow-based web filtering.

Offloading Application layer content modification is not supported. This means that sessions are not offloaded if they are accepted by firewall policies that include proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, email filtering, VoIP, ICAP, or Proxy options.

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See Configuring individual NP6 processors on page 1178.

If a session or is not fast path ready, the FortiGate unit will not send the session key or IPsec SA key to the NP6 processor. Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key or IPsec SA key to the network processor. Session key or IPsec SA key lookups then succeed for subsequent packets from the known session or IPsec SA.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for a network processor's network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP6.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

NP6 processors and traffic shaping

NP6-offloaded traffic supports traffic shaping just like any other traffic with one exception: configuring in bandwith traffic shaping has no effect on NP6 accelerated traffic. In bandwidth traffic shaping sets the bandwidth limit for incoming traffic for an interface.

Out bandwidth traffic shaping is supported. Out bandwidth traffic shaping sets the bandwidth limit for outgoing traffic for an interface. You can use the following command to configure out bandwidth traffic shaping:

```
config system interface
   edit port1
      set outbandwidth 2000
   end
```

Viewing your FortiGate NP6 processor configuration

Use the following command to view the NP6 processor configuration of your FortiGate unit:

```
diagnose npu np6 port-list
```

For example output of this command for different FortiGate models, see FortiGate NP6 architectures on page 1185.

Use either of the following commands to view the NP6 processor hardware configuration of your FortiGate unit:

```
get hardware npu np6 port-list
diagnose npu np6 port-list
```

For example, for the FortiGate-5001D the output would be:

```
get hardware npu np6 port-list
Chip   XAUI Ports            Max   Cross-chip
                             Speed offloading
------ ---- -------          ----- ----------
np6_0  0    port3            10G   Yes
       1
       2    base1            1G    Yes
       3
       0-3  port1            40G   Yes
       0-3  fabric1          40G   Yes
       0-3  fabric3          40G   Yes
       0-3  fabric5          40G   Yes
------ ---- -------          ----- ----------
np6_1  0
       1    port4            10G   Yes
       2
       3    base2            1G    Yes
       0-3  port2            40G   Yes
       0-3  fabric2          40G   Yes
       0-3  fabric4          40G   Yes
------ ---- -------          ----- ----------
```

For more example output for different FortiGate models, see FortiGate NP6 architectures on page 1.

You can also use the following command to view the offloading features enabled or disabled on each of the NP6 processors in your FortiGate unit:

```
diagnose npu np6 npu-feature
                    np_0      np_1
------------------- --------- ---------
Fastpath            Enabled   Enabled
Low-latency-mode    Disabled  Disabled
Low-latency-cap     No        No
IPv4 firewall       Yes       Yes
IPv6 firewall       Yes       Yes
IPv4 IPSec          Yes       Yes
IPv6 IPSec          Yes       Yes
IPv4 tunnel         Yes       Yes
IPv6 tunnel         Yes       Yes
GRE tunnel          No        No
IPv4 Multicast      Yes       Yes
IPv6 Multicast      Yes       Yes
CAPWAP              Yes       Yes
```

Optimizing NP6 performance by distributing traffic to XAUI links

On most FortiGate units with NP6 processors, the FortiGate interfaces are switch ports that connect to the NP6 processors with XAUI links. Packets pass from the interfaces to the NP6 processor over the XAUI links. Each NP6 processor has a 40 Gigabit bandwidth capacity. The four XAUI links each have a 10 Gigabit capacity for a total of 40 Gigabits.

On many FortiGate units with NP6 processors, the NP6 processors and the XAUI links are over-subscribed. Since the NP6 processors are connected by an Integrated Switch Fabric, you do not have control over how traffic is distributed to them. In fact traffic is distributed evenly by the ISF.

However, you can control how traffic is distributed to the XAUI links and you can optimize performance by distributing traffic evenly among the XAUI links. For example, if you have a very high amount of traffic passing between two networks, you can connect each network to interfaces connected to different XAUI links to distribute the traffic for each network to a different XAUI link.

For example, on a FortiGate-3200D (See Optimizing NP6 performance by distributing traffic to XAUI links), there are 48 10-Gigabit interfaces that send and receive traffic for two NP6 processors over a total of eight 10-Gigabit XAUI links. Each XAUI link gets traffic from six 10-Gigabit FortiGate interfaces. The amount of traffic that the FortiGate-3200D can offload is limited by the number of NP6 processors and the number of XAUI links. You can optimize the amount of traffc that the FortiGate-3200D can process by distributing it evenly amount the XAUI links and the NP6 processors.

You can see the Etherent interface, XAUI link, and NP6 configuration by entering the `get hardware npu np6 port-list` command. For the FortiGate-3200D the output is:

```
get hardware npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading
------ ---- ------- ----- ----------
np6_0  0    port1   10G   Yes
       0    port5   10G   Yes
       0    port10  10G   Yes
       0    port13  10G   Yes
```

```
        0    port17  10G   Yes
        0    port22  10G   Yes
        1    port2   10G   Yes
        1    port6   10G   Yes
        1    port9   10G   Yes
        1    port14  10G   Yes
        1    port18  10G   Yes
        1    port21  10G   Yes
        2    port3   10G   Yes
        2    port7   10G   Yes
        2    port12  10G   Yes
        2    port15  10G   Yes
        2    port19  10G   Yes
        2    port24  10G   Yes
        3    port4   10G   Yes
        3    port8   10G   Yes
        3    port11  10G   Yes
        3    port16  10G   Yes
        3    port20  10G   Yes
        3    port23  10G   Yes
------ ---- ------- ----- ----------
np6_1   0    port26  10G   Yes
        0    port29  10G   Yes
        0    port33  10G   Yes
        0    port37  10G   Yes
        0    port41  10G   Yes
        0    port45  10G   Yes
        1    port25  10G   Yes
        1    port30  10G   Yes
        1    port34  10G   Yes
        1    port38  10G   Yes
        1    port42  10G   Yes
        1    port46  10G   Yes
        2    port28  10G   Yes
        2    port31  10G   Yes
        2    port35  10G   Yes
        2    port39  10G   Yes
        2    port43  10G   Yes
        2    port47  10G   Yes
        3    port27  10G   Yes
        3    port32  10G   Yes
        3    port36  10G   Yes
        3    port40  10G   Yes
        3    port44  10G   Yes
        3    port48  10G   Yes
------ ---- ------- ----- ----------
```

In this command output you can see that each NP6 has for four XAUI links (0 to 3) and that each XAUI link is connected to six 10-gigabit Ethernet interfaces. To optimize throughput you should keep the amount of traffic being processed by each XAUI port to under 10 Gbps. So for example, if you want to offload traffic from four 10-gigabit networks you can connect these networks to Ethernet interfaces 1, 2, 3 and 4. This distributes the traffic from each 10-Gigabit network to a different XAUI link. Also, if you wanted to offload traffic from four more 10-

Gigabit networks you could connect them to Ethernet ports 26, 25, 28, and 27. As a result each 10-Gigabit network would be connected to a different XAUI link.

Increasing NP6 offloading capacity using link aggregation groups (LAGs)

NP6 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A 802.3ad Link Aggregation and it's management protocol, Link Aggregation Control Protocol (LACP) LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 30 Gbps link by adding three 10-Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP6 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP6 processor, traffic received by that LAG is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

If a FortiGate has two or more NP6 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP6 processors. You do this by adding physical interfaces connected to different NP6 processors to the same LAG.

Adding a second NP6 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP6 or tripled by adding a thrid. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP6s is supported by the integrated switch fabric (ISF) that allows multiple NP6 processors to share session information. Most FortiGate units with multiple NP6 processors also have an ISF. However, the FortiGate-1000D does not have an ISF. On this model and others that have more than one NP6 and no ISF, if you attempt to add interfaces connected to different NP6 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP6 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPSec is configured on a LAG that has interfaces connected to multiple NP6 processors.
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only can be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP6 LAG group to 10Gbps.

Configuring Inter-VDOM link acceleration with NP6 processors

FortiGate units with NP6 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP6 processors there are two accelerated inter-VDOM links, each with two interfaces:
  - **npu0_vlink:**
    npu0_vlink0
    npu0_vlink1
  - **npu1_vlink:**
    npu1_vlink0
    npu1_vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP6 interfaces, enter the following CLI command to display the NP6-accelerated inter-VDOM links:

```
get system interface
...
== [ npu0_vlink0 ]
name: npu0_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
    type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
    disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
    fragment: disable

== [ npu0_vlink1 ]
name: npu0_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
    type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
    disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
    fragment: disable

== [ npu1_vlink0 ]
name: npu1_vlink0 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
    type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
    disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
    fragment: disable

== [ npu1_vlink1 ]
name: npu1_vlink1 mode: static ip: 0.0.0.0 0.0.0.0 status: down netbios-forward: disable
    type: physical sflow-sampler: disable explicit-web-proxy: disable explicit-ftp-proxy:
    disable mtu-override: disable wccp: disable drop-overlapped-fragment: disable drop-
    fragment: disable
...
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in the pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**. This results in an accelerated inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
   edit npu0-vlink1
      set vdom New-VDOM
end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0_vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0_vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
   edit Marketing-link
      set vdom Marketing
      set ip 172.20.120.12/24
      set interface npu0_vlink0
      set vlanid 100
   next
   edit Engineering-link
      set vdom Engineering
      set ip 172.20.120.22/24
      set interface npu0_vlink1
      set vlanid 100
```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP6 processor.

```
diagnose ip address list
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55 devname=IVL-VLAN1_ROOT
IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56 devname=IVL-VLAN1_VDOM1
```

```

Configuring individual NP6 processors

You can use the `config system np6` command to configure a wide range of settings for the NP6 processors in your FortiGate unit including enabling/disabling fastpath and low latency and adjusting session timeouts. As well you can set anomaly checking for IPv4 and IPv6 traffic. You can also configure different settings for each NP6 processor.

The settings that you configure for an NP6 processor with the `config system np6` command apply to traffic processed by all interfaces connected to the NP6 processor. This includes the physical interfaces connected to the NP6 processor as well as all subinterfaces, VLAN interfaces, IPsec interfaces, LAGs and so on associated with the physical interfaces connected to the NP6 processor.

Some of the options for this command apply anomaly checking for NP6 sessions in the same way as the command described in Offloading NP4 anomaly detection on page 1234 applies anomaly checking for for NP4 sessions.

```
config system np6
   edit <np6-processor-name>
      set fastpath {disable | enable}
      set low-latency-mode {disable | enable}
      set per-session-accounting {disable | enable}
      set session-timeout-random-range <range>
      set garbage-session-collector {disable | enable}
      set session-collector-interval <range>
      set session-timeout-interval <range>
      set session-timeout-random-range <range>
      set session-timeout-fixed {disable | enable}
         config fp-anomaly-v4
            set icmp-frag {allow | drop | trap-to-host}
            set icmp-land {allow | drop | trap-to-host}
            set ipv4-land {allow | drop | trap-to-host}
            set ipv4-optlsrr {allow | drop | trap-to-host}
            set ipv4-optrr {allow | drop | trap-to-host}
            set ipv4-optsecurity {allow | drop | trap-to-host}
            set ipv4-optssrr {allow | drop | trap-to-host}
            set ipv4-optstream {allow | drop | trap-to-host}
            set ipv4-opttimestamp {allow | drop | trap-to-host}
            set ipv4-proto-err {allow | drop | trap-to-host}
            set ipv4-unknopt {allow | drop | trap-to-host}
            set tcp-land {allow | drop | trap-to-host}
            set tcp-syn-fin {allow | drop | trap-to-host}
            set tcp-winnuke {allow | drop | trap-to-host}
            set tcp_fin_noack {allow | drop | trap-to-host}
            set tcp_fin_only {allow | drop | trap-to-host}
            set tcp_no_flag {allow | drop | trap-to-host}
            set tcp_syn_data {allow | drop | trap-to-host}
            set udp-land {allow | drop | trap-to-host}
         end
         config fp-anomaly-v6
            set ipv6-daddr_err {allow | drop | trap-to-host}
            set ipv6-land {allow | drop | trap-to-host}
            set ipv6-optendpid {allow | drop | trap-to-host}
            set ipv6-opthomeaddr {allow | drop | trap-to-host}
            set ipv6-optinvld {allow | drop | trap-to-host}
            set ipv6-optjumbo {allow | drop | trap-to-host}
            set ipv6-optnsap {allow | drop | trap-to-host}
            set ipv6-optralert {allow | drop | trap-to-host}
            set ipv6-opttunnel {allow | drop | trap-to-host}
            set ipv6-proto-err {allow | drop | trap-to-host}
            set ipv6-saddr_err {allow | drop | trap-to-host}
            set ipv6-unknopt {allow | drop | trap-to-host}
         end
```

Command syntax

Command	Description	Default
`fastpath {disable | enable}`	Enable fastpath acceleration to offload sessions to the NP6 processor. You can disable fastpath if you don't want the NP6 processor to offload sessions.	enable
`low-latency-mode {disable | enable}`	Enable low-latency mode. In low latency mode the integrated switch fabric is bypassed. Low latency mode requires that packet enter and exit using the same NP6 processor. This option is only available for NP6 processors that can operate in low-latency mode.	disable
`per-session-accounting {disable | enable}`	Record traffic log messages for offloaded sessions. Enabling this feature reduces performance..	disable
`garbage-session-collector {disable | enable}`	Enable deleting expired or garbage sessions.	disable
`session-collector-interval <range>`	Set the expired or garbage session collector time interval in seconds. The range is 1 to 100 seconds.	8
`session-timeout-interval <range>`	Set the timeout for inactive sessions. The range is 0 to 1000 seconds.	40
`session-timeout-random-range <range>`	Set the random timeout for inactive sessions. The range is 0 to 1000 seconds.	8
`session-timeout-fixed {disable | enable}`	Force session timeouts at fixed instead of random intervals.	disable
config fp-anomaly-v4		
`fp-anomaly-v4`	Configure how the NP6 processor does IPv4 traffic anomaly protection. You can configure the NP6 processor to allow or drop the packets associated with an attack or forward the packets that are associated with the attack to FortiOS (called "trap-to-host"). Selecting "trap-to-host" turns off NP6 anomaly protection for that anomaly. If you require anomaly protection you can enable it with a DoS policy.	
`icmp-frag {allow | drop | trap-to-host}`	Detects Layer 3 fragmented packets that could be part of a layer 4 ICMP anomalies.	allow
`icmp-land {allow | drop | trap-to-host}`	Detects ICMP land anomalies.	trap-to-host
`ipv4-land {allow | drop | trap-to-host}`	Detects IPv4 land anomalies.	trap-to-host

Command	Description	Default
`ipv4-optlsrr {allow | drop | trap-to-host}`	Detects IPv4 with loose source record route option anomalies.	trap-to-host
`ipv4-optrr {allow | drop | trap-to-host}`	Detects IPv4 with record route option anomalies.	trap-to-host
`ipv4-optsecurity {allow | drop | trap-to-host}`	Detects security option anomalies.	trap-to-host
`ipv4-optssrr {allow | drop | trap-to-host}`	Detects IPv4 with strict source record route option anomalies.	trap-to-host
`ipv4-optstream {allow | drop | trap-to-host}`	Detects stream option anomalies.	trap-to-host
`ipv4-opttimestamp {allow | drop | trap-to-host}`	Detects timestamp option anomalies.	trap-to-host
`ipv4-proto-err {allow | drop | trap-to-host}`	Detects invalid layer 4 protocol anomalies.	trap-to-host
`ipv4-unknopt {allow | drop | trap-to-host}`	Detects unknown option anomalies.	trap-to-host
`tcp-land {allow | drop | trap-to-host}`	Detects TCP land anomalies.	trap-to-host
`tcp-syn-fin {allow | drop | trap-to-host}`	Detects TCP SYN flood SYN/FIN flag set anomalies.	allow
`tcp-winnuke {allow | drop | trap-to-host}`	Detects TCP WinNuke anomalies.	trap-to-host
`tcp_fin_noack {allow | drop | trap-to-host}`	Detects TCP SYN flood with FIN flag set without ACK setting anomalies.	trap-to-host
`tcp_fin_only {allow | drop | trap-to-host}`	Detects TCP SYN flood with only FIN flag set anomalies.	trap-to-host
`tcp_no_flag {allow | drop | trap-to-host}`	Detects TCP SYN flood with no flag set anomalies.	allow
`tcp_syn_data {allow | drop | trap-to-host}`	Detects TCP SYN flood packets with data anomalies.	allow
`udp-land {allow | drop | trap-to-host}`	Detects UDP land anomalies.	trap-to-host

Command	Description	Default
config fp-anomaly-v6		
`fp-anomaly-v6`	Configure how the NP6 processor does IPv6 traffic anomaly protection. You can configure the NP6 processor to allow or drop the packets associated with an attack or forward the packets that are associated with the attack to FortiOS (called “trap-to-host”). Selecting “trap-to-host” turns off NP6 anomaly protection for that anomaly. If you require anomaly protection you can enable it with a DoS policy.	
`ipv6-daddr_err {allow | drop | trap-to-host}`	Detects destination address as unspecified or loopback address anomalies.	trap-to-host
`ipv6-land {allow | drop | trap-to-host}`	Detects IPv6 land anomalies	trap-to-host
`ipv6-optendpid {allow | drop | trap-to-host}`	Detects end point identification anomalies.	trap-to-host
`ipv6-opthomeaddr {allow | drop | trap-to-host}`	Detects home address option anomalies.	trap-to-host
`ipv6-optinvld {allow | drop | trap-to-host}`	Detects invalid option anomalies.	trap-to-host
`ipv6-optjumbo {allow | drop | trap-to-host}`	Detects jumbo options anomalies.	trap-to-host
`ipv6-optnsap {allow | drop | trap-to-host}`	Detects network service access point address option anomalies.	trap-to-host
`ipv6-optralert {allow | drop | trap-to-host}`	Detects router alert option anomalies.	trap-to-host
`ipv6-opttunnel {allow | drop | trap-to-host}`	Detects tunnel encapsulation limit option anomalies.	trap-to-host
`ipv6-proto-err {allow | drop | trap-to-host}`	Detects layer 4 invalid protocol anomalies.	trap-to-host
`ipv6-saddr_err {allow | drop | trap-to-host}`	Detects source address as multicast anomalies.	trap-to-host
`ipv6-unknopt {allow | drop | trap-to-host}`	Detects unknown option anomalies.	trap-to-host

Enabling per-session accounting for offloaded NP6 sessions

By default FortiOS does not record log messages for offloaded NP6 and NP4 sessions. This also means that traffic monitoring does not report correct session counts, byte counts and packet counts for offloaded NP6 and NP4 sessions.

However, for NP6 processors, you can use the following command to enable per-session accounting for each NP6 processor in the FortiGate unit. Per session accounting is a logging feature that allows the FortiGate to report the correct bytes/pkt numbers per session for sessions offloaded to an NP6 processor. Per-session accounting is not enabled by default because it reduces NP6 offloading performance. So you should only enable per-session accounting if you need the accounting information.

Some FortiOS versions enable per-session-accounting automatically if you enable traffic logging in a firewall policy that allows traffic to pass through an interface attached to an NP6 processor.

Enabling per-session accounting only supports traffic log messages and does not provide traffic flow data for sFlow or NetFlow.

For example, to enable session accounting for the first and second NP6 processors (np6_0 and np6_1):

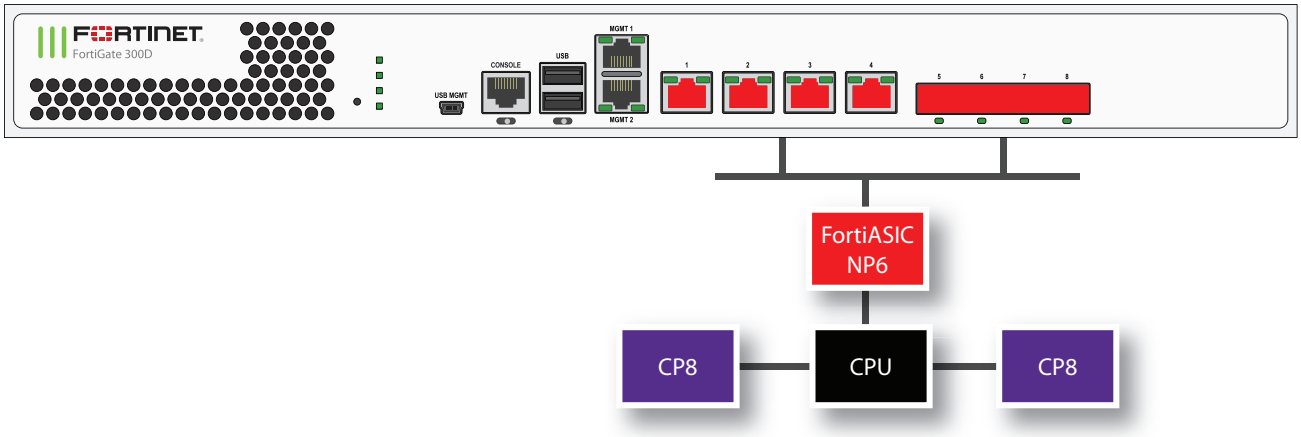
```
config system np6
   edit np6_0
      set per-session-accounting enable
   next
   edit np6_1
      set per-session-accounting enable
   end
```

FortiGate NP6 architectures

Many FortiGate models can offload some types of network traffic processing from main processing resources to specialized network processors. If your network has a significant volume of traffic that is suitable for offloading, this hardware acceleration can significantly improve your network throughput.

FortiGate-300D fast path architecture

The FortiGate-300D includes one NP6 processor connected to four 1Gb RJ-45 Ethernet ports (port1-4) and four 1Gb SFP interfaces (port5-port8).

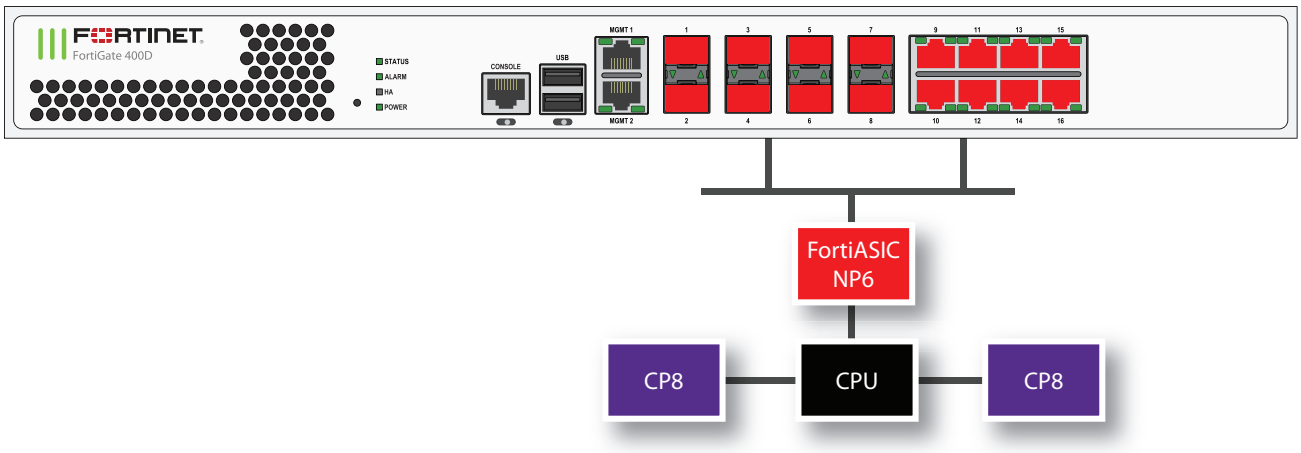


You can use the following command to display the FortiGate-300D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it.

```
diagnose npu np6 port-list
Chip    XAUI Ports    Max    Cross-chip
                      Speed offloading
------ ---- ------- ----- ----------
np6_0   0
        1    port5   1G    Yes
        1    port7   1G    Yes
        1    port8   1G    Yes
        1    port6   1G    Yes
        1    port3   1G    Yes
        1    port4   1G    Yes
        1    port1   1G    Yes
        1    port2   1G    Yes
        2
        3
------ ---- ------- ----- ----------
```

FortiGate-400D fast path architecture

The FortiGate-400D includes one NP6 processor connected to eight 1Gb SFP interfaces (port1-port8) and eight 1Gb RJ-45 Ethernet ports (port9-16).

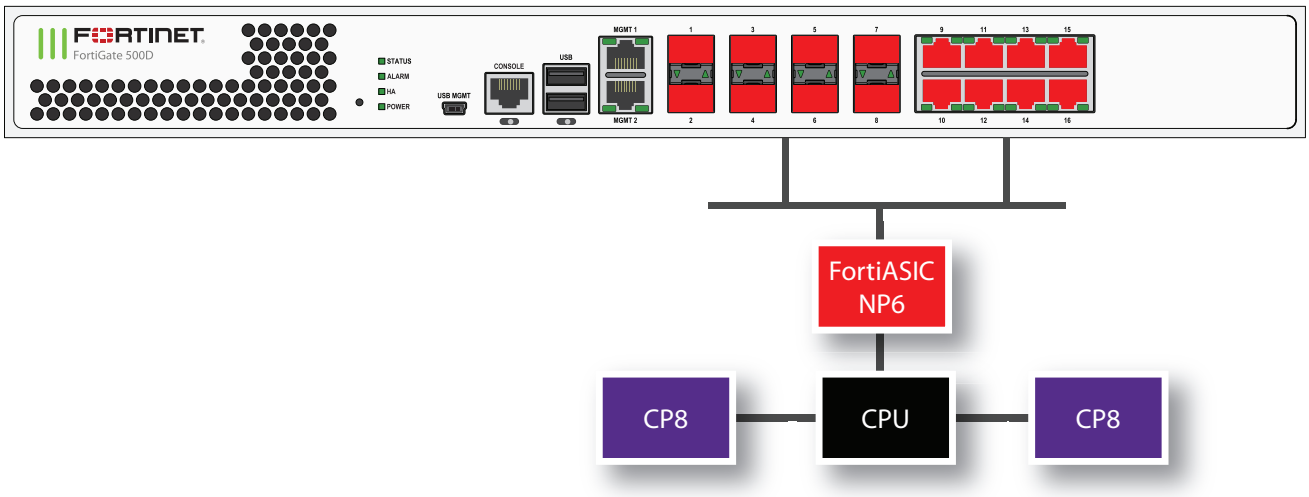


You can use the following command to display the FortiGate-400D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it.

```
diagnose npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading
------ ---- ------- ----- ----------
np6_0  0
       1    port10  1G    Yes
       1    port9   1G    Yes
       1    port12  1G    Yes
       1    port11  1G    Yes
       1    port14  1G    Yes
       1    port13  1G    Yes
       1    port16  1G    Yes
       1    port15  1G    Yes
       1    port5   1G    Yes
       1    port7   1G    Yes
       1    port8   1G    Yes
       1    port6   1G    Yes
       1    port3   1G    Yes
       1    port4   1G    Yes
       1    port1   1G    Yes
       1    port2   1G    Yes
       2
       3
------ ---- ------- ----- ----------
```

FortiGate-500D fast path architecture

The FortiGate-500D includes one NP6 processor connected to eight 1Gb SFP interfaces (port1-port8) and eight 1Gb RJ-45 Ethernet ports (port9-16).

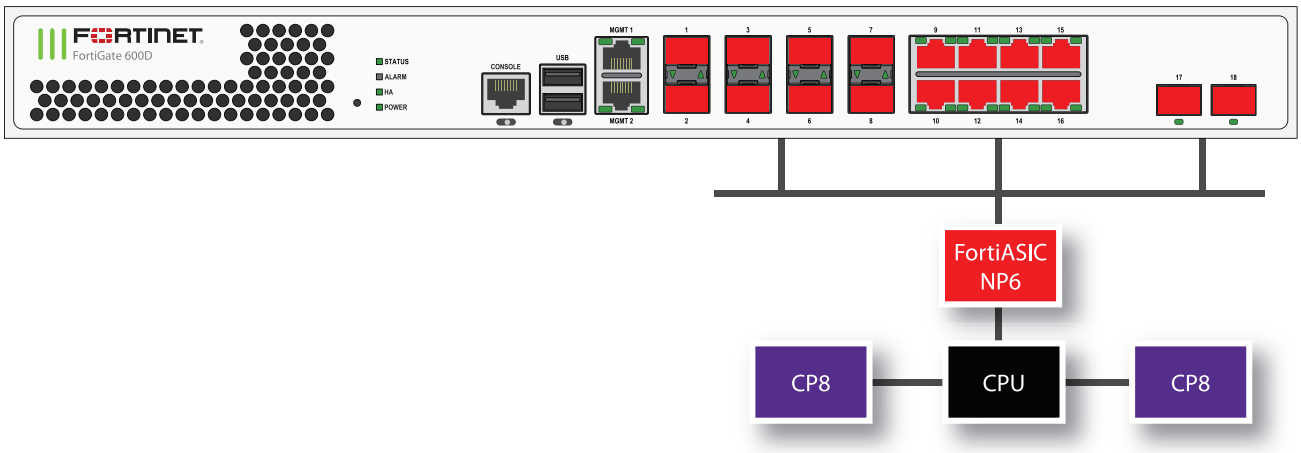


You can use the following command to display the FortiGate-500D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it.

```
diagnose npu np6 port-list
Chip    XAUI Ports    Max    Cross-chip
                     Speed offloading
------ ---- ------- ----- ----------
np6_0  0
        1    port10  1G    Yes
        1    port9   1G    Yes
        1    port12  1G    Yes
        1    port11  1G    Yes
        1    port14  1G    Yes
        1    port13  1G    Yes
        1    port16  1G    Yes
        1    port15  1G    Yes
        1    port5   1G    Yes
        1    port7   1G    Yes
        1    port8   1G    Yes
        1    port6   1G    Yes
        1    port3   1G    Yes
        1    port4   1G    Yes
        1    port1   1G    Yes
        1    port2   1G    Yes
        2
        3
------ ---- ------- ----- ----------
```

FortiGate-600D fast path architecture

The FortiGate-600D includes one NP6 processor connected to eight 1Gb SFP interfaces (port1-port8) and eight 1Gb RJ-45 Ethernet ports (port9-16) and two 10Gb SFP+ interfaces (port17 and port18).

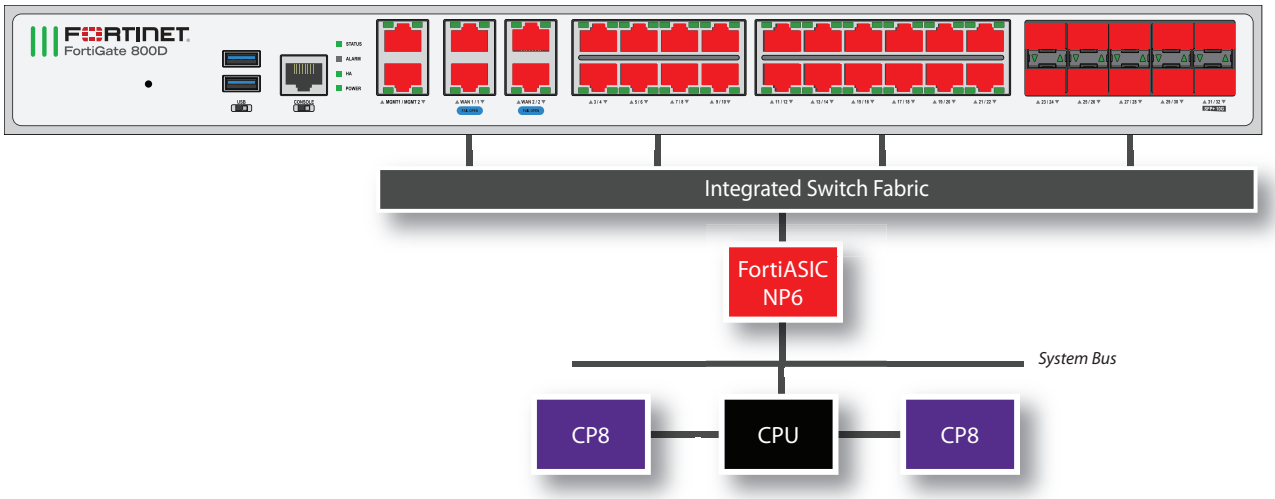


You can use the following command to display the FortiGate-600D NP6 configuration. The command output shows one NP6 named NP6_0 and the interfaces (ports) connected to it.

```
diagnose npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading
------ ---- ------- ----- ----------
np6_0  0
       1    port10  1G    Yes
       1    port9   1G    Yes
       1    port12  1G    Yes
       1    port11  1G    Yes
       1    port14  1G    Yes
       1    port13  1G    Yes
       1    port16  1G    Yes
       1    port15  1G    Yes
       1    port5   1G    Yes
       1    port7   1G    Yes
       1    port8   1G    Yes
       1    port6   1G    Yes
       1    port3   1G    Yes
       1    port4   1G    Yes
       1    port1   1G    Yes
       1    port2   1G    Yes
       2    port17  10G   Yes
       3    port18  10G   Yes
------ ---- ------- ----- ----------
```

FortiGate-800D fast path architecture

The FortiGate-800D includes one NP6 processor connected through an integrated switch fabric to all of the FortiGate-800D network interfaces. This hardware configuration supports NP6-accelerated fast path offloading for sessions between any of the FortiGate-800D interfaces.



You can use the following diagnose command to display the FortiGate-800D NP6 configuration. The command output shows one NP6 named NP6_0. The output also shows all of the FortiGate-800D interfaces (ports) connected to NP6_0.

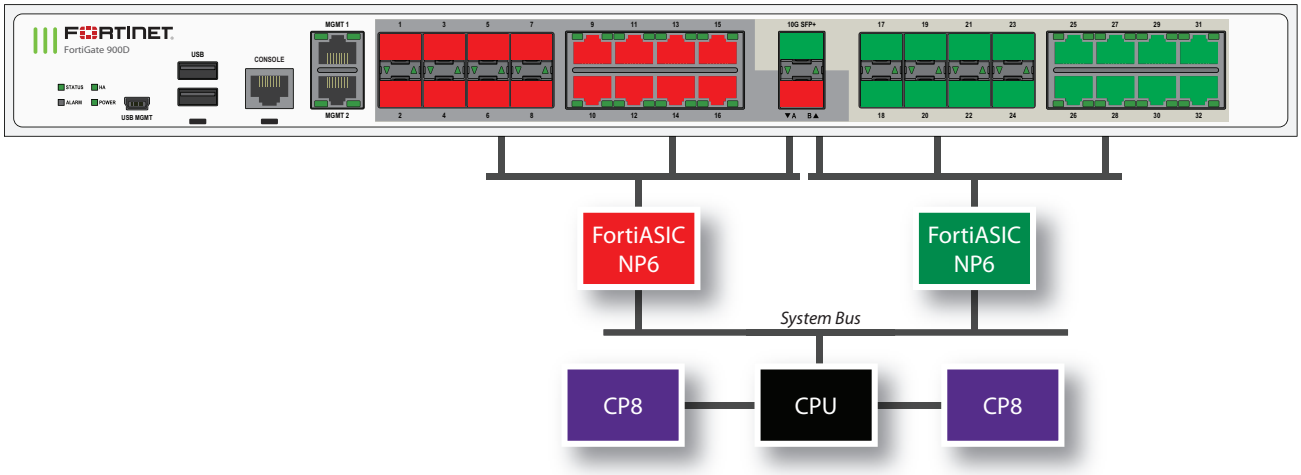
```
diagnose npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading
------ ---- ------- ----- ----------
np6_0  0    port31  10G   Yes
       1    wan1    1G    Yes
       1    port1   1G    Yes
       1    wan2    1G    Yes
       1    port2   1G    Yes
       1    port3   1G    Yes
       1    port4   1G    Yes
       1    port5   1G    Yes
       1    port6   1G    Yes
       1    port30  1G    Yes
       1    port29  1G    Yes
       1    port28  1G    Yes
       1    port27  1G    Yes
       1    port26  1G    Yes
       1    port25  1G    Yes
       1    port24  1G    Yes
       1    port23  1G    Yes
       2    port7   1G    Yes
       2    port8   1G    Yes
       2    port9   1G    Yes
       2    port10  1G    Yes
       2    port11  1G    Yes
       2    port12  1G    Yes
       2    port13  1G    Yes
       2    port14  1G    Yes
       2    port15  1G    Yes
       2    port16  1G    Yes
       2    port17  1G    Yes
       2    port18  1G    Yes
       2    port19  1G    Yes
       2    port20  1G    Yes
       2    port21  1G    Yes
       2    port22  1G    Yes
       3    port32  10G   Yes
------ ---- ------- ----- ----------
```

FortiGate-900D fast path architecture

The FortiGate-900D includes two NP6 processors that are not connected by an integrated switch fabric (ISF). Without an ISF, traffic through a FortiGate-900D could experience lower latency than traffic through similar hardware with an ISF. The NP6 processors are connected to network interfaces as follows:

Because the FortiGate-900D does not have an ISF you cannot create Link Aggregation Groups (LAGs) that include interfaces connected to both NP6 processors.

- Eight 1Gb SFP interfaces (port17-port24), eight 1Gb RJ-45 Ethernet interfaces (port25-32) and one 10Gb SFP+ interface (portB) share connections to the first NP6 processor.
- Eight 1Gb SFP interfaces (port1-port8), eight RJ-45 Ethernet interfaces (port9-16) and one 10Gb SFP+ interface (portA) share connections to the second NP6 processor.



You can use the following command to display the FortiGate-900D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

```
diagnose npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading

        3
```

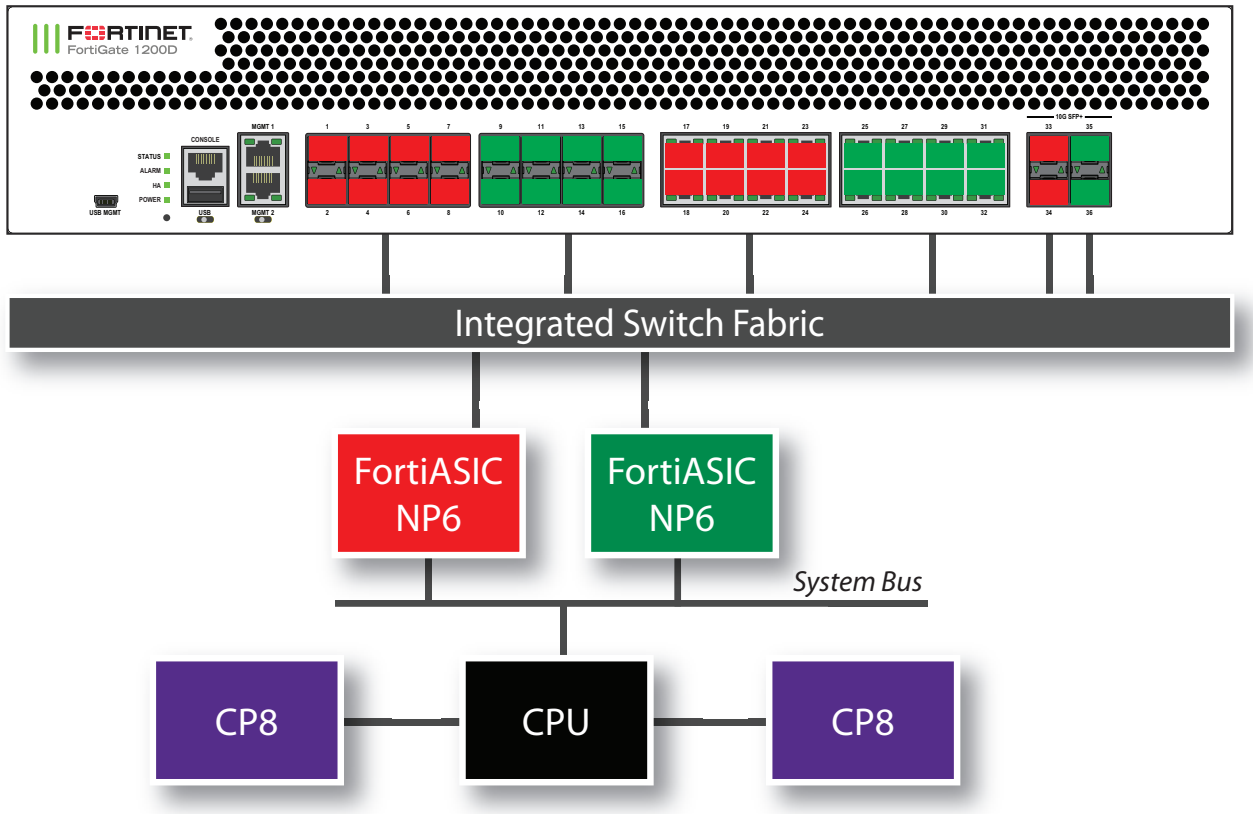
FortiGate-1200D fast path architecture

The FortiGate-1200D features two NP6 processors both connected to an integrated switch fabric.

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and two SFP+ 10Gb interfaces (port33 and port34) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and two SFP+ 10Gb interfaces (port35-port36) share connections to the second NP6 processor.



You can use the following command to display the FortiGate-1200D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

```
diagnose npu np6 port-list
Chip   XAUI Ports   Max   Cross-chip
                    Speed offloading
------ ---- ------- ----- ----------
np6_0  0    port33  10G   Yes
       1    port34  10G   Yes
       2    port1   1G    Yes
       2    port3   1G    Yes
       2    port5   1G    Yes
       2    port7   1G    Yes

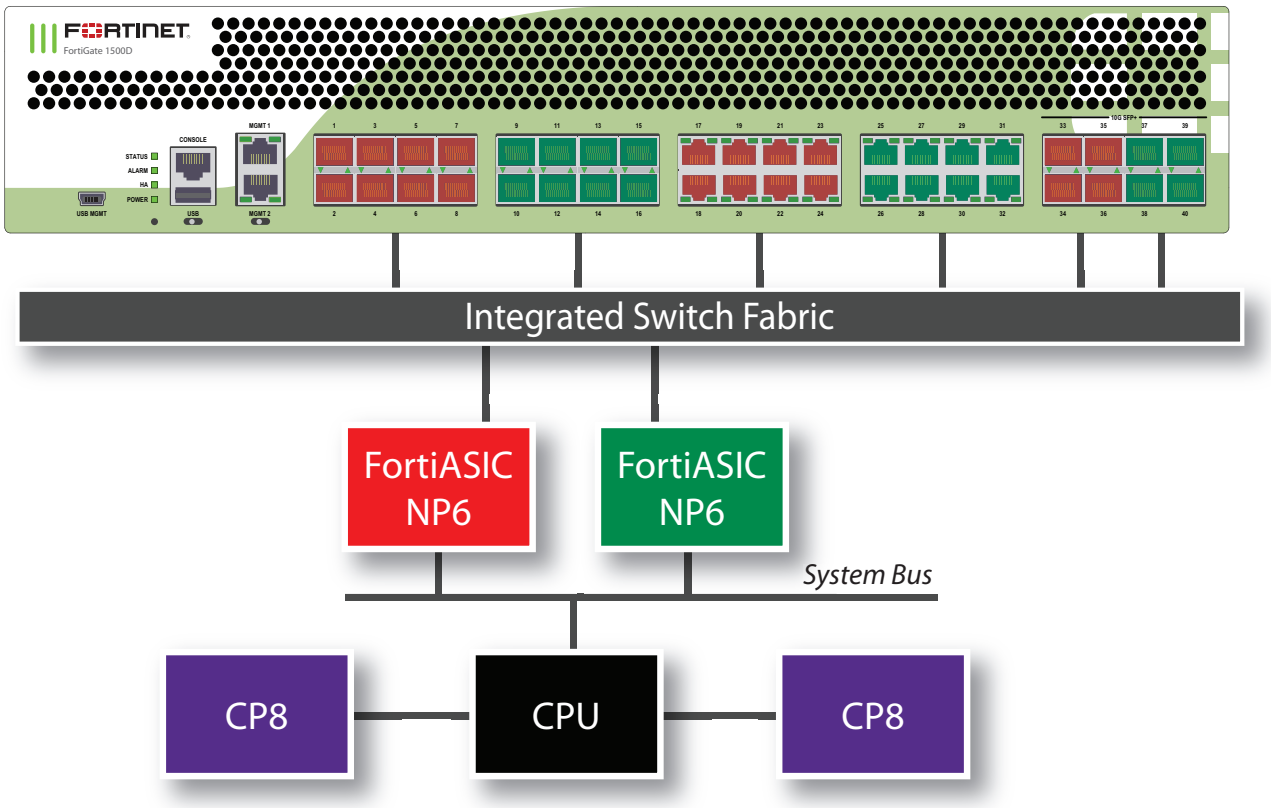
FortiGate-1500D fast path architecture

The FortiGate-1500D features two NP6 processors both connected to an integrated switch fabric.

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and four SFP+ 10Gb interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.



You can use the following diagnose command to display the FortiGate-1500D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

```

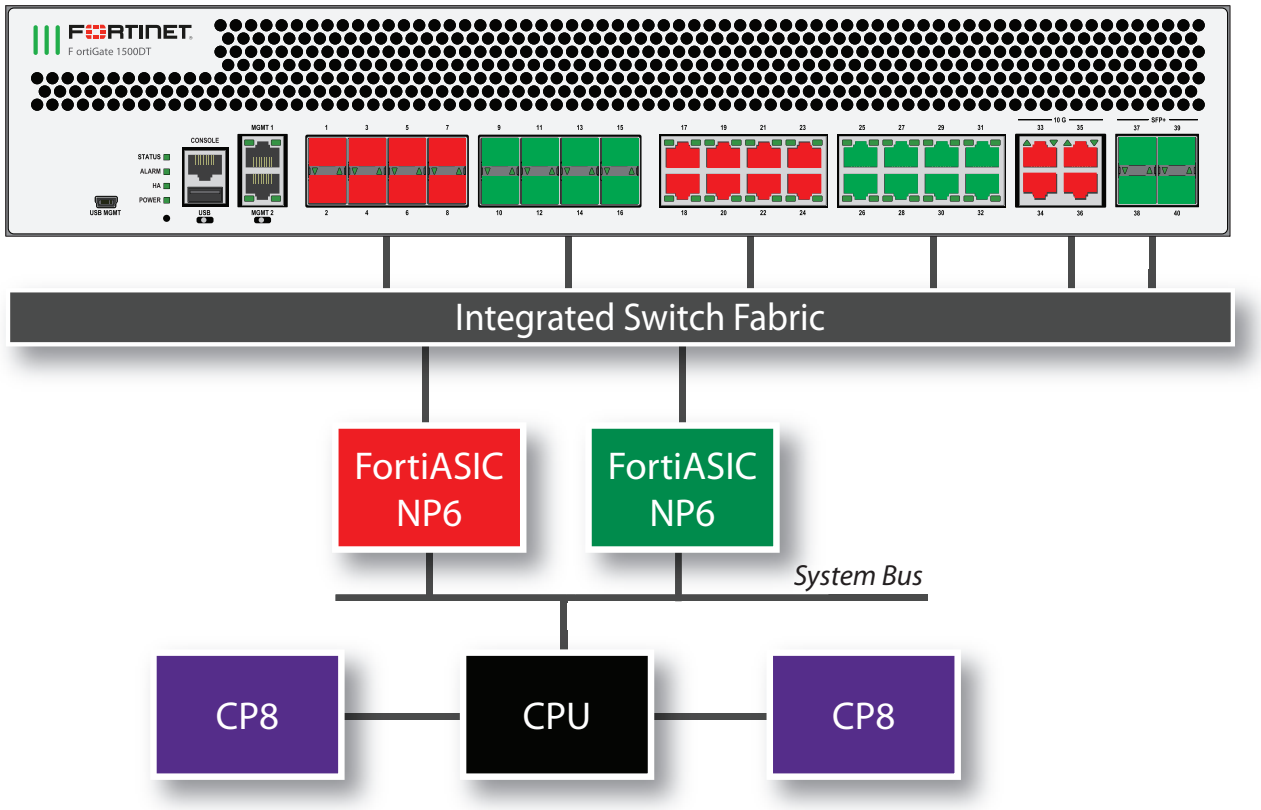
FortiGate-1500DT fast path architecture

The FortiGate-1500DT features two NP6 processors both connected to an integrated switch fabric. The FortiGate-1500DT has the same hardware configuration as the FortiGate-1500D, but with the addition of newer CPUs and DPDK technology that improves IPS performance.

The FortiGate-1500DT includes the following interfaces and NP6 processors:

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and four SFP+ 10Gb interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.



You can use the following diagnose command to display the FortiGate-1500DT NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

FortiGate-3700D fast path architecture

The FortiGate-3700D features four NP6 processors.The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700D fast path architecture.

FortiGate-3700D low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency that other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

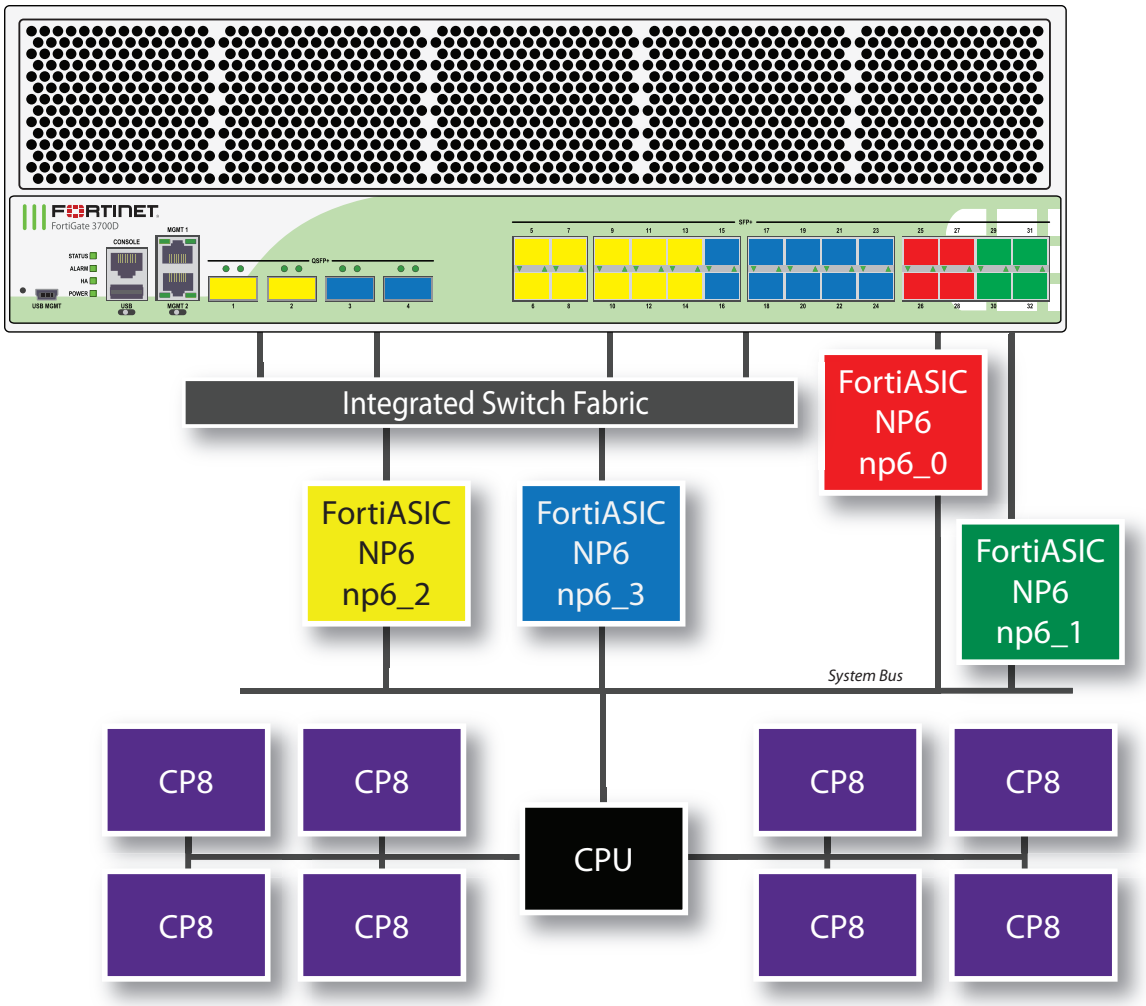
You can use the following command to turn on low latency mode for np6_0 and np6_1:

```
config system np6
   edit np6_0
      set low-latency-mode enable
   next
   edit np6_1
      set low-latency-mode enable
   end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700D has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).



You can use the following command to display the FortiGate-3700D NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6.

```

FortiGate-3700D normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

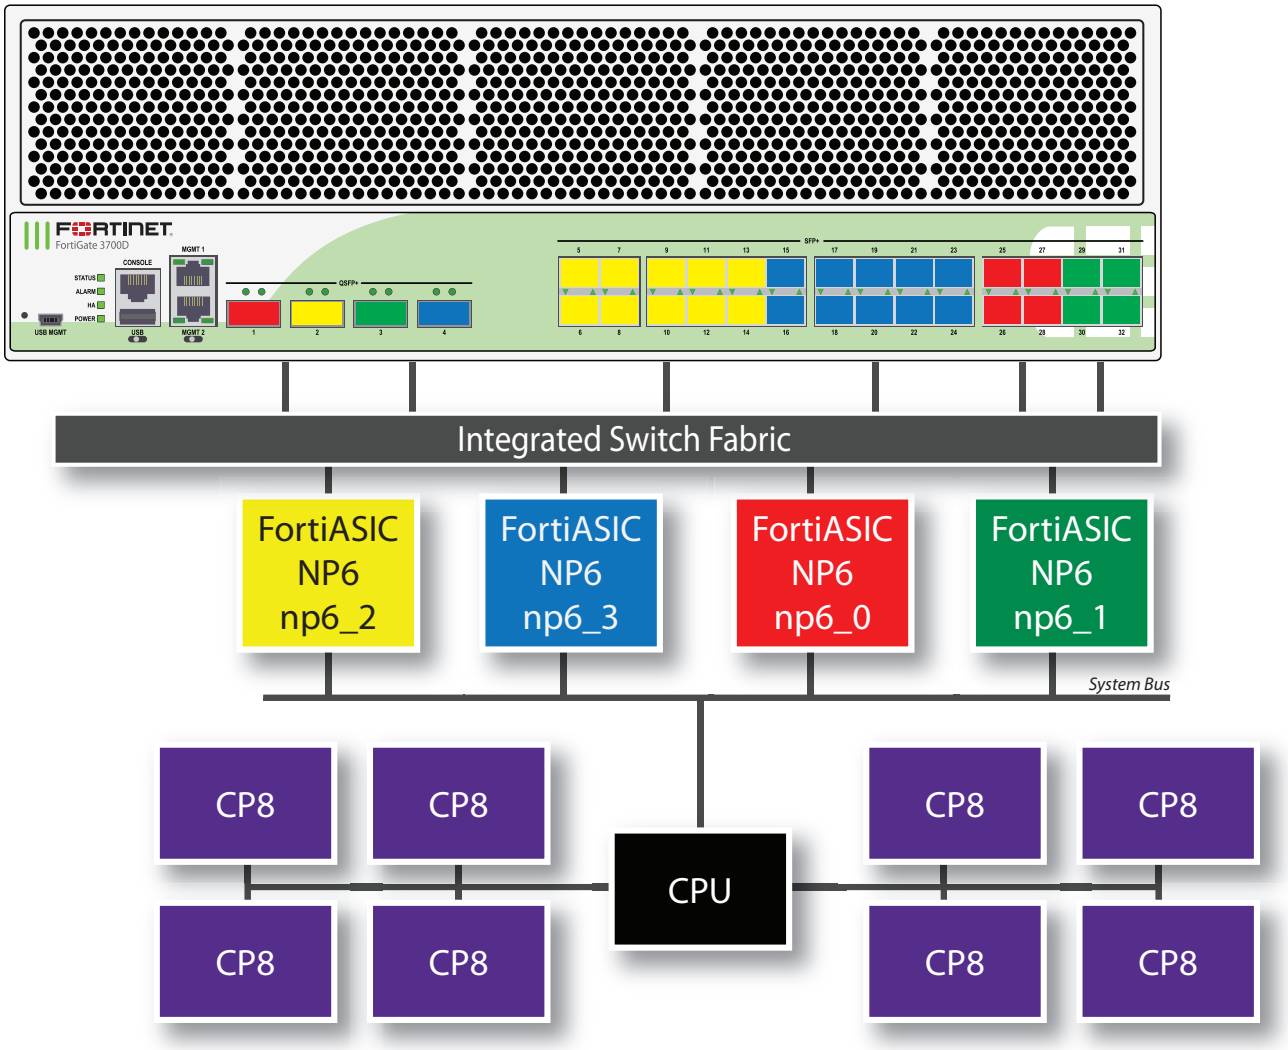
```
config system np6
   edit np6_0
      set low-latency-mode disable
   next
   edit np6_1
      set low-latency-mode disable
   end
```

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700D has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).

- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).



You can use the following command to display the FortiGate-3700D NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6.

```

FortiGate-3700DX fast path architecture

The FortiGate-3700DX features four NP6 processors.The first two NP6 processors (np6_0 and np6_1) can be configured for low latency operation. The low latency configuration changes the FortiGate-3700DX fast path architecture. The FortiGate-3700DX also includes two TP2 cards that are not supported by FortiOS 5.2.

FortiGate-3700DX low latency fast path architecture

Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700DX through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency that other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric (ISF).

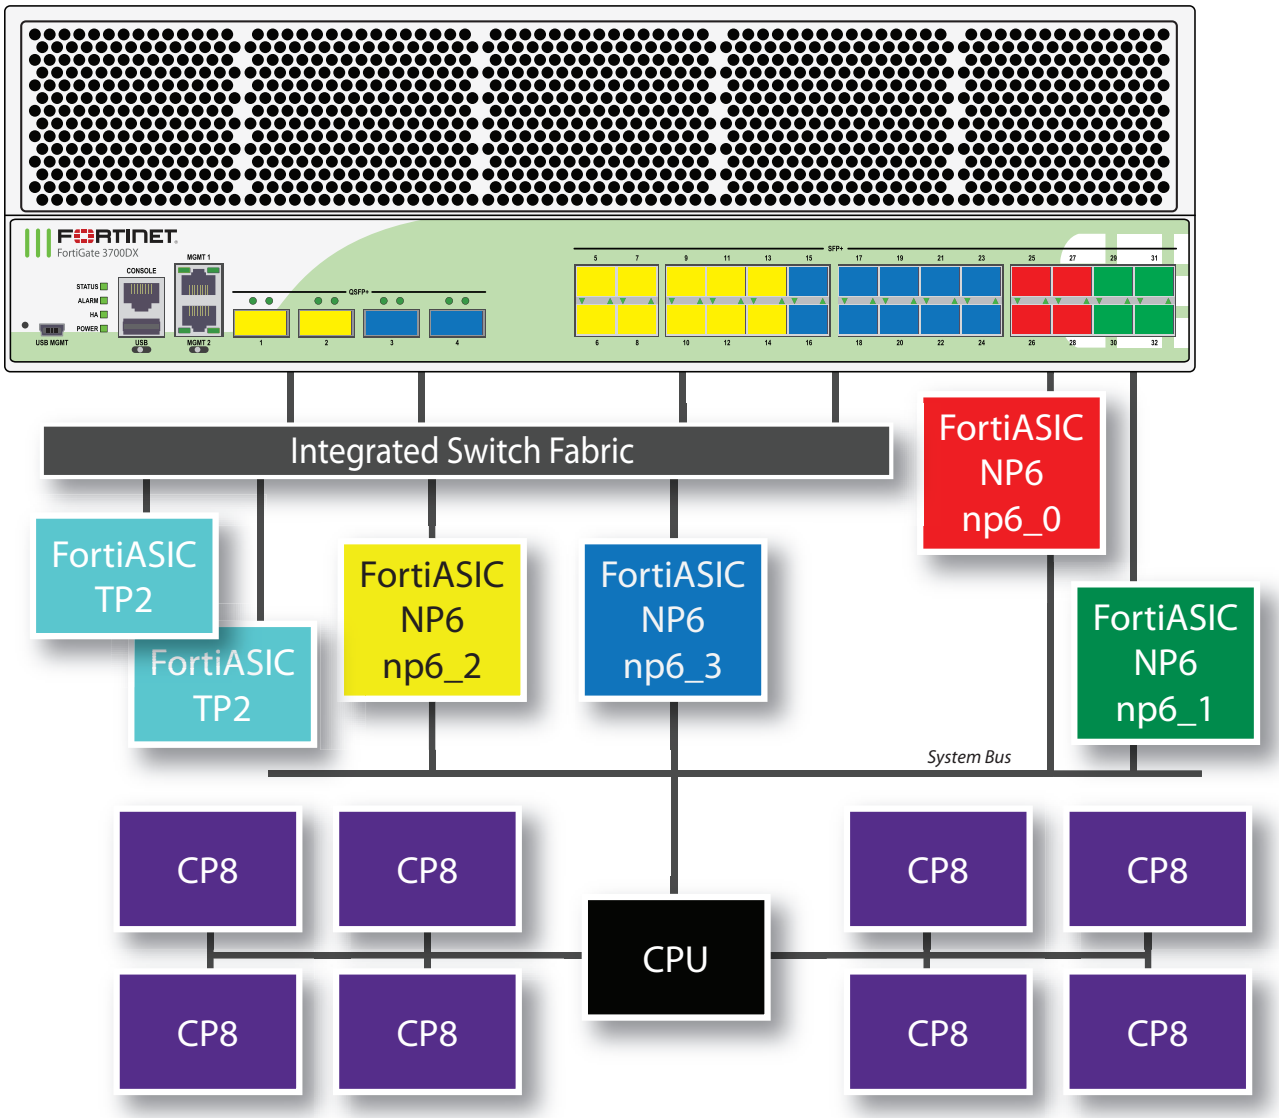
You can use the following command to turn on low latency mode for np6_0 and np6_1:

```
config system np6
  edit np6_0
    set low-latency-mode enable
  next
  edit np6_1
    set low-latency-mode enable
  end
```

You do not have to turn on low latency to both np6_0 and np6_1. If you turn on low latency for just one NP6, the other NP6 will still be mapped according to the normal latency configuration.

With low latency enabled for both np6_0 and np6_1 the FortiGate-3700DX has the following fastpath architecture:

- Four SFP+ 10Gb interfaces, port25 to port28, share connections to the first NP6 processor (np6_0) so sessions entering one of these ports and exiting through another will experience low latency
- Four SFP+ 10Gb interfaces, port29 to port32, share connections to the second NP6 processor (np6_1) so sessions entering one of these ports and exiting through another will experience low latency
- Ten SFP+ 10Gb interfaces, port5 to port14, and two 40Gb QSFP interfaces, port1 and port2, share connections to the third NP6 processor (np6_2).
- Ten SFP+ 10Gb interfaces, port15 to port24, and two 40Gb QSFP interfaces, port3 and port4, share connections to the fourth NP6 processor (np6_3).



You can use the following diagnose command to display the FortiGate-3700DX NP6 configuration. In this output example, the first two NP6s (np6_0 and np6_1) are configured for low latency. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6.

```

       3    port31  10G   No
------ ---- ------- ----- ----------
```

FortiGate-3700DX normal latency fast path architecture

You can use the following command to turn off low latency mode for np6_0 and np6_1:

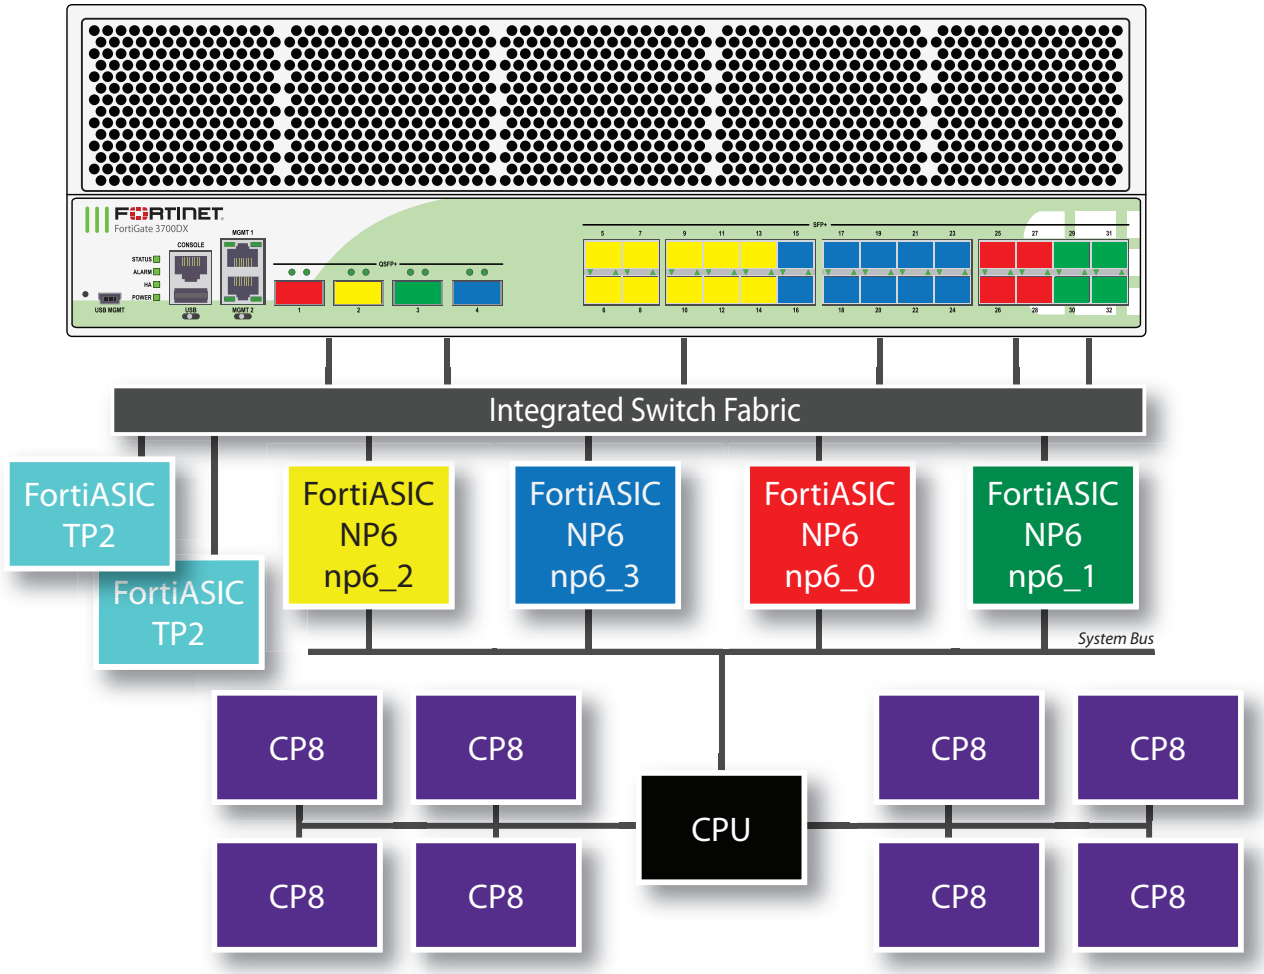
```
config system np6
   edit np6_0
      set low-latency-mode disable
   next
   edit np6_1
      set low-latency-mode disable
```

```
end
```

You do not have to turn off low latency to both np6_0 and np6_1. If you turn off low latency to just one NP6, the other NP6 will still be mapped according to the normal configuration.

In addition to turning off low latency, entering these commands also changes how ports are mapped to NP6s. Port1 is now mapped to np6_0 and port 3 is not mapped to np6_1. The FortiGate-3700DX has the following fastpath architecture:

- One 40Gb QSFP interface, port1, and four SFP+ 10Gb interfaces, port25 to port28 share connections to the first NP6 processor (np6_0).
- One 40Gb QSFP interface, port3, and four SFP+ 10Gb interfaces, port29 to port32 share connections to the second NP6 processor (np6_1).
- One 40Gb QSFP interface, port2 and ten SFP+ 10Gb interfaces, port5 to port14 share connections to the third NP6 processor (np6_2).
- One 40Gb QSFP interface, port4, and ten SFP+ 10Gb interfaces, port15 to port24 share connections to the fourth NP6 processor (np6_3).



You can use the following diagnose command to display the FortiGate-3700DX NP6 configuration with low latency turned off for np6_0 and np6_1. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3 and the interfaces (ports) connected to each NP6.

```

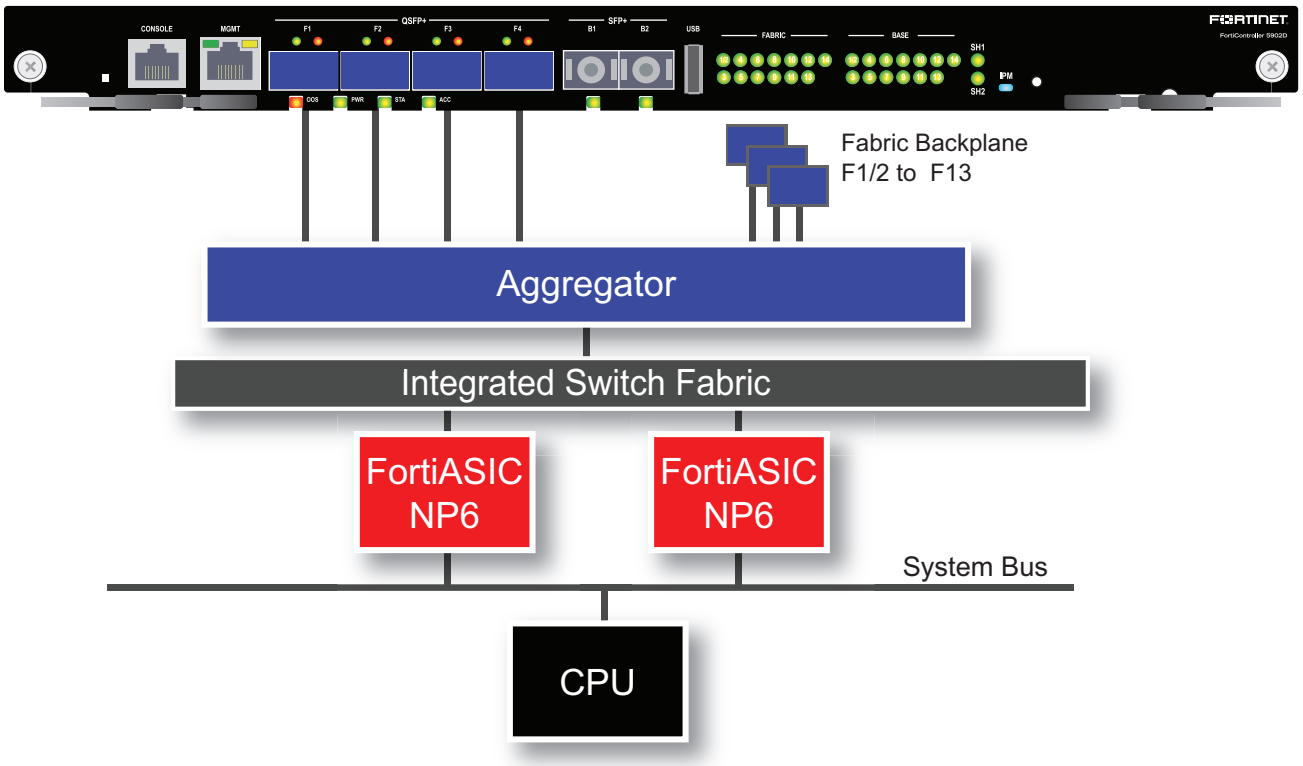
FortiController-5902D fast path architecture

The FortiController-5902D NP6 network processors and integrated switch fabric (ISF) provide hardware acceleration by offloading load balancing from the primary FortiController-5902D CPU. Network processors are especially useful for accelerating load balancing of TCP and UDP sessions.

The first packet of every new session is received by the primary FortiController-5902D and the primary FortiController-5902D uses its load balancing schedule to select the worker that will process the new session. This information is passed back to an NP6 network processor and all subsequent packets of the same sessions are offloaded to an NP6 network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the NP6 network processors resulting in a faster and more stable active-active cluster.

Traffic accepted by the FortiController-5902D F1 to F4 interfaces is that is processed by the primary FortiController-5902D is also be offloaded to the NP6 processors.

Individual FortiController-5902D interfaces are not mapped to NP6 processors. Instead an Aggregator connects the all fabric interfaces to the ISF and no special mapping is required for fastpath offloading.



NP6 content clustering mode interface mapping

FortiController-5902Ds run in content clustering mode and load balance sessions to FortiGate-5001D workers. Use the following command to enable content clustering:

```
config system elbc
   set mode content-cluster
   set inter-chassis-support enable
end
```

You can use the following command to display the content clustering FortiController-5902D NP6 configuration. The output shows that all ports are mapped to all NP6 processors.

```
diagose npu np6 port-list

NP4 Acceleration

NP4 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP4 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP4 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP4 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP4 processor plus the network processing load is removed from the CPU. In addition, the NP4 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP4 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP4. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP4s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP4s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements because traffic enters and exits on interfaces connected to the same ISF. Most FortiGate models with multiple NP4 processors connect all interfaces and NP4 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There is one limitation to keep in mind; the capacity of each NP4 processor. An individual NP4 processor has a capacity of 20 Gbps (10 Gbps ingress and 10 Gbps egress). Once an NP4 processor hits its limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP4 processors. To be able to do this you need to be aware of which interfaces connect to which NP4 processors and distribute incoming traffic accordingly.

Some FortiGate units contain one NP4 processor with all interfaces connected to it and to the ISF. As a result, offloading is supported for traffic between any pair of interfaces.

Some FortiGate units include NP4Lite processors. These network processors have the same functionality and limitations as NP4 processors but with about half the performance. NP4lite processors can be found in mid-range FortiGate models such as the FortiGate-200D and 240D.

Viewing your FortiGate's NP4 configuration

To list the NP4 network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu np4 list
```

The output lists the interfaces that have NP4 processors. For example, for a FortiGate-5001C:

```
get hardware npu np4 list
ID    Model         Slot       Interface
0     On-board                 port1 port2 port3 port4
                               fabric1 base1 npu0-vlink0 npu0-vlink1
1     On-board                 port5 port6 port7 port8
                               fabric2 base2 npu1-vlink0 npu1-vlink1
```

NP4lite CLI commands (disabling NP4Lite offloading)

If your FortiGate unit includes an NP4Lite processor the following commands will be available:

- Use the following command to disable or enable NP4Lite offloading. By default NP4lite offloading is enabled. If you want to disable NP4Lite offloading to diagnose a problem enter:

```
diagnose npu nplite fastpath disable
```

This command disables NP4Lite offloading until your FortiGate reboots. You can also re-enable offloading by entering the following command:

```
diagnose npu nplite fastpath enable
```

- NP4lite debug command. Use the following command to debug NP4Lite operation:

```
diagnose npl npl_debug {<parameters>}
```

Configuring NP4 traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

NP4 session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported)
- Layer 3 protocol must be IPv4
- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)
- Firewall policies must not include proxy-based security features (proxy-based virus scanning, proxy-based web filtering, DNS filtering, DLP, email filtering, VoIP, ICAP, or Proxy options).
- If the FortiGate supports NTurbo, firewall policies can include flow-based security features (IPS, Application Control, flow-based antivirus, or flow-based web filtering) .
- Origin must not be local host (the FortiGate unit)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable NP4 hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See Offloading NP4 anomaly detection on page 1234Offloading NP4 anomaly detection on page 1234

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.

- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP4.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

Increasing NP4 offloading capacity using link aggregation groups (LAGs)

NP4 processors can offload sessions received by interfaces in link aggregation groups (LAGs) (IEEE 802.3ad). A LAG combines more than one physical interface into a group that functions like a single interface with a higher capacity than a single physical interface. For example, you could use a LAG if you want to offload sessions on a 3 Gbps link by adding three 1Gbps interfaces to the same LAG.

All offloaded traffic types are supported by LAGs, including IPsec VPN traffic. Just like with normal interfaces, traffic accepted by a LAG is offloaded by the NP4 processor connected to the interfaces in the LAG that receive the traffic to be offloaded. If all interfaces in a LAG are connected to the same NP4 processor, traffic received by that LAG is offloaded by that NP4 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP4 processor.

If a FortiGate has two or more NP4 processors connected by an integrated switch fabric (ISF), you can use LAGs to increase offloading by sharing the traffic load across multiple NP4 processors. You do this by adding physical interfaces connected to different NP4 processors to the same LAG.

Adding a second NP4 processor to a LAG effectively doubles the offloading capacity of the LAG. Adding a third further increases offloading. The actual increase in offloading capacity may not actually be doubled by adding a second NP4 or tripled by adding a thrid. Traffic and load conditions and other factors may limit the actual offloading result.

The increase in offloading capacity offered by LAGs and multiple NP4s is supported by the ISF that allows multiple NP4 processors to share session information. On models that have more than one NP4 and no ISF, if you attempt to add interfaces connected to different NP4 processors to a LAG the system displays an error message.

There are also a few limitations to LAG NP4 offloading support for IPsec VPN:

- IPsec VPN anti-replay protection cannot be used if IPSec is configured on a LAG that has interfaces connected to multiple NP4 processors.
- Using a LAG connected to multiple NP4 processors for decrypting incoming IPsec VPN traffic may cause some of the incoming traffic to be decrypted by the CPU. So this configuration is not recommended since not all decryption is offloaded. (Using a LAG connected to multiple NP4 processors for encrypting outgoing IPsec VPN traffic is supported with no limitations.)
- Because the encrypted traffic for one IPsec VPN tunnel has the same 5-tuple, the traffic from one tunnel can only can be balanced to one interface in a LAG. This limits the maximum throughput for one IPsec VPN tunnel in an NP4 LAG group to 1Gbps.

NP4 traffic shaping offloading

Accelerated Traffic shaping is supported with the following limitations.

- NP4 processors support policy-based traffic shaping. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported.
- DSCP configurations are supported.
- Per-IP traffic shaping is supported.
- QoS in general is not supported.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling NP4 offloding. See Disabling NP offloading for firewall policies on page 1165.

NP4 IPsec VPN offloading

NP4 processors improve IPsec tunnel performance by offloading IPsec encryption and decryption.

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- Origin can be local host (the FortiGate unit)
- In Phase 1 configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor
- in Phase 2 configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
  - authentication must be MD5, SHA1, or null
  - if encryption is null, authentication must not also be null
  - if replay detection is enabled, `enc-offload-antireplay` must also be `enable` in the CLI

If replay detection is enabled in the Phase 2 configuration, you can enable or disable IPsec encryption and decryption offloading from the CLI. Performance varies by those CLI options and the percentage of packets requiring encryption or decryption. For details, see NP4 IPsec VPN offloading on page 1225

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase 1 negotiations to establish the security association (SA). The SA includes cryptographic

processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
  - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
  - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources
- IPsec encryption offload
  - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
  - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

NP4 IPsec VPN offloading configuration example

Hardware accelerated IPsec processing, involving either partial or full offloading, can be achieved in either tunnel or interface mode IPsec configurations.

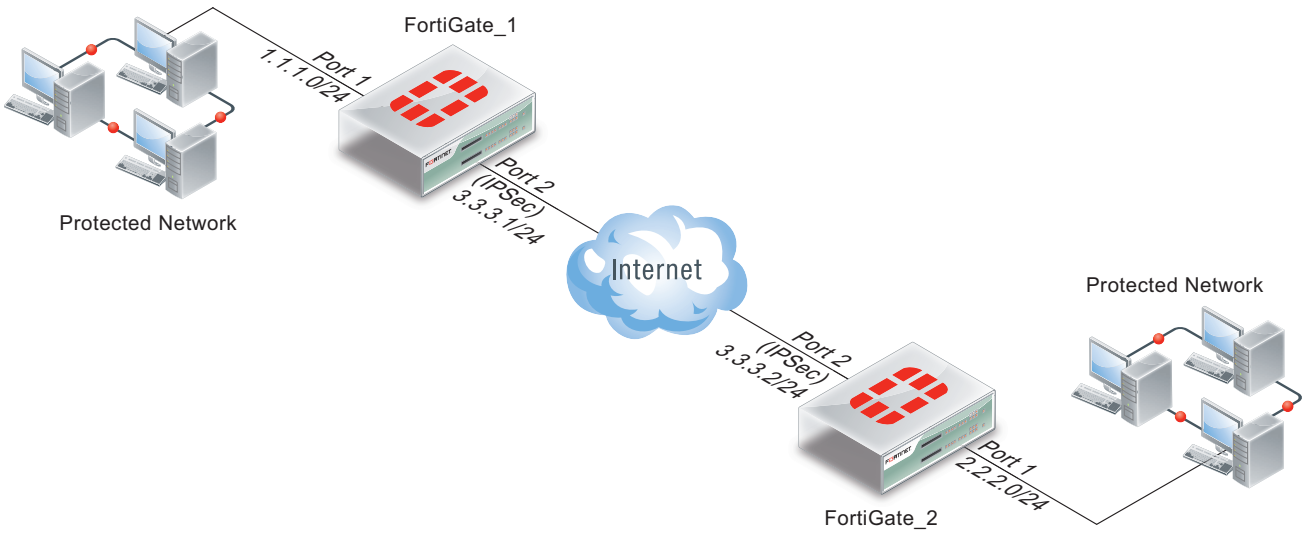
To achieve offloading for both encryption and decryption:

- In Phase 1 configuration's Advanced section, Local Gateway IP must be specified as an IP address of a network interface associated with a port attached to a network processor. (In other words, if Phase 1's Local Gateway IP is Main Interface IP, or is specified as an IP address that is not associated with a network interface associated with a port attached to a network processor, IPsec network processing is not offloaded.)
- In Phase 2 configuration's P2 Proposal section, if the checkbox "Enable replay detection" is enabled, `enc-offload-antireplay` and `dec-offload-antireplay` must be set to `enable` in the CLI.
- `offload-ipsec-host` must be set to `enable` in the CLI.

This section contains example IPsec configurations whose IPsec encryption and decryption processing is hardware accelerated by an NP4 unit contained in a FortiGate-5001B at both ends of the VPN tunnel.

Hardware accelerated IPsec VPN does not require both tunnel endpoints to have the same network processor model. However, if hardware is not symmetrical, the packet forwarding rate is limited by the slower side.

Example network topology for offloaded IPsec processing



Example ports and IP addresses for offloaded IPsec processing

	FortiGate_1		FortiGate_2	
	Port	**IP**	**Port**	**IP**
IPsec tunnel	FortiGate-5001B port 2	3.3.3.1/24	FortiGate-5001B port 2	3.3.3.2/24
Protected network	FortiGate-5001B port 1	1.1.1.0/24	FortiGate-5001B port 1	2.2.2.0/24

Accelerated policy mode IPsec configuration

The following steps create a hardware accelerated policy mode IPsec tunnel between two FortiGate-5001B units, each containing two NP4 processors, the first of which will be used.

To configure hardware accelerated policy mode IPsec

1. On FortiGate_1, go to **VPN > IPsec > Auto Key (IKE)**.
2. Configure Phase 1.
   For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.
   Select **Advanced**. In the Local Gateway IP section, select **Specify** and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module port 2.
3. Configure Phase 2.

4. Select **Enable replay detection**.
5. Use the following command to enable offloading antireplay packets:

```
config system npu
   set enc-offload-antireplay enable
end
```

   For details on encryption and decryption offloading options available in the CLI, see"Configuring NP accelerated VPN encryption/decryption offloading".

6. Go to **Policy > Policy > Policy**.
7. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-5001B ports 1 and 2.
8. Go to **Router > Static > Static Route**.
9. Configure a static route to route traffic destined for FortiGate_2's protected network to VPN IP address of FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-5001B port2.
   You can also configure the static route using the following CLI command:

```
config router static
   edit 2
      set device "AMC-SW1/2"
      set dst 2.2.2.0 255.255.255.0
      set gateway 3.3.3.2
   end
```

10. On FortiGate_2, go to **VPN > IPsec > Auto Key (IKE)**.
11. Configure Phase 1.
    For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.
    Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's port2.
12. Configure Phase 2.
13. Select **Enable replay detection**.
14. Use the following command to enable offloading antireplay packets:

```
config system npu
   set enc-offload-antireplay enable
end
```

    For details on encryption and decryption offloading options available in the CLI, see Configuring NP accelerated IPsec VPN encryption/decryption offloading on page 1163.

15. Go to **Policy > Policy > Policy**.
16. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 9 to traffic between FortiGate-5001B ports 1 and 2.
17. Go to **Router > Static > Static Route**.
18. Configure a static route to route traffic destined for FortiGate_1's protected network to VPN IP address of FortiGate_1's VPN gateway, 3.3.3.1, through the FortiGate-5001B port2.
    You can also configure the static route using the following CLI commands:

```
config router static
   edit 2
      set device "AMC-SW1/2"
      set dst 1.1.1.0 255.255.255.0
      set gateway 3.3.3.1
   end
```

19. Activate the IPsec tunnel by sending traffic between the two protected networks.
    To verify tunnel activation, go to **VPN > Monitor > IPsec Monitor**.

Accelerated interface mode IPsec configuration

The following steps create a hardware accelerated interface mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated interface mode IPsec

1. On FortiGate_1, go to **VPN > IPsec > Auto Key (IKE)**.
2. Configure Phase 1.
   For interface mode IPsec and for hardware acceleration, the following settings are required.
   - Select Advanced.
   - Enable the checkbox “Enable IPsec Interface Mode.”
   - In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2’s port 2.
3. Configure Phase 2.
4. Select **Enable replay detection**.
5. Use the following command to enable offloading antireplay packets:

```
config system npu
   set enc-offload-antireplay enable
end
```

   For details on encryption and decryption offloading options available in the CLI, see "Configuring NP accelerated VPN encryption/decryption offloading".

6. Go to **Policy > Policy > Policy**.
7. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.
8. Go to **Router > Static > Static Route**.
9. Configure a static route to route traffic destined for FortiGate_2’s protected network to the Phase 1 IPsec device, `FGT_1_IPsec`.
   You can also configure the static route using the following CLI commands:

```
config router static
   edit 2
      set device "FGT_1_IPsec"
      set dst 2.2.2.0 255.255.255.0
   end
```

10. On FortiGate_2, go to **VPN > IPsec > Auto Key (IKE)**.
11. Configure Phase 1.
    For interface mode IPsec and for hardware acceleration, the following settings are required.
    - Enable the checkbox “Enable IPsec Interface Mode.”
    - In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1’s FortiGate-5001B port 2.
12. Configure Phase 2.
13. Select **Enable replay detection**.
14. Use the following command to enable offloading antireplay packets:

```
config system npu
```

```
    set enc-offload-antireplay enable
  end
```

For details on encryption and decryption offloading options available in the CLI, see " Hardware acceleration overview" on page 1155.

15. Go to **Policy > Policy > Policy**.
16. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 9 to traffic leaving from or arriving on FortiGate-5001B port 1.
17. Go to **Router > Static > Static Route**.
18. Configure a static route to route traffic destined for FortiGate_1's protected network to the Phase 1 IPsec device, `FGT_2_IPsec`.
    You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
    next
  end
```

19. Activate the IPsec tunnel by sending traffic between the two protected networks.
    To verify tunnel activation, go to **VPN > Monitor > IPsec Monitor**.

Configuring Inter-VDOM link acceleration with NP4 processors

FortiGate units with NP4 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

Traffic is blocked if you enable IPS for traffic passing over inter-VDOM links if that traffic is being offloaded by an NP4 processor.If you disable NP4 offloading traffic will be allowed to flow. You can disable offloading in individual firewall policies by disabling `auto-asic-offload` for individual policies. You can also use the following command to disable all IPS offloading

```
config ips global
  set np-accel-mode {none | basic}
  set cp-accel-mode {none | basic | advanced}
end
```

- For a FortiGate unit with two NP4 processors there are also two inter-VDOM links, each with two interfaces:
  - **npu0-vlink:**
    npu0-vlink0
    npu0-vlink1
  - **npu1-vlink:**
    npu1-vlink0
    npu1-vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP4 interfaces, enter the following CLI command (output shown for a FortiGate-5001B):

```
get hardware npu np4 list
ID    Model         Slot       Interface
0     On-board                 port1 port2 port3 port4
                               fabric1 base1 npu0-vlink0 npu0-vlink1
1     On-board                 port5 port6 port7 port8
```

```
fabric2 base2 npu1-vlink0 npu1-vlink1
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in a pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to **System > Network > Interfaces** and edit the **npu0-vlink1** interface and set the **Virtual Domain** to **New-VDOM**.

This results in an inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
   edit npu0-vlink1
      set vdom New-VDOM
end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to **System > Network > Interfaces** and select **Create New** to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0-vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0-vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
   edit Marketing-link
      set vdom Marketing
      set ip 172.20.120.12/24
      set interface npu0-vlink0
      set vlanid 100
   next
   edit Engineering-link
      set vdom Engineering
      set ip 172.20.120.22/24
      set interface npu0-vlink1
      set vlanid 100
```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP4 processor.

```
diagnose ip address list
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2
IP=172.20.120.12->172.20.120.12/255.255.255.0 index=55 devname=IVL-VLAN1_ROOT
IP=172.20.120.22->172.20.120.22/255.255.255.0 index=56 devname=IVL-VLAN1_VDOM1

Offloading NP4 anomaly detection

Network interfaces associated with a port attached to an NP4 processor can be configured to offload anomaly checking to the NP4 processor. This anomaly checking happens before other offloading and separately from DoS policy anomaly checking. Using the following command, each FortiGate interface can have a different anomaly checking configuration even if they are connected to the same NP4 processor.

The options available for this command apply anomaly checking for NP4 sessions in the same way as the command descrbed in Configuring individual NP6 processors on page 1178 applies anomaly checking for for NP6 sessions.

```
config system interface
   edit <port-name>
      set fp-anomaly <anomalies>
   end
```

where `<anomalies>` can be one, more than one or all of the following:

Anomaly	Description
drop_icmp_frag	Drop ICMP fragments to pass.
drop_icmpland	Drop ICMP Land.
drop_ipland	Drop IP Land.
drop_iplsrr	Drop IP with Loose Source Record Route option.
drop_iprr	Drop IP with Record Route option.
drop_ipsecurity	Drop IP with Security option.
drop_ipssrr	Drop IP with Strict Source Record Route option.
drop_ipstream	Drop IP with Stream option.
drop_iptimestamp	Drop IP with Timestamp option.
drop_ipunknown_option	Drop IP with malformed option.
drop_ipunknown_prot	Drop IP with Unknown protocol.
drop_tcp_fin_noack	Drop TCP FIN with no ACT flag set to pass.
drop_tcp_no_flag	Drop TCP with no flag set to pass.
drop_tcpland	Drop TCP Land.
drop_udpland	Drop UDP Land.
drop_winnuke	Drop TCP WinNuke.
pass_icmp_frag	Allow ICMP fragments to pass.
pass_icmpland	Allow ICMP Land to pass.
pass_ipland	Allow IP land to pass.
pass_iplsrr	Allow IP with Loose Source Record Route option to pass.
pass_iprr	Allow IP with Record Route option to pass.
pass_ipsecurity	Allow IP with Security option to pass.
pass_ipssrr	Allow IP with Strict Source Record Route option to pass.

Anomaly	Description
pass_ipstream	Allow IP with Stream option to pass.
pass_iptimestamp	Allow IP with Timestamp option to pass.
pass_ipunknown_option	Allow IP with malformed option to pass.
pass_ipunknown_prot	Allow IP with Unknown protocol to pass.
pass_tcp_fin_noack	Allow TCP FIN with no ACT flag set to pass.
pass_tcp_no_flag	Allow TCP with no flag set to pass.
pass_tcpland	Allow TCP Land to pass.
pass_udpland	Allow UDP Land to pass.
pass_winnuke	Allow TCP WinNuke to pass.

Example

You might configure an NP4 to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

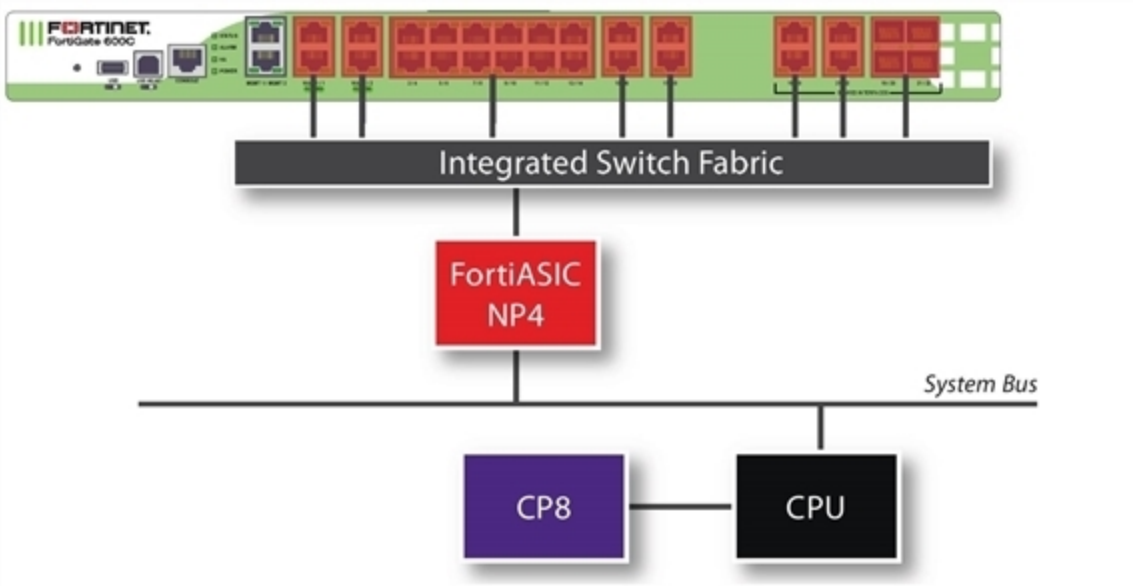
```
config system interface
   edit port1
      set fp-anomaly drop_winnuke drop_ipunknown_prot pass_iptimestamp
   end
```

FortiGate NP4 architectures

This chapter shows the NP4 architecture for the all FortiGate units and modules that include NP4 processors.

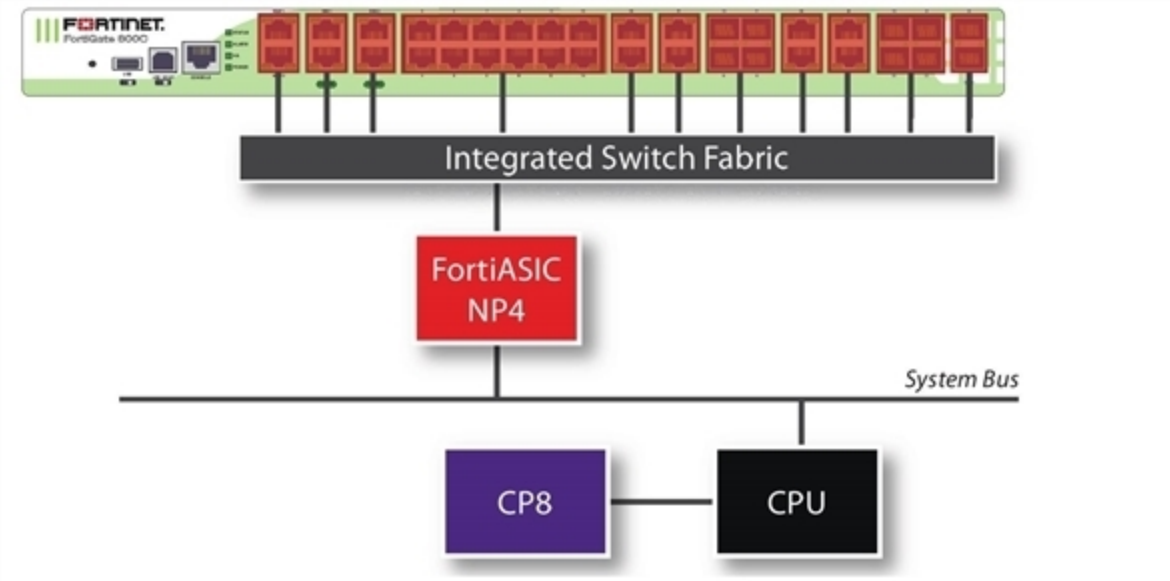
FortiGate-600C

The FortiGate-600C features one NP4 processor. All the ports are connected to this NP4 over the Integrated Switch Fabric. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are four 1Gb SFP interface ports duplicating the port19-port22 connections.



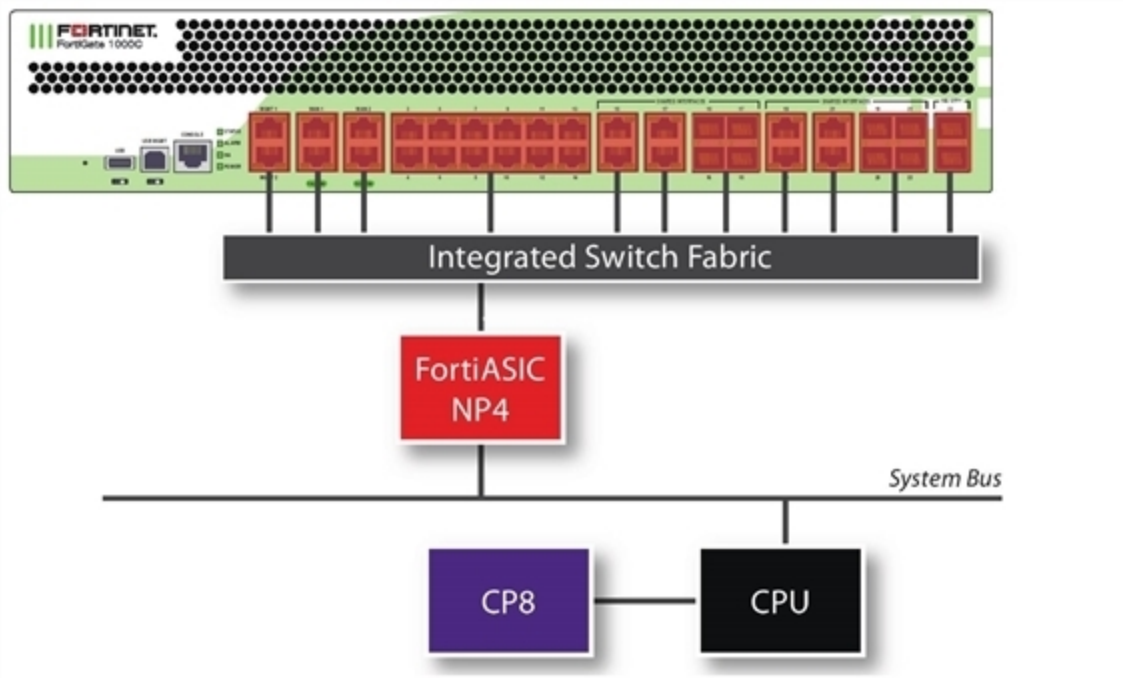
FortiGate-800C

The FortiGate-800C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.



FortiGate-1000C

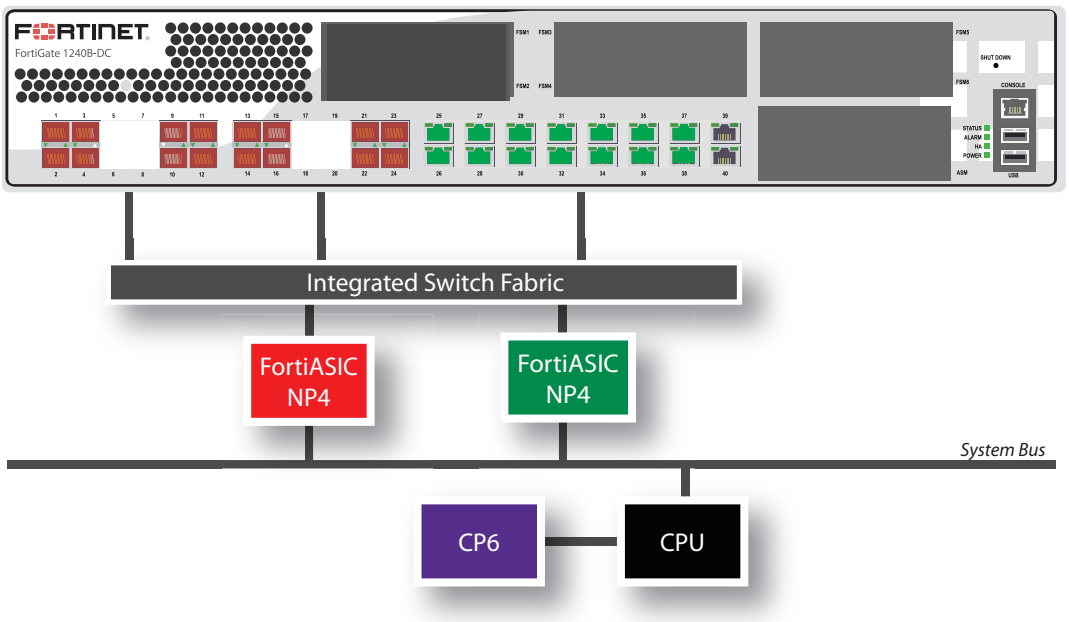
The FortiGate-1000C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.



FortiGate-1240B

The FortiGate-1240B features two NP4 processors:

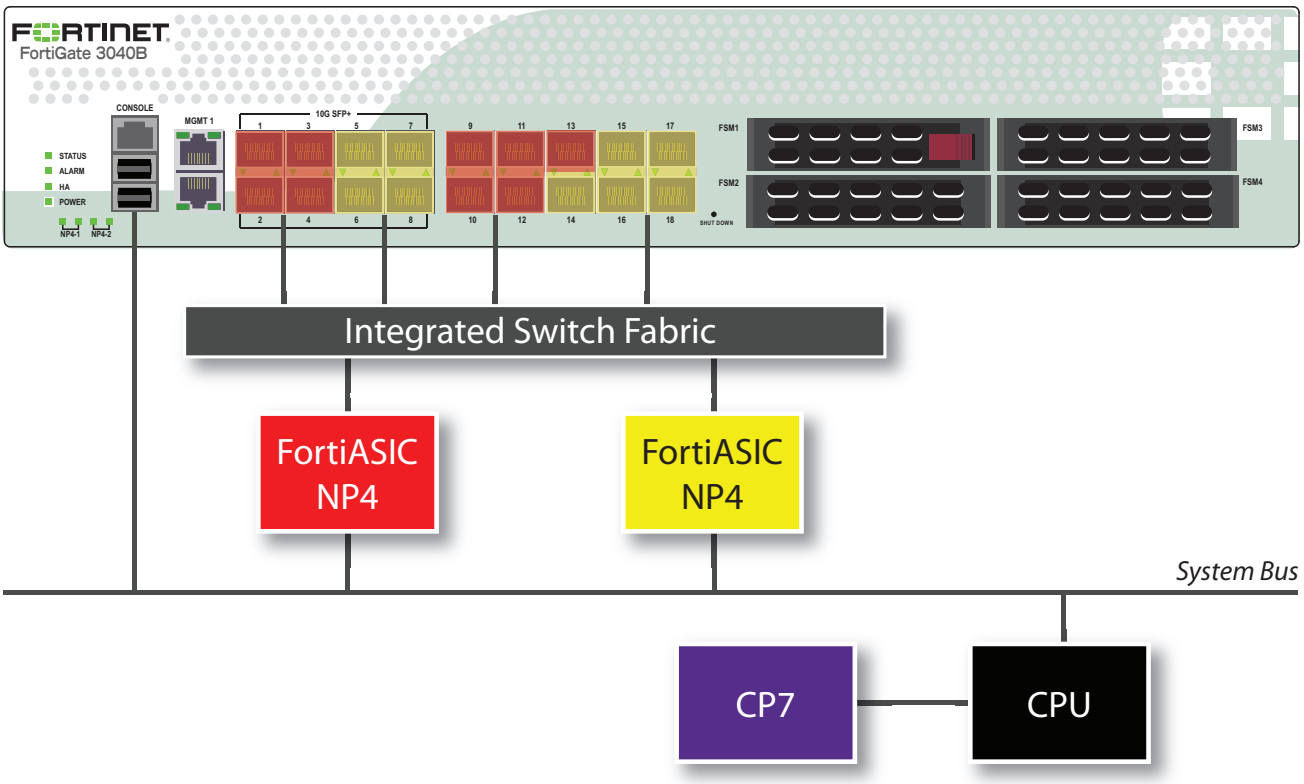
- Port1 to port24 are 1Gb SFP interfaces connected to one NP4 processor.
- Port25 to port38 are RJ-45 ethernet ports, connected to the other NP4 processor.
- Port39 and port40 are not connected to an NP4 processor.



FortiGate-3040B

The FortiGate-3040B features two NP4 processors:

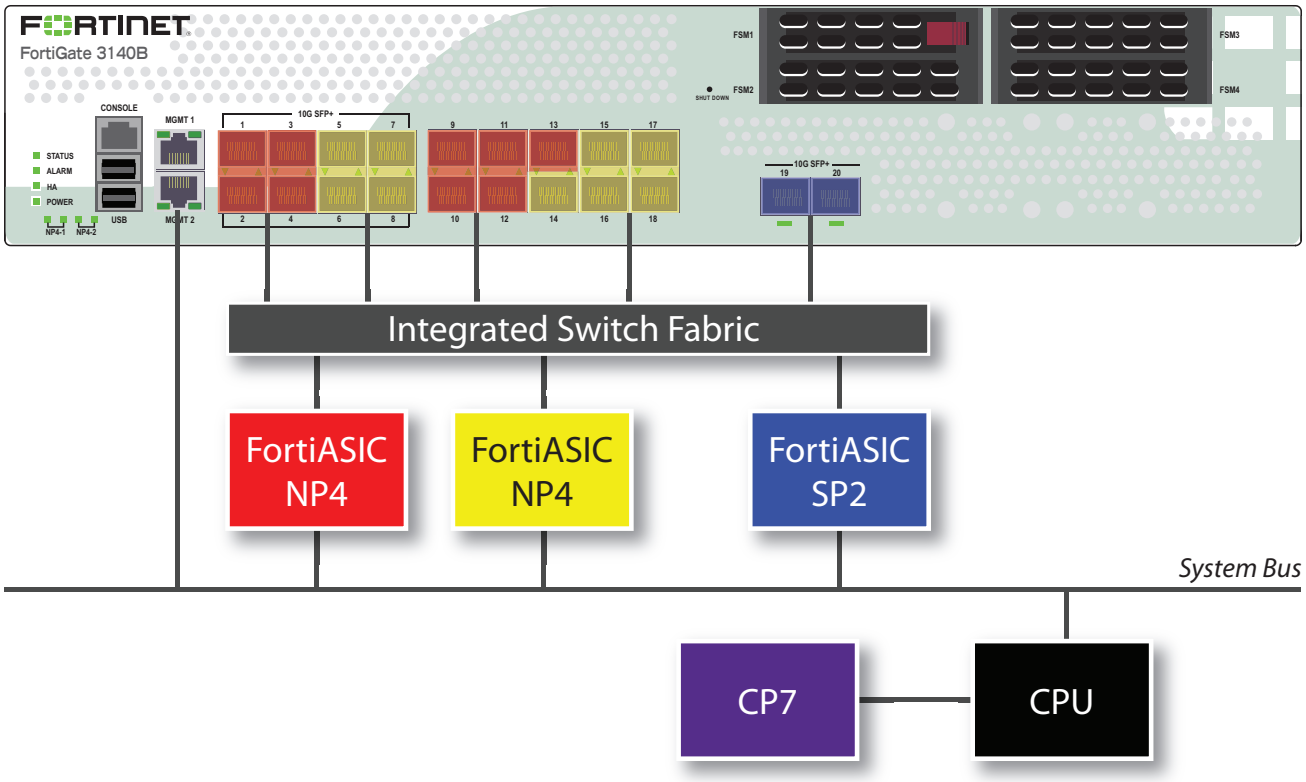
- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.



FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor:

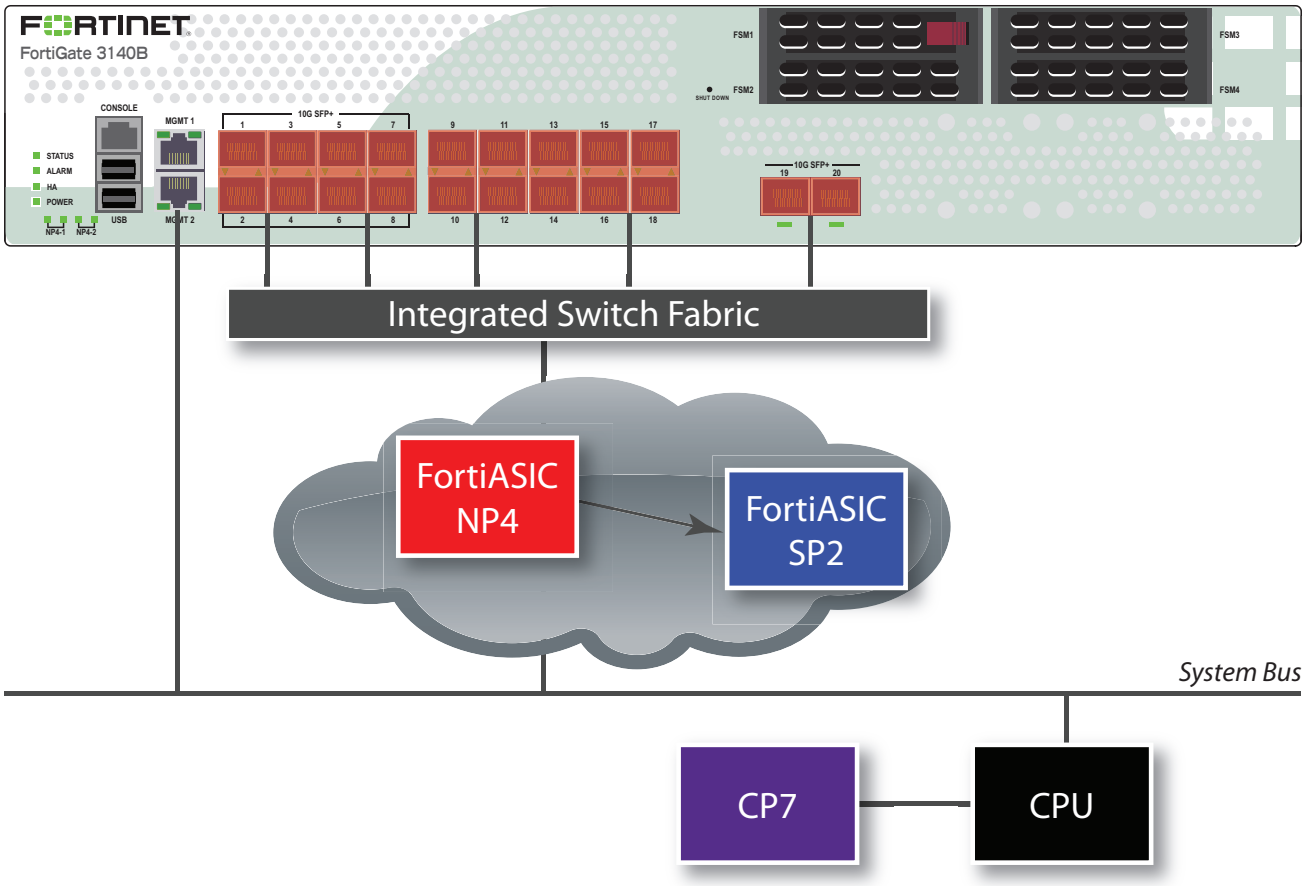
- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10Gb interfaces, port19 and port20, share connections to the SP2 processor.



FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.



To enable this feature, issue this CLI command.

```
config system global
   set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

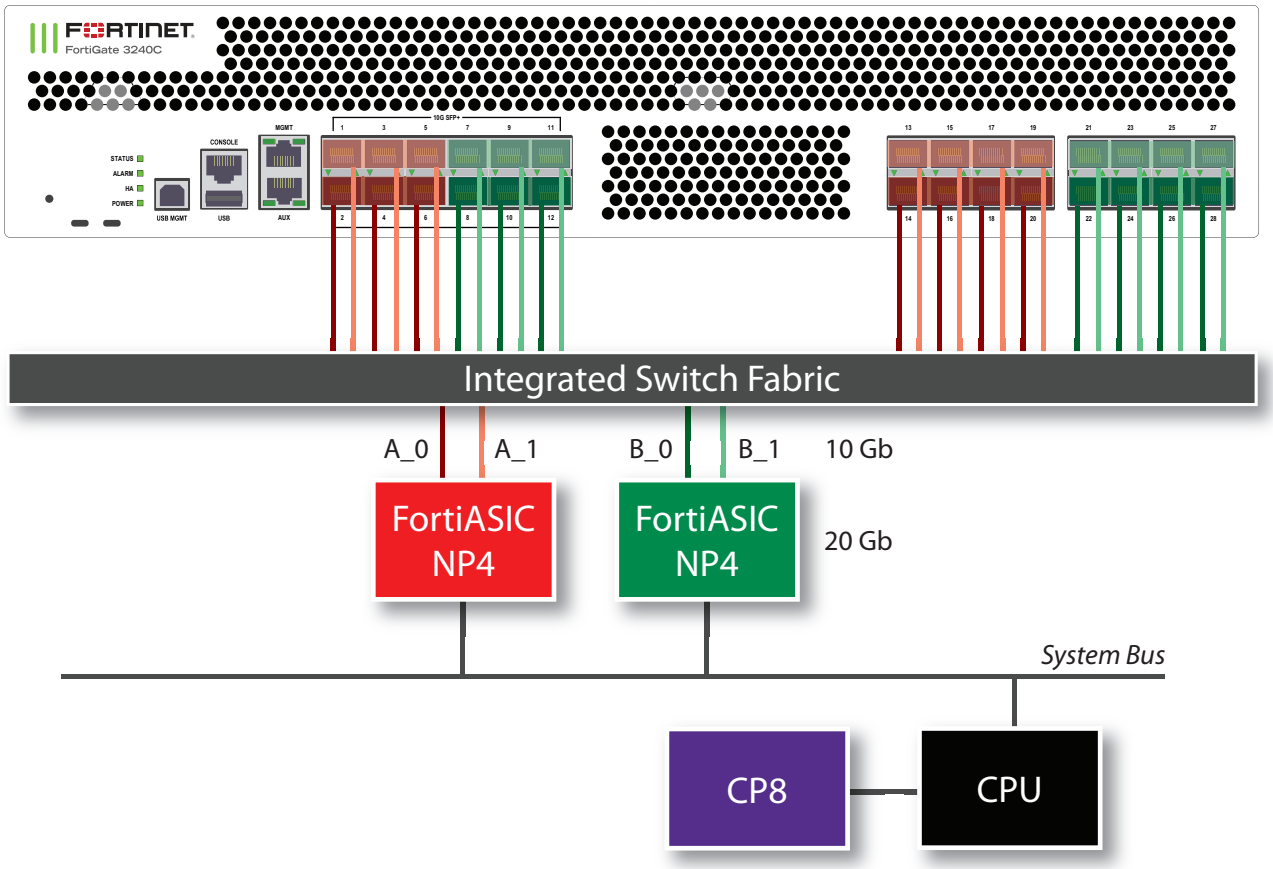
```
config system global
   set sp-load-balance disable
end
```

FortiGate-3240C

The FortiGate-3240C features two NP4 processors:

- The 10Gb interfaces, port1 through port6, and the 1Gb interfaces, port13 through port20, share connections to one NP4 processor.
- The 10Gb interfaces, port7 through port12, and the 1Gb interfaces, port21 through port28, share connections to the other NP4 processor.

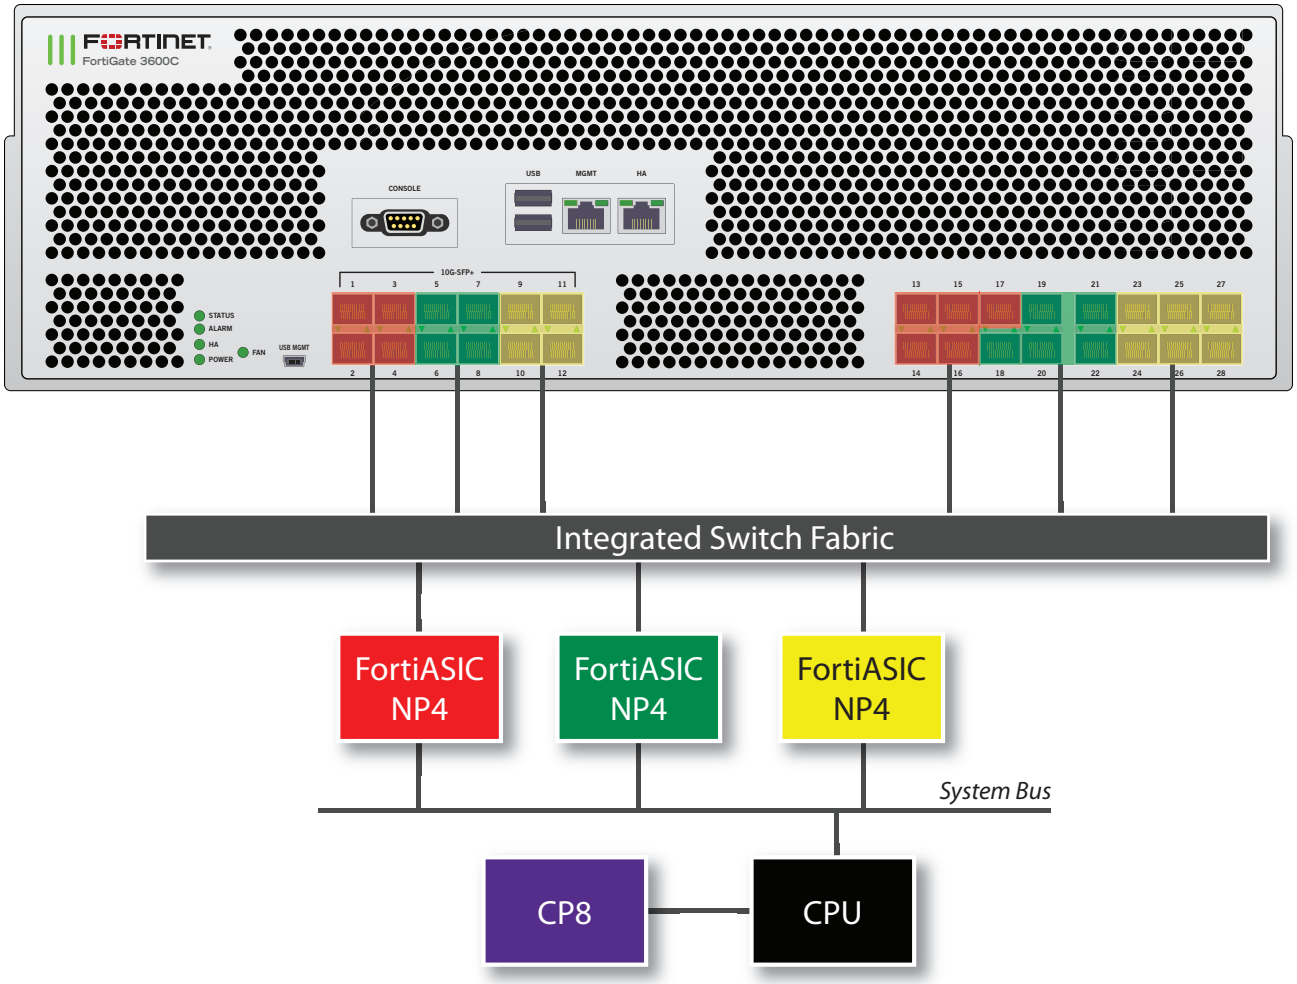
In addition to the ports being divided between the two NP4 processors, they are further divided between the two connections to each processor. Each NP4 can process 20 Gb of network traffic per second and each of two connections to each NP4 can move 10Gb of data to the processor per second, so the ideal configuration would have no more than 10 Gb of network traffic to each connection of each NP4 at any time.



FortiGate-3600C

The FortiGate-3600C features three NP4 processors:

- The 10Gb interfaces, port1-port4, and the 1Gb interfaces, port13-port17, share connections to one NP4 processor.
- The 10Gb interfaces, port5-port8, and the 1Gb interfaces, port18-port22 share connections to the second NP4 processor.
- The 10Gb interfaces, port9-port12, and the 1Gb interfaces, port23-port28 share connections to the third NP4 processor.



FortiGate-3600C XAUI interfaces

The FortiGate-3600C uses XAUI links for communication between physical Ethernet ports and the integrated switch fabric.

Each XAUI link has a maximum bandwidth of 10-Gigabits. The reason you may need to know about the XAUI link in NP4 configurations is because of this 10-Gigabit limit. Because of this limitation, the total amount of data processed by all Ethernet interfaces connected to an XAUI link cannot exceed 10 gigabits. In some cases this may limit the amount of bandwidth that the FortiGate can process.

Each NP4 processor connects to the integrated switch fabric through two XAUI links: XAUI0 and XAUI1. All of the odd numbered Ethernet interfaces use XAU0 and all of the even numbered interfaces use XAUI1:

NPU1

XAUI0 = port1,port3,port13, port15, port17

XAUI1 = port2, port4, port14, port16

NPU2

XAUI0 = port5, port7, port18, port20, port22

XAUI1 = port6, port8, port19, port21

NPU3

XAUI0 = port9, port11, port23, port25, port27

XAUI1 = port10, port12, port24, port26, port28

Usually you do not have to be concerned about XAUI link mapping. However, if a FortiGate-3600C NP4 interface is processing a very high amount of traffic you should distribute that traffic among both of the XAUI links connected to it. So if you have a very high volume of traffic flowing between two networks you should connect both networks to the same NP4 processor but to different XAUI links. For example, you could connect one network to Etherent port5 and the other network to Ethernet port6. In this configuration, the second NP4 processor would handle traffic acceleration and both XAUI links would be processing traffic.

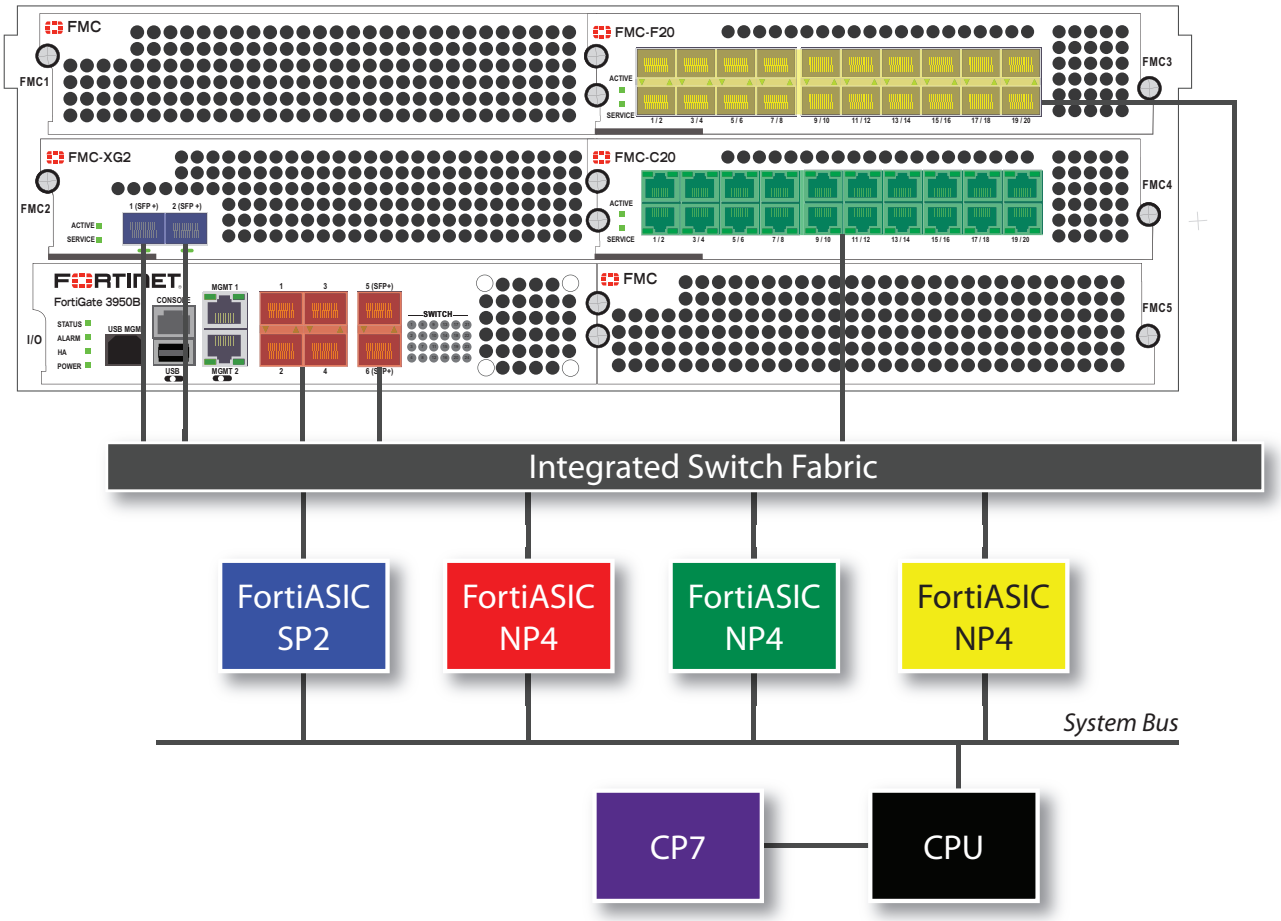
FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor. The 1Gb SPF interfaces, port1, port2, port3, port4, and the 10Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. The diagram below shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one SP2 processor. The 10Gb SPF+ interfaces, port1 and port2, share connections to the processor.
- The FMC-F20 has one NP4 processor and the twenty 1Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.

- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.



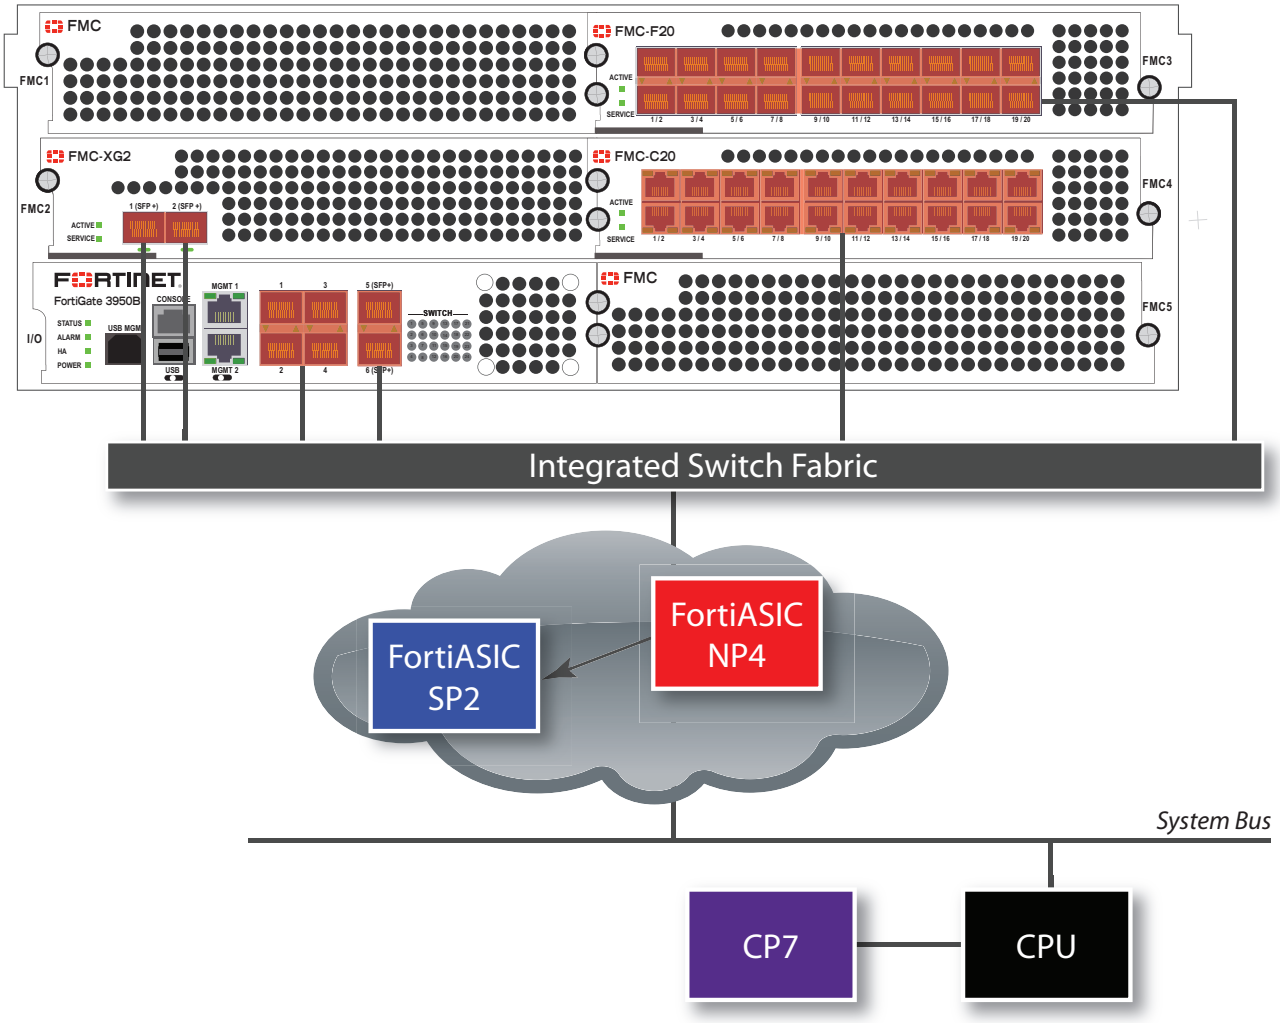
FortiGate-3950B and FortiGate-3951B — load balance mode

Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

The FortiGate-3950B in load balance mode



To enable this feature, issue this CLI command.

```
config system global
```

```
    set sp-load-balance enable
end
```

The FortiGate unit will then restart.

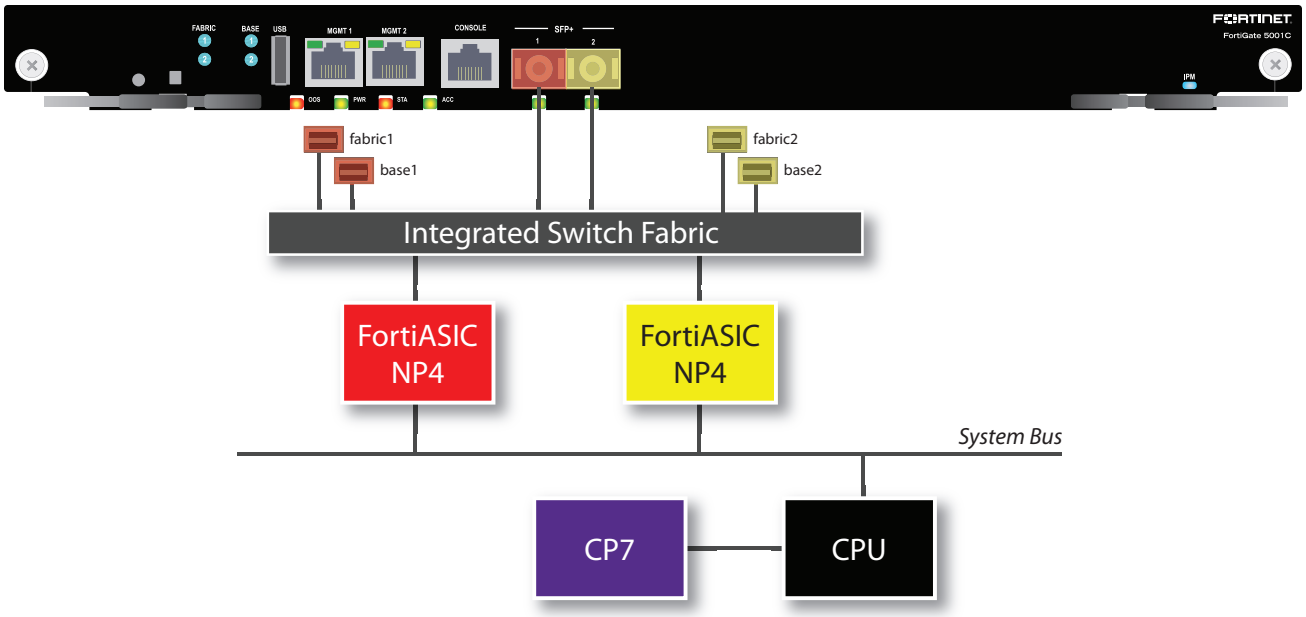
To return to the default mode, issue this CLI command.

```
config system global
    set sp-load-balance disable
end
```

FortiGate-5001C

The FortiGate-5001C board includes two NP4 processors connected to an integrated switch fabric:

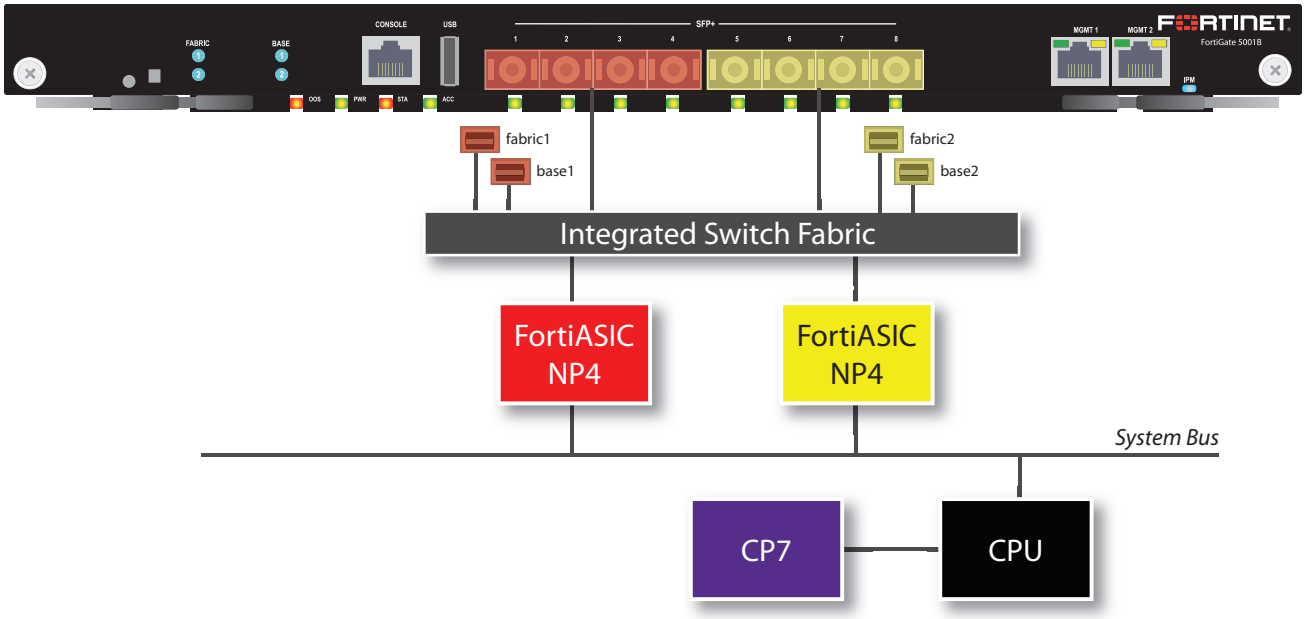
- The port1, fabric1, and base1 interfaces are connected to one NP4 processor.
- The port2, fabric2, and base2 interfaces are connected to the other NP4 processor.



FortiGate-5001B

The FortiGate-5001B board includes two NP4 connected to an integrated switch fabric.

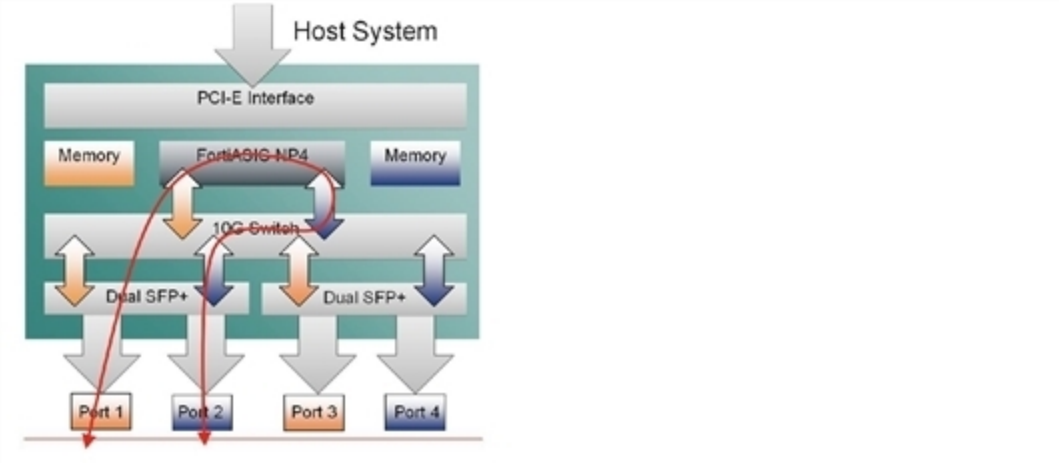
- The port1, port2, port3, port4, fabric1 and base1 interfaces are connected to one NP4 processor.
- The port5, port6, port7, port8, fabric2 and base2 interfaces are connected to the other NP4 processor.



Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10Gb/s ports, but the NP4 processor it contains has only two 10Gb/s ports. The external ports you use are important to optimize the SP for your application.

ADM-XD4 mapping mode



Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

Hardware acceleration diagnose commands

This section describes some diagnose commands you can use to display useful information about sessions processed by NP6 and other NPx processors.

diagnose sys session/session6 list (IPv4, IP6, NAT46, NAT64, and IPsec session information)

Display information about the IPv4, IPv6, NAT46, NAT64 and IPsec sessions being processed by NPx processors. The command output includes the following:

- `offload=1/1` for NP1(FA1) sessions.
- `offload=2/2` for NP1(FA2) sessions.
- `offload=3/3` for NP2 sessions.
- `offload=4/4` for NP4 sessions.
- `offload=5/5` for XLR sessions.
- `offload=6/6` for Nplite/NP4lite sessions.
- `offload=7/7` for XLP sessions.
- `offload=8/8` for NP6 sessions.

- `flag 0x81` means regular traffic.
- `flag 0x82` means IPsec traffic.

Example IPv4 NP6 session

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=2 expire=3597 timeout=3600 flag-
s=00000000 sockflag=00000000 sockport=0 av_idx=0 use=3

```

diagnose npu np6 session-stats <np6-id> (number of NP6 IPv4 and IPv6 sessions)

You can use the `diagnose npu np6 portlist` command to list the NP6-ids and the interfaces that each NP6 is connected to. The <np6-id> of np6_0 is 0, the <np6-id> of np6_1 is 1 and so on. The `diagnose npu np6 session-stats <np6-id>` command output incudes the following headings:

- `ins44` installed IPv4 sessions
- `ins46` installed NAT46 sessions
- `del4` deleted IPv4 and NAT46 sessions
- `ins64` installed NAT64 sessions
- `ins66` installed IPv6 sessions
- `del6` deleted IPv6 and NAT64 sessions
- `e` is the error counter for each session type

```
diagnose npu np6 session-stats 0
qid    ins44       ins46       del4        ins64       ins66       del6
       ins44_e     ins46_e     del4_e      ins64_e     ins66_e     del6_e
---------------- ---------- ---------- ---------- ---------- ----------

diagnose sys mcast-session/session6 list (IPv4 and IPv6 multicast sessions)

This command lists all IPv4 or IPv6 multicast sessions. If a multicast session can be offloaded, the output includes the `offloadable` tag. If the multicast path can be offloaded one of the paths in the command output is tagged as `offloaded`.

The only way to determine the number of offloaded multicast sessions is to use the `diagnose sys mcast-session/session6 list` command and count the number of sessions with the `offload` tag.

```
diagnose sys mcast-session list
session info: id=3 vf=0 proto=17 172.16.200.55.51108->239.1.1.1.7878
used=2 path=11 duration=1 expire=178 indev=6 pkts=2 state:2cpu offloadable

path: 2cpu policy=1, outdev=68
      out-vtag=0
```

diagnose npu np6 sse-stats <np6-id> (number of NP6 sessions and dropped sessions)

This command displays the total number of inserted, deleted and purged sessions processed by a selected NP6 processor. The number of dropped sessions of each type cam be determined by subtracting the number of successfull sessions from the total number of sessions. For example, the total number of dropped insert sessions is `insert-total - insert-success`.

```
diagnose npu np6 sse-stats 0
Counters         SSE0             SSE1             Total
---------------- ---------------- ---------------- ----------------
active           0                0                0
insert-total     25               0                0
insert-success   25               0                0
delete-total     25               0                0
delete-success   25               0                0
purge-total      0                0                0
purge-success    0                0                0

diagnose npu np6 dce <np6-id> (number of dropped NP6 packets)

This command displays the number of dropped packets for the selected NP6 processor.

- `IHP1_PKTCHK` number of dropped IP packets
- `IPSEC0_ENGINB0` number of dropped IPSec
- `TPE_SHAPER` number of dropped traffic sharper packets

```
diagnose npu np6 dce 1
IHP1_PKTCHK :0000000000001833 [5b] IPSEC0_ENGINB0 :0000000000000003 [80]
TPE_SHAPER :0000000000000552 [94]
```

diagnose hardware deviceinfo nic <interfac-name> (number of packets dropped by an interface)

This command displays a wide variety of statistics for FortiGate interfaces. The fields `Host Rx dropped` and `Host Tx dropped` display the number of received and trasmitted packets that have been dropped.

```
diagnose hardware deviceinfo nic port2
...
============ Counters ===========
Rx Pkts          :20482043

dianose npu np6 synproxy-stats (NP6 SYN-proxied sessions and unacknowledged SYNs)

This command display information about NP6 syn-proxy sessions including the total number proxied sessions. As well the `Number of attacks, no ACK from client` shows the total number of unacknowledge SYNs.

```
diagnose npu np6 synproxy-stats
DoS SYN-Proxy:
Number of proxied TCP connections : 39277346
Number of working proxied TCP connections : 182860
Number of retired TCP connections : 39094486
Number of attacks, no ACK from client : 208
```

Chapter 13 - High Availability

This FortiOS Handbook chapter contains the following sections:

Solving the High Availability problem describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

An introduction to the FGCP introduces the FGCP clustering protocol and many of its features and terminology.

FGCP configuration examples and troubleshooting describes configuring HA clusters and contains HA clustering configuration examples.

Virtual clusters describes configuring HA virtual clusters and contains virtual clustering configuration examples.

Full mesh HA describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

Operating a cluster describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

HA and failover protection describes in detail how FortiGate HA device failover, link failover, and session failover work.

HA and load balancing describes how FGCP HA active-active load balancing works and how to configure it.

HA with FortiGate-VM and third-party products describes how FortiGate units interact with third-party products.

VRRPdescribes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

FortiGate Session Life Support Protocol (FGSP) describes how to use the FGSP feature to support using external routers or load balancers to distribute or load balance sessions between two peer FortiGate units.

Configuring FRUP describes how to set up a FortiGate Redundant UTM Protocol (FRUP) cluster consisting of two FortiGate-100D units.

FortiOS 5.2 HA new features

New FortiOS 5.2 HA features are described in the following sections:

- An introduction to the FGCP on page 1270.
- DHCP and PPPoE supported for HA clusters, An introduction to the FGCP on page 1270.
- IPv6 Management Interface Gateway, Configuring the reserved management interface and SNMP remote management of individual cluster units on page 1423.
- IKEv2 Message ID synchronization and failover support, Synchronizing IPsec VPN SAs on page 1484.
- Synchronizing GTP Tunnel sessions and GTP tunnel failover support, FortiOS Carrier GTP session failover on page 1500.
- New VRRP features VRRP on page 1528 and Using a Second Destination IP (VRDST) on page 1531.

Solving the High Availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

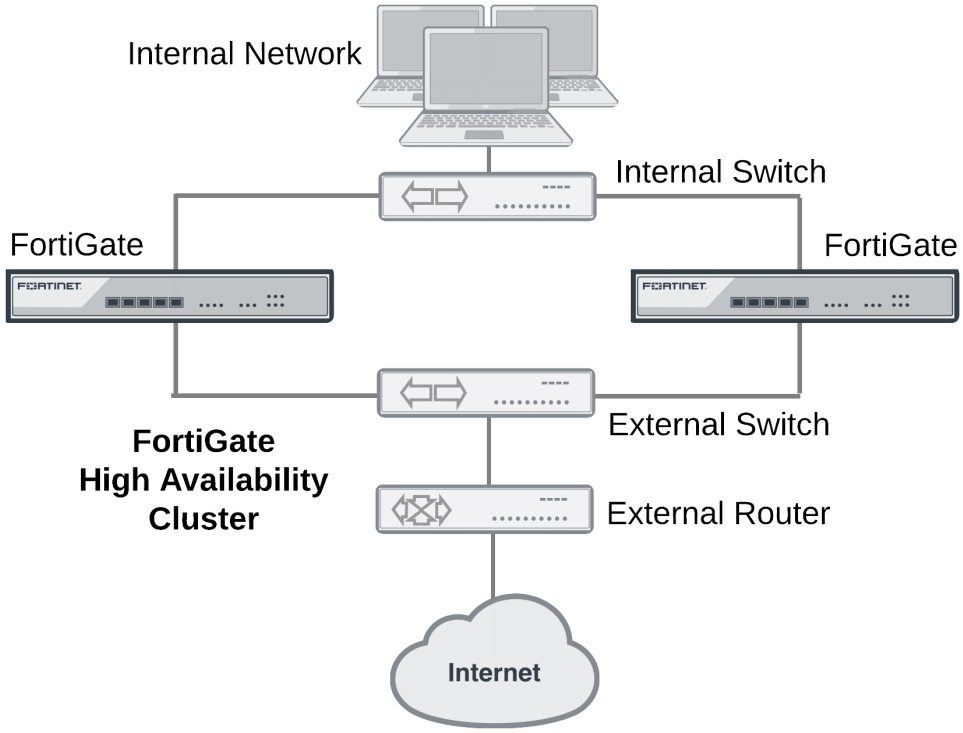
A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides four redundancy solutions: industry standard VRRP as well as three proprietary solutions: FortiGate Cluster Protocol (FGCP) high availability, FortiGate Session Life Support Protocol (FGSP) high availability, and the Fortinet Redundant UTM protocol (FRUP) high availability.

You can combine more than one high availability solution into a single configuration. A common reason for doing this could be to add VRRP to an FGCP or FGSP configuration.

A strong and flexible High availability solution is required for many mission-critical firewall and security profile applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

FortiGate Cluster Protocol (FGCP)

FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection and remote link failover protection. Also contributing to enhanced reliability is session failover protection for most IPv4 and IPv6 sessions including TCP, UDP, ICMP, IPsec VPN, and NAT sessions. Increased performance is achieved though active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

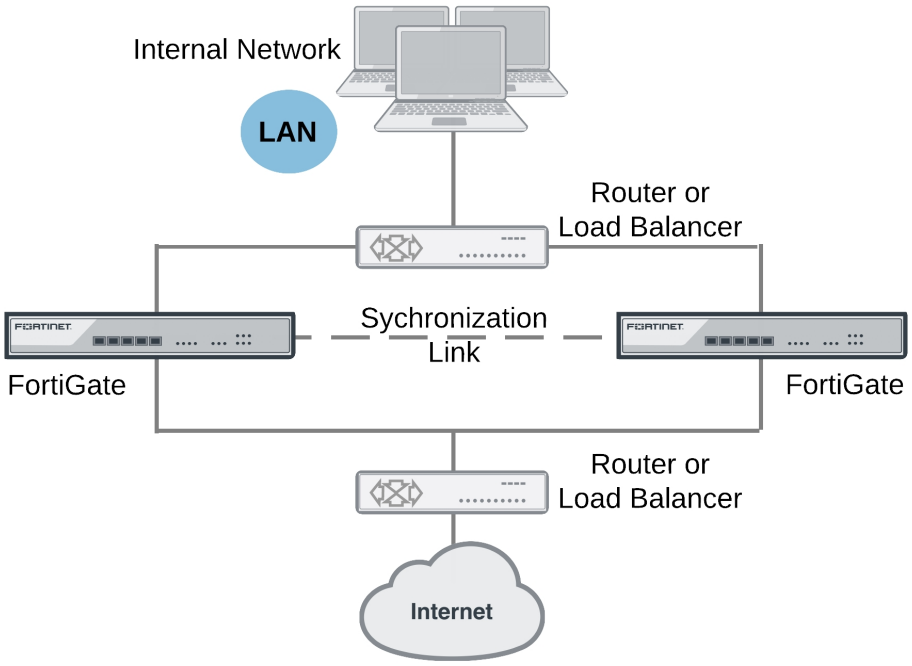


When configured onto your network an FGCP cluster appears to be a single FortiGate unit operating in NAT/Route or Transparent mode and configuration synchronization allows you to configure a cluster in the same way as a standalone FortiGate unit. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGate units can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGate units and the FGSP performs session synchronization of IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGate units synchronized.



If one of the FortiGate units fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

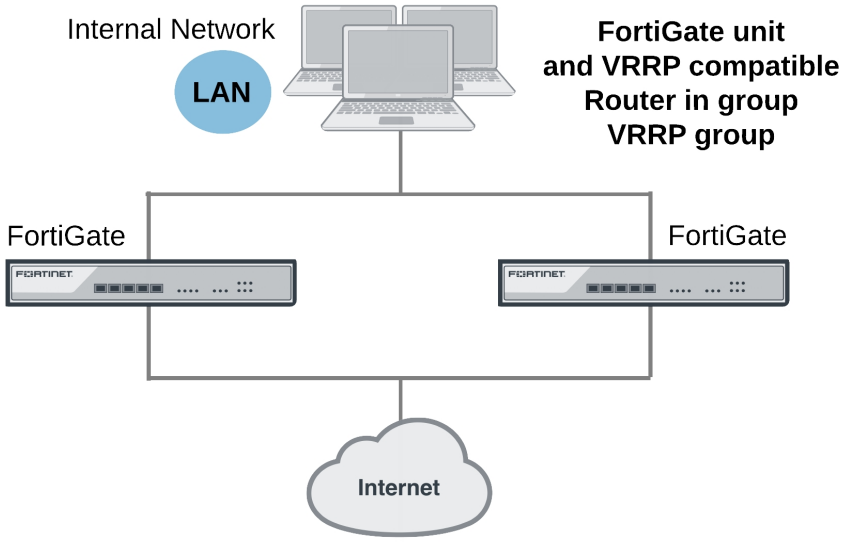
Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGate units just perform session synchronization which allows session failover to occur without packet loss.

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGate units instead of requiring duplicate configuration changes on each unit. Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate unit maintains its identity on the network. These settings must be configured separately for each FortiGate unit.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

VRRP

FortiGate units can function as master or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate unit can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGate units.



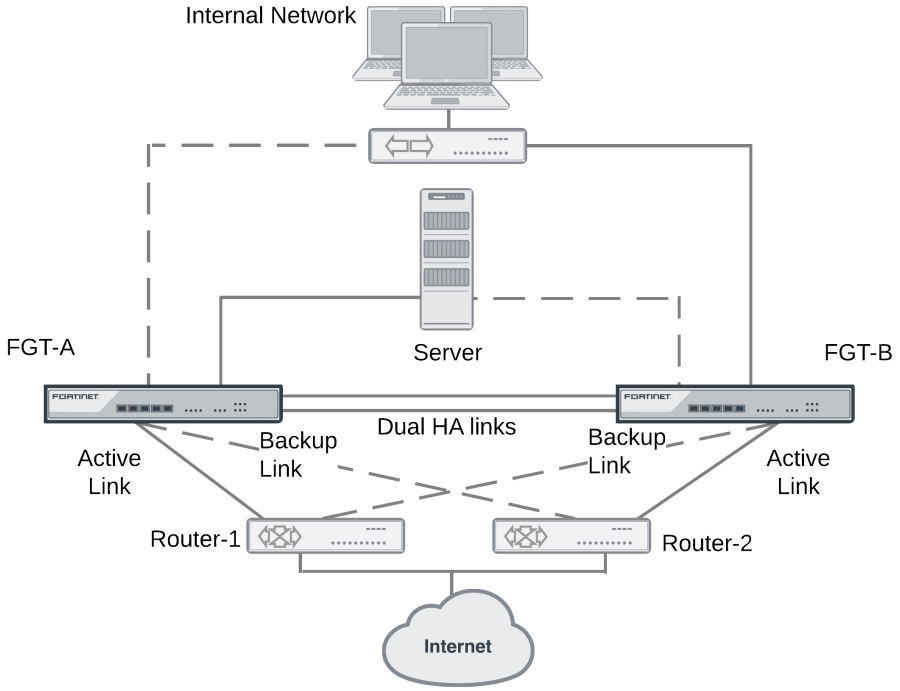
In a VRRP configuration, when a FortiGate unit operating as the master unit fails, a backup unit takes its place and continues processing network traffic. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports VRRP between two or more FortiGate units and between FortiGate units and third-party routers that support VRRP. Using VRRP you can assign VRRP routers as master or backup routers. The master router processes traffic and the backup routers monitor the master router and can begin forwarding traffic if the master fails. Similar to the FGCP you can configuration VRRP between multiple FortiGate units to provide redundancy. You can also create a VRRP group with a FortiGate units and any routers that support VRRP.

In a VRRP configuration that consists of one FortiGate unit and one router, normally the FortiGate unit would be the master and all traffic would be processed by the FortiGate unit. If the FortiGate unit fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features will be unavailable until the FortiGate unit can is back on line.

Fortinet redundant UTM protocol (FRUP)

An extension to the FGCP combines switching HA and firewall HA into a single unified design. This feature is available on the FortiGate-100D and will be expanded to other models in future releases.



A FRUP setup consists of 2 (and only 2) identical FortiGate-100D units. The setup supports dual redundant HA links between the units for sharing session and configuration data.

FRUP requires redundant external routers where:

- One FortiGate unit has a primary connection to one of the routers and a backup connection to the other.
- The other FortiGate unit has the opposite configuration.

Session-Aware Load Balancing Clustering (SLBC)

Session-Aware Load Balancing Clusters consist of one or more FortiControllers acting as load balancers and FortiGate-5000s and operating as workers all installed in one or two FortiGate-5000 series chassis.

SLBC clusters load balance TCP and UDP sessions. As a session-aware load balancer, the FortiController includes FortiASIC DP processors that maintain state information for all TCP and UDP sessions. The FortiASIC DP processors are capable of directing any TCP or UDP session to any worker installed in the same chassis. This session-awareness means that all TCP and UDP traffic being processed by a specific worker continues to be processed by the same worker. Session-awareness also means that more complex networking features such as network address translation (NAT), fragmented packets, complex UDP protocols, and complex protocols such as SIP that use pinholes, can be load balanced by the cluster.

For more informationa bout SLBC see the *FortiController Session-Aware Load Balancing Guide*.

You cannot mix FGCP and SLBC clusters in the same FortiGate-5000 chassis.

Enhanced Load Balancing Clustering (ELBC)

ELBC uses FortiSwitch-5000 series load balancers to load balance traffic to FortiGate-5000 workers installed in a FortiGate-5000 chassis. ELBC enhances scalability, reliability, and availability of mission critical IP-based services, such as firewall, antivirus, web filtering, IPS, and so on. It also provides high availability by detecting worker failures and automatically redistributing traffic to the workers that are still operating.

ELBC applies a load balancing algorithm against the source and/or destination address of packets to generate a hash key value. Each worker has hash key values assigned to it. If the workers are running, then the traffic is forwarded to the worker assigned to the hash key.The hash key value generated by the algorithm, the hash keys accepted by the worker blades, and the blade the traffic is sent to are automatically calculated by the FortiSwitch.

For more information about ELBC see the *ELBC Configuration Guide*.

You cannot mix FGCP and ELBC clusters in the same FortiGate-5000 chassis.

Content clustering

A content cluster employs FortiSwitch-5203Bs or FortiController-5902Ds to load balance content sessions to FortiGate-5000 workers. FortiSwitch-5203B content clusters consist of one or more FortiSwitch-5203Bs and multiple FortiGate-5001Bs workers. FortiController-5902D content clusters consist of one or more FortiController-5902Ds and multiple FortiGate-5001B workers.

Operating as a FortiGate unit in content cluster mode, a primary FortiSwitch-5203B or FortiController-5902D performs routing, firewalling, stateful inspection, IPsec and SSL VPN encryption/decryption, and other FortiGate functions. The FortiSwitch-5203B includes NP4 processors and the FortiController-5902Ds includes NP6 processors and an integrated switch fabrics that provides fastpath acceleration by offloading communication sessions from the FortiGate CPU.

Using content cluster weighted load balancing, the FortiSwitch-5203Bs or FortiController-5902Ds distribute sessions that require content processing to the workers over the FortiGate-5000 chassis fabric backplane. Content processing sessions include proxy and flow-based security profile functions such as virus scanning, intrusion protection, application control, IPS, web filtering, email filtering, and VoIP. Lload balancing is offloaded to the NP4 or NP6 processors resulting in improved load balancing performance. In some networks, the NP4 or NP6 processors also allow you to configure the efficiently load balance TCP and UDP sessions.

Content cluster mode is similar to active-active HA where the FortiSwitch-5203B or FortiController-5902D operates as the primary unit and load balances security profile sessions to the workers installed in the chassis using weighted load balancing. In this configuration, the HA mode is active-active, the HA load balancing schedule is weight-round-robin and load-balance-all is disabled. You can adjust the HA weighted load balancing weights to change how sessions are load balanced.

You can add a second FortiSwitch-5203B or FortiController-5902D to a content cluster as a backup. The primary FortiSwitch-5203B or FortiController-5902D can load balance sessions to the backup FortiSwitch-5203B or FortiController-5902D as well as the workers. You can control how many sessions are processed by the backup FortiSwitch-5203B or FortiController-5902D by configuring the HA load balancing weights. You can also configure the content cluster to operate the backup FortiSwitch-5203B or FortiController-5902D in standby mode. In this

mode the backup FortiSwitch-5203B or FortiController-5902D does not process any sessions but is just there to take over content clustering if the primary unit fails.

Once the content cluster has been established and all FortiControllers and workers have joined the cluster, you can configure the cluster from the FortiSwitch-5203B or FortiController-5902D GUI or CLI. All configuration changes made to the primary unit are automatically synchronized to all cluster units.

FortiSwitch-5203B or FortiController-5902D firmware upgrades are done from the primaryFortiSwitch-5203B or FortiController-5902D GUI or CLI. Worker firmware upgrades are done from theFortiSwitch-5203B or FortiController-5902D CLI where a single firmware image is uploaded once and synchronized to all of the workers.

An introduction to the FGCP

A FortiGate HA cluster consists of two to four FortiGate units configured for HA operation. Each FortiGate unit in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same AMC modules installed in the same slots, the same number of hard disks and so on) and be running in the same operating mode (NAT/Route mode or Transparent mode).

You can create an FGCP cluster of up to four FortiGate units.

In addition the cluster units must be able to communicate with each other through their heartbeat interfaces. This heartbeat communication is required for the cluster to be created and to continue operating. Without it, the cluster acts like a collection of standalone FortiGate units.

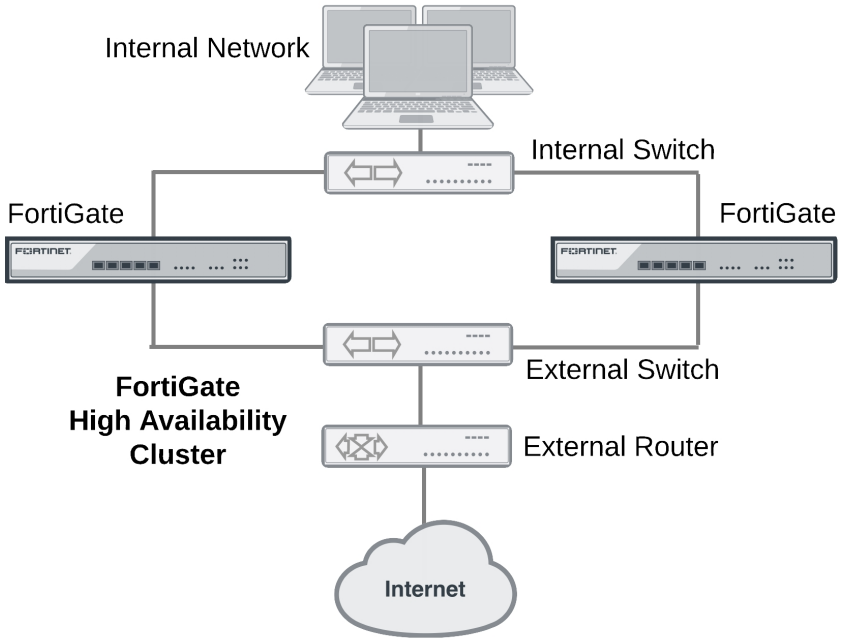
On startup, after configuring the cluster units with the same HA configuration and connecting their heartbeat interfaces, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGate units configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units over the heartbeat interface link. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat.

The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

About the FGCP

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewalling, security profile services, and VPN services.

HA cluster installed between an internal network and the Internet



Inside the cluster the individual FortiGate units are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The role that the subordinate units play depends on the mode in which the cluster operates: (Active-Passive (AP) or Active-Active (AA).

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FGCP failover means that your network does not have to rely on one FortiGate unit to continue functioning. You can install additional units and form an HA cluster.

A second HA feature, called load balancing, can be used to increase performance. A cluster of FortiGate units can increase overall network performance by sharing the load of processing network traffic and providing security services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for Virtual Domains (VDOMs). See Virtual clusters on page 1387.

FortiGate models that support redundant interfaces can be configured to support full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see Full mesh HA on page 1407.

FGCP failover protection

The FGCP provides IP/MAC takeover for failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking timers, routing table update timers, and wait timers.

An HA cluster fails over if the primary unit fails (a device failure) or experiences a link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

Session Failover

FGCP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover multicast, or SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP, UDP, and ICMP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if it is not required.

Load Balancing

Active-active HA load balances resource-intensive security profile features such as virus scanning, web filtering, intrusion protection, application control, email filtering and data leak prevention operations among all cluster units to provide better performance than a standalone FortiGate unit. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. On some FortiGate models you can also load balance UDP sessions. NP4 and NP6 offloading can accelerate HA load balancing (especially TCP and UDP load balancing). HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

Virtual Clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic. It is possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

Full Mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a single FortiGate unit) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a normal cluster configuration, single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate unit and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate/redundant interface and HA configurations.

Cluster Management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate unit by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can configure FortiGate features such as firewalling, content inspection, and VPN in the same way as for a standalone FortiGate unit. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT/Route to Transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. A new unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. An extensive range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These message can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units.

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate unit host name. Allows you to identify cluster units.
- HA override.
- HA device priority.
- Virtual cluster 1 and Virtual cluster 2 device priorities.
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration.
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface.
- The default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.
- The dynamic weighted load balancing thresholds and high and low watermarks.

Synchronizing the configuration (and settings that are not synchronized)

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units. This includes special configuration settings

that include extra information (for example, 3rd party certificates, replacement message text files and graphics and so on).

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate unit host name. Allows you to identify cluster units.
- HA override.
- HA device priority.
- Virtual cluster 1 and Virtual cluster 2 device priorities.
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration.
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface.
- The default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.
- The dynamic weighted load balancing thresholds and high and low watermarks.

In addition licenses are not synchronized since FortiGate must be licensed separately. This includes FortiCloud activationand FortiClien licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS). FortiToken licenses can be added at any time because they are synchronized to all cluster members.

Preparing the FortiGates before setting up a FGCP cluster

Before creating an FGCP cluster you should complete the following setup on each FortiGate.

DHCP and PPPoE

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Firmware version

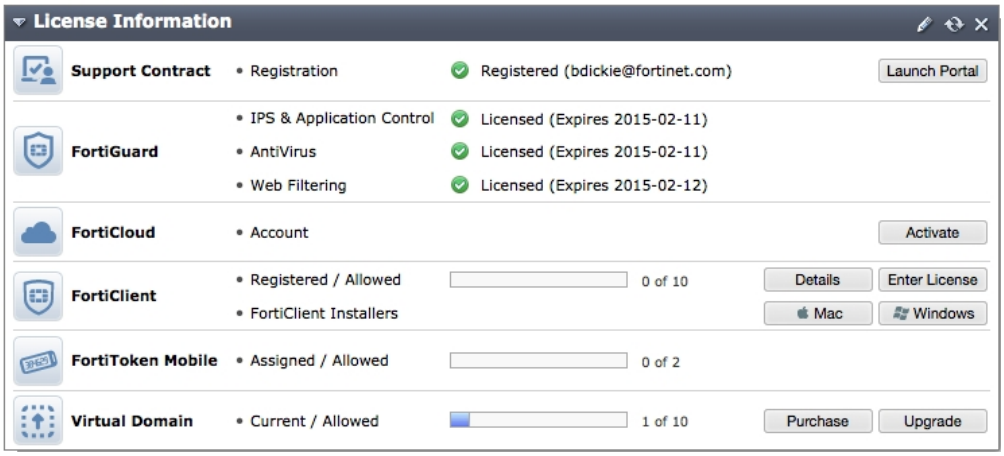
Make sure the FortiGates are running the same FortiOS firmware version.

FortiOS Carrier license

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

Licenses (Support, FortiGuard, FortiCloud, FortiClient, FortiToken Mobile, VDOMs)

Register and apply licenses to each FortiGate. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS). FortiToken licenses can be added at any time because they are synchronized to all cluster members.



Certificates

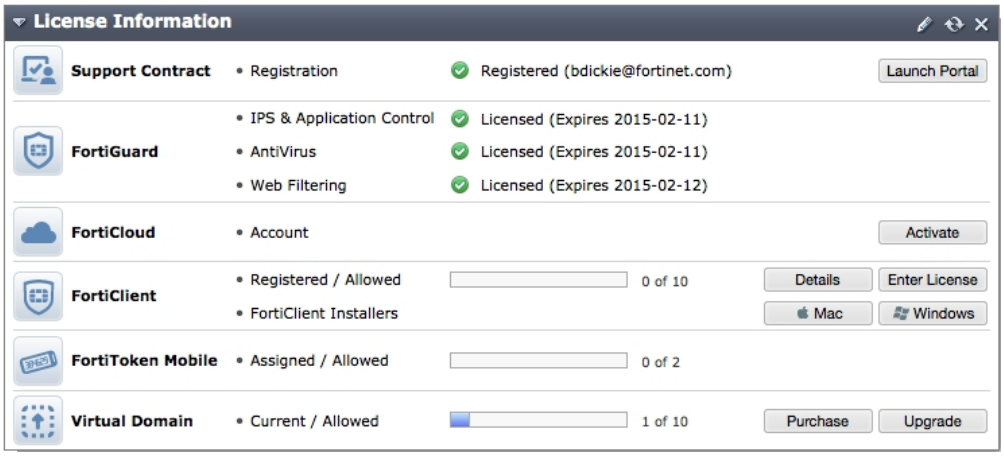
You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.

Configuring FortiGate units for FGCP HA operation

Each FortiGate unit in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate unit. The following example sets the HA mode to active-passive and the HA password to HA_pass.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP or PPPoE you should temporarily switch it to a static address and enable DHCP or PPPoE after the cluster has been established.

Make sure both FortiGates are running the same FortiOS firmware version. Register and apply licenses to both FortiGates before adding them to the cluster. This includes FortiCloud activation and FortiClient licensing, and entering a license key if you purchased more than 10 Virtual Domains (VDOMS).



You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
FortiToken licenses can be added at any time because they are synchronized to all cluster members.

To configure a FortiGate unit for HA operation - web-based manager

1. Power on the FortiGate unit to be configured.
2. Log into the web-based manager.
3. On the Dashboard **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.
   Changing the host name makes it easier to identify individual cluster units when the cluster is operating.
5. Go to **System > Config > HA** and change the following settings:

Mode	Active-Passive
Group Name	Example_cluster
Password	HA_pass The password must be the same for all FortiGate units in the cluster.

   You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all ARP table entries). You may be able to delete the ARP table of your management PC from a command prompt using a command similar to `arp -d`.
7. Power off the FortiGate unit.
8. Repeat this procedure for all of the FortiGate units in the cluster.
   Once all of the units are configured, continue by connecting the FortiGate HA cluster below.

To configure a FortiGate unit for HA operation - CLI

1. Power on the FortiGate unit to be configured.
2. Log into the CLI.
3. Enter the following command to change the FortiGate unit host name.

```
config system global
   set hostname Example1_host
end
```

   Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

4. Enter the following command to enable HA:

```
config system ha
   set mode active-passive
   set group-name Example_cluster
   set password HA_pass
end
```

   You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

   The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with

the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces. To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

5. Power off the FortiGate unit.
6. Repeat this procedure for all of the FortiGate units in the cluster.
   Once all of the units are configured, continue with connecting the FortiGate HA cluster.

Connecting a FortiGate HA cluster

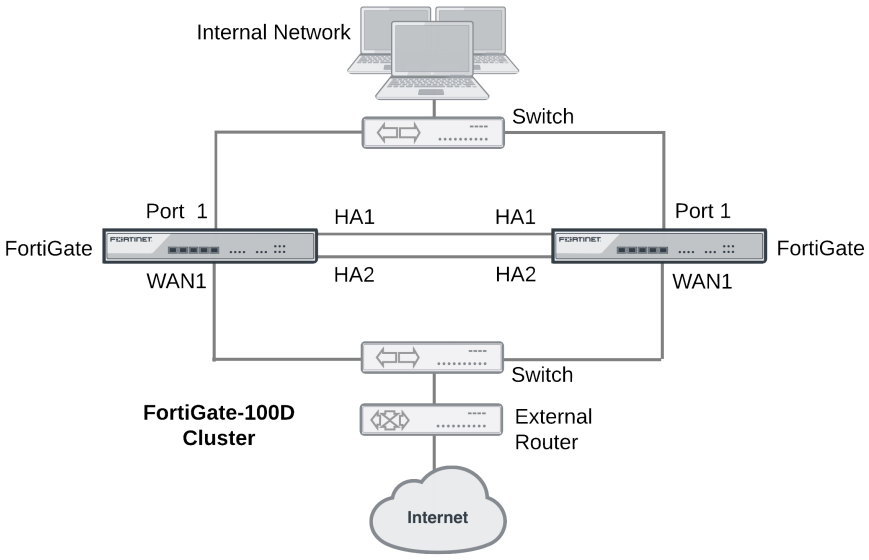
Use the following procedure to connect a cluster. Connect the cluster units to each other and to your network. You must connect all matching interfaces in the cluster to the same switch, then connect these interfaces to their networks using the same switch.

Although you can use hubs, Fortinet recommends using switches for all cluster connections for the best performance.

Connecting an HA cluster to your network temporarily interrupts communications on the network because new physical connections are being made to route traffic through the cluster. Also, starting the cluster interrupts network traffic until the individual cluster units are functioning and the cluster completes negotiation. Cluster negotiation is automatic and normally takes just a few seconds. During system startup and negotiation all network traffic is dropped.

This section describes how to connect the cluster shownbelow, which consists of two FortiGate-100D units to be connected between the Internet and a head office internal network. The wan1 interfaces of the FortiGate unit connect the cluster to the Internet and the internal interfaces connect the cluster to the internal network. The ha1 and ha2 interfaces are used for redundant HA heartbeat links.

Example cluster connections



To connect a FortiGate HA cluster

1. Connect the WAN1 interfaces of each cluster unit to a switch connected to the Internet.
2. Connect the Port1 interfaces of each cluster unit to a switch connected to the internal network.
3. Connect the HA1 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
4. Connect the HA2 interfaces of the cluster units together. You can use a crossover Ethernet cable or a regular Ethernet cable. (You can also connect the interfaces using Ethernet cables and a switch.)
5. Power on both of the FortiGate units.

   As the cluster units start, they negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally just takes a few seconds.

   At least one heartbeat interface should be connected together for the cluster to operate.

   Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

   You could use one switch to connect all four heartbeat interfaces. However, this is not recommended because if the switch fails both heartbeat interfaces will become disconnected.
6. You can now configure the cluster as if it is a single FortiGate unit.

Active-passive and active-active HA

The first decision to make when configuring FortiGate HA is whether to choose active-passive or active-active HA mode. To configure the HA mode, go to **System > Config > HA** and set Mode to **Active-Passive** or **Active-Active**.

From the CLI enter the following command to set the HA mode to active-passive:

```
config system ha
   set mode a-p
end
```

To form a cluster, all cluster units must be set to the same mode. You can also change the mode after the cluster is up and running. Changing the mode of a functioning cluster causes a slight delay while the cluster renegotiates to operate in the new mode and possibly select a new primary unit.

Active-passive HA (failover protection)

An active-passive (A-P) HA cluster provides hot standby failover protection. An active-passive cluster consists of a primary unit that processes communication sessions, and one or more subordinate units. The subordinate units are connected to the network and to the primary unit but do not process communication sessions. Instead, the subordinate units run in a standby state. In this standby state, the configuration of the subordinate units is synchronized with the configuration of the primary unit and the subordinate units monitor the status of the primary unit.

Active-passive HA provides transparent device failover among cluster units. If a cluster unit fails, another immediately take its place.

Active-passive HA also provides transparent link failover among cluster units. If a cluster unit interface fails or is disconnected, this cluster unit updates the link state database and the cluster negotiates and may select a new primary unit.

If session failover (also called session pickup) is enabled, active-passive HA provides session failover for some communication sessions.

The following example shows how to configure a FortiGate unit for active-passive HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
   set mode a-p
   set group-name myname
   set password HApass
end
```

Active-active HA (load balancing and failover protection)

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Normally, sessions accepted by policies that don't include security proflies are not load balanced and are processed by the primary unit. You can configure active-active HA to load balance additional sessions.

An active-active HA cluster consists of a primary unit that receives all communication sessions and load balances them among the primary unit and all of the subordinate units. In an active-active cluster the subordinate units are also considered active since they also process content processing sessions. In all other ways active-active HA operates the same as active-passive HA.

The following example shows how to configure a FortiGate unit for active-active HA operation. You would enter the exact same commands on every FortiGate unit in the cluster.

```
config system ha
   set mode a-a
   set group-name myname
   set password HApass
end
```

Identifying the cluster and cluster units

You can use the cluster group name, group id, and password to identify a cluster and distinguish one cluster from another. If you have more than one cluster on the same network, each cluster must have a different group name, group id, and password.

Group name

Use the group name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units. The group name appears on the FortiGate dashboard of a functioning cluster as the **Cluster Name**.

To add or change the group name from the web-based manager go to **Config > System > HA** and change the **Group Name**.

Enter the following CLI command to change the group name to Cluster_name:

```
config system ha
   set group-name Cluster_name
end
```

Password

Use the password to identify the cluster. You should always change the password when configuring a cluster. The password must be the same for all FortiGate units before they can form a cluster. When the cluster is operating you can change the password, if required. Two clusters on the same network cannot have the same password.

To change the password from the web-based manager go to **Config > System > HA** and change the **Password**.

Enter the following CLI command to change the password to ha_pwd:

```
config system ha
   set password ha_pwd
end
```

Group ID

Similar to the group name, the group ID is also identifies the cluster. In most cases you do not have to change the group ID. However, you should change the group ID if you have more than one cluster on the same network. All members of the HA cluster must have the same group ID. The group ID is a number from 0 to 255.

Changing the group ID changes the cluster virtual MAC address. If two clusters on the same network have the same group ID you may encounter MAC address conflicts.

Enter the following CLI command to change the group ID to 10:

```
config system ha
   set group-id 10
end
```

Device failover, link failover, and session failover

The FGCP provides transparent device and link failover. You can also enable session pickup to provide session failover. A failover can be caused by a hardware failure, a software failure, or something as simple as a network cable being disconnected causing a link failover. When a failover occurs, the cluster detects and recognizes the failure and takes steps to respond so that the network can continue to operate without interruption. The internal operation of the cluster changes, but network components outside of the cluster notice little or no change.

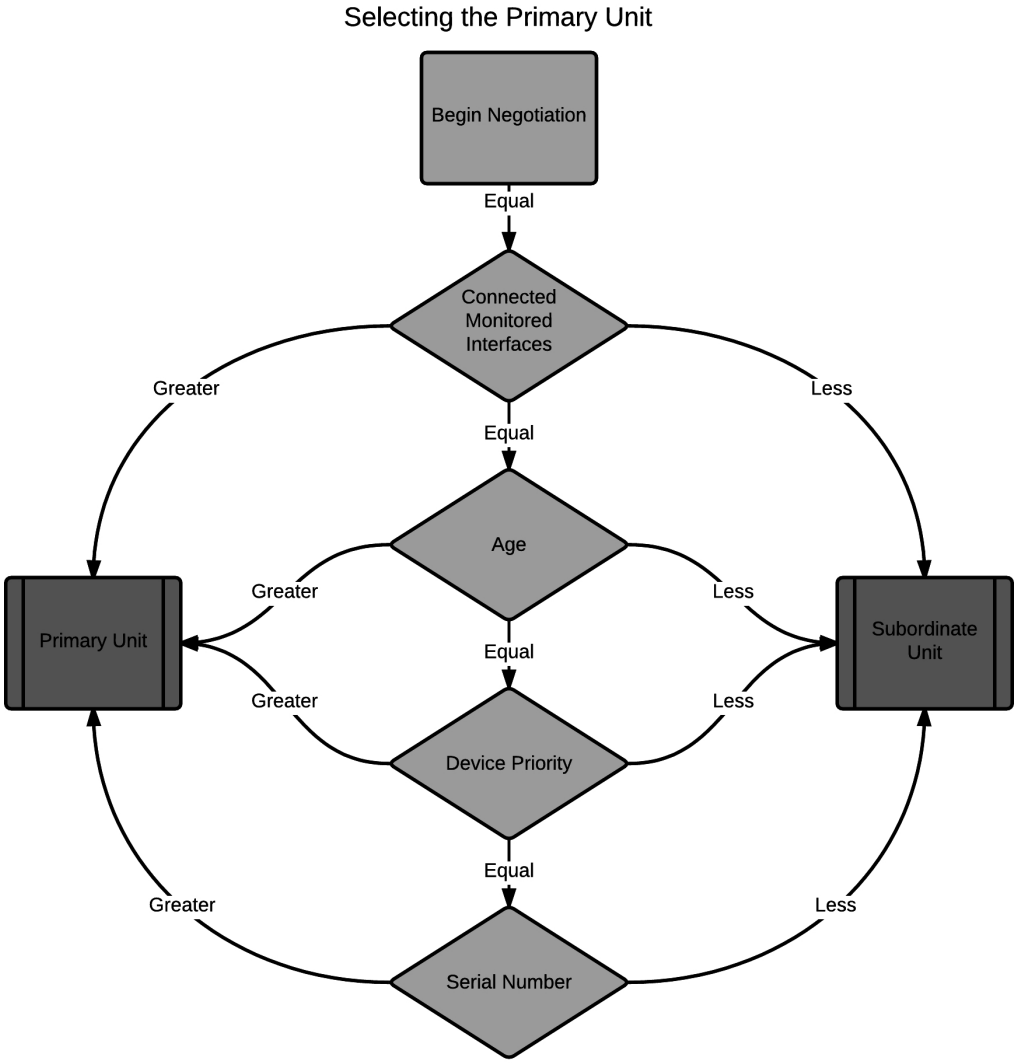
If a failover occurs, the cluster also records log messages about the event and can be configured to send log messages to a syslog server and to a FortiAnalyzer unit. The cluster can also send SNMP traps and alert email messages. These alerts can notify network administrators of the failover and may contain information that the network administrators can use to find and fix the problem that caused the failure.

For a complete description of device failover, link failover, and session failover, how clusters support these types of failover, and how FortiGate HA clusters compensate for a failure to maintain network traffic flow see HA and failover protection on page 1455.

Primary unit selection

Once FortiGate units recognize that they can form a cluster, the cluster units negotiate to select a primary unit. Primary unit selection occurs automatically based on the criteria shown below. After the cluster selects the primary unit, all of the remaining cluster units become subordinate units.

Negotiation and primary unit selection also takes place if a primary unit fails (device failover) or if a monitored interface fails or is disconnected (link failover). During a device or link failover, the cluster renegotiates to select a new primary unit also using the criteria shown below.



For many basic HA configurations primary unit selection simply selects the cluster unit with the highest serial number to become the primary unit. A basic HA configuration involves setting the HA mode to active-passive or active-active and configuring the cluster group name and password. Using this configuration, the cluster unit with the highest serial number becomes the primary unit because primary unit selection disregards connected monitored interfaces (because interface monitoring is not configured), the age of the cluster units would usually always be the same, and all units would have the same device priority.

Using the serial number is a convenient way to differentiate cluster units; so basing primary unit selection on the serial number is predictable and easy to understand and interpret. Also the cluster unit with the highest serial number would usually be the newest FortiGate unit with the most recent hardware version. In many cases you may not need active control over primary unit selection, so basic primary unit selection based on serial number is sufficient.

In some situations you may want have control over which cluster unit becomes the primary unit. You can control primary unit selection by setting the device priority of one cluster unit to be higher than the device priority of all other cluster units. If you change one or more device priorities, during negotiation, the cluster unit with the highest device priority becomes the primary unit. As shown above, the FGCP selects the primary unit based on device priority before serial number. For more information about how to use device priorities, see Primary unit selection and device priority on page 1285.

The only other way that you can influence primary unit selection is by configuring interface monitoring (also called port monitoring). Using interface monitoring you can make sure that cluster units with failed or disconnected monitored interfaces cannot become the primary unit. See Primary unit selection and monitored interfaces on page 1282.

Finally, the age of a cluster unit is determined by a number of operating factors. Normally the age of all cluster units is the same so normally age has no effect on primary unit selection. Age does affect primary unit selection after a monitored interface failure. For more information about age, see Primary unit selection and age on page 1282.

Primary unit selection and monitored interfaces

If you have configured interface monitoring the cluster unit with the highest number of monitored interfaces that are connected to networks becomes the primary unit. Put another way, the cluster unit with the highest number of failed or disconnected monitored interfaces cannot become the primary unit.

Normally, when a cluster starts up, all monitored interfaces of all cluster units are connected and functioning normally. So monitored interfaces do not usually affect primary unit selection when the cluster first starts.

A cluster always renegotiates when a monitored interface fails or is disconnected (called link failover). A cluster also always renegotiates when a failed or disconnected monitored interface is restored.

If a primary unit monitored interface fails or is disconnected, the cluster renegotiates and if this is the only failed or disconnected monitored interface the cluster selects a new primary unit.

If a subordinate unit monitored interface fails or is disconnected, the cluster also renegotiates but will not necessarily select a new primary unit. However, the subordinate unit with the failed or disconnected monitored interface cannot become the primary unit.

Multiple monitored interfaces can fail or become disconnected on more than one cluster unit. Each time a monitored interface is disconnected or fails, the cluster negotiates to select the cluster unit with the most connected and operating monitored interfaces to become the primary unit. In fact, the intent of the link failover feature is just this, to make sure that the primary unit is always the cluster unit with the most connected and operating monitored interfaces.

Primary unit selection and age

The cluster unit with the highest age value becomes the primary unit. The age of a cluster unit is the amount of time since a monitored interface failed or is disconnected. Age is also reset when a cluster unit starts (boots up). So, when all cluster units start up at about the same time, they all have the same age. Age does not affect primary unit selection when all cluster units start up at the same time. Age also takes precedence over priority for primary unit selection.

If a link failure of a monitored interface occurs, the age value for the cluster unit that experiences the link failure is reset. So, the cluster unit that experienced the link failure also has a lower age value than the other cluster units. This reduced age does not effect primary unit selection because the number of link failures takes precedence over the age.

If the failed monitored interface is restored the cluster unit that had the failed monitored interface cannot become the primary unit because its age is still lower than the age of the other cluster units.

In most cases, the way that age is handled by the cluster reduces the number of times the cluster selects a new primary unit, which results in a more stable cluster since selecting a new primary unit has the potential to disrupt traffic.

Cluster age difference margin (grace period)

In any cluster, some of the cluster units may take longer to start up than others. This startup time difference can happen as a result of a number of issues and does not affect the normal operation of the cluster. To make sure that cluster units that start slower can still become primary units, by default the FGCP ignores age differences of up to 5 minutes (300 seconds).

In most cases, during normal operation this age difference margin or grace period helps clusters function as expected. However, the age difference margin can result in some unexpected behavior in some cases:

- During a cluster firmware upgrade with `uninterruptible-upgrade` enabled (the default configuration) the cluster should not select a new primary unit after the firmware of all cluster units has been updated. But since the age difference of the cluster units is most likely less than 300 seconds, age is not used to affect primary unit selection and the cluster may select a new primary unit.
- During failover testing where cluster units are failed over repeatedly the age difference between the cluster units will most likely be less than 5 minutes. During normal operation, if a failover occurs, when the failed unit rejoins the cluster its age will be very different from the age of the still operating cluster units so the cluster will not select a new primary unit. However, if a unit fails and is restored in a very short time the age difference may be less than 5 minutes. As a result the cluster may select a new primary unit during some failover testing scenarios.

Changing the cluster age difference margin

You can change the cluster age difference margin using the following command:

```
config system ha
   set ha-uptime-diff-margin 60
end
```

This command sets the cluster age difference margin to 60 seconds (1 minute). The age difference margin range 1 to 65535 seconds. The default is 300 seconds.

You may want to reduce the margin if during failover testing you don't want to wait the default age difference margin of 5 minutes. You may also want to reduce the margin to allow uninterruptible upgrades to work. See Upgrading cluster firmware on page 1439.

You may want to increase the age margin if cluster unit startup time differences are larger than 5 minutes.

Displaying cluster unit age differences

You can use the CLI command `diagnose sys ha dump-by all-vcluster` to display the age difference of the units in a cluster. This command also displays information about a number of HA-related parameters for each cluster unit. You can enter the command from the primary unit CLI or you can enter the command from a subordinate unit after using `execute ha manage` to log into a subordinate unit CLI. The information displayed by the command is relative to the unit that you enter the command from.

For example, a cluster of two FortiGate-5001C units with no changes to the default HA configuration except to enable port monitoring for port1. Entering the `diagnose sys ha dump-by all-vcluster` command from the primary unit CLI displays information similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=work, digest=4.e8.62.17.7b.1d...
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,0,claimed=0,override=0,
   flag=0x01,time=0,mon=0
   mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800051,prio=128,0,claimed=0,override=0,
   flag=0x00,time=189,mon=0
```

The command displays one `ventry` line for each cluster unit. The first `ventry` in the example contains information for the cluster unit that you are logged into (usually the primary unit). The other `ventry` lines contain information for the other units in the cluster (in the example there is only one other cluster unit). The command also includes a `mondev` entry that displays the interface monitoring configuration.

The `time` field is always `0` for the unit that you are logged into. The `time` field for the other cluster unit is the age difference between the unit that you are logged into and the other cluster unit. The age difference is in the form seconds/10.

In the example, the age of the subordinate unit is 18.9 seconds more than the age of the primary unit. The age difference is less than 5 minutes (less than 300 seconds) so age has no affect on primary unit selection. The cluster selected the unit with the highest serial number to be the primary unit.

If you use `execute ha manage 1` to log into the subordinate unit CLI and enter `diagnose sys ha dump 1` you get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=standby, digest=4.e8.62.17.7b.1d...
ventry idx=1,id=1,FG-5KC3E13800051,prio=128,0,claimed=0,override=0,
   flag=0x01,time=0,mon=0
   mondev=port1,50
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,0,claimed=1,override=0,
   flag=0x00,time=-189,mon=0
```

The `time` for the primary unit is `-189`, indicating that age of the subordinate unit age is 18.9 seconds higher than the primary unit age.

If port1 (the monitored interface) of the primary unit is disconnected, the cluster renegotiates and the former subordinate unit becomes the primary unit. When you log into the new primary unit CLI and enter `diagnose sys ha dump-by all-vcluster` you could get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=work, digest=3.f8.d1.63.4d.d2...
ventry idx=0,id=1,FG-5KC3E13800046,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0
   mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800084,prio=128,-50,claimed=0,
   override=0,flag=0,time=1362,mon=0
```

The command results show that the age of the new primary unit is 136.2 seconds higher than the age of the new subordinate unit.

If port1 of the former primary unit is reconnected the cluster will once again make this the primary unit because the age difference will still be less than 300 seconds. When you log into the primary unit CLI and enter `diagnose sys ha dump-by all-vcluster` you get results similar to the following:

```
diagnose sys ha dump-by all-vcluster
      HA information.
vcluster id=1, nventry=2, state=work, digest=4.a5.60.11.cf.d4...
ventry idx=0,id=1,FG-5KC3E13800084,prio=128,0,claimed=0,
   override=0,flag=1,time=0,mon=0
   mondev=port1,50
ventry idx=1,id=1,FG-5KC3E13800046,prio=128,0,claimed=0,
   override=0,flag=0,time=-1362,mon=0
```

Resetting the age of all cluster units

In some cases, age differences among cluster units can result in the wrong cluster unit or the wrong virtual cluster becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units when it rejoins the cluster. Since age takes precedence over priority, the priority of this cluster unit will not be a factor in primary unit selection.

This problem also affects virtual cluster VDOM partitioning in a similar way. After a reboot of one of the units in a virtual cluster configuration, traffic for all VDOMs could continue to be processed by the cluster unit that did not reboot. This can happen because the age of both virtual clusters on the unit that did not reboot is greater that the age of both virtual clusters on the unit that rebooted.

One way to resolve this issue is to reboot all of the cluster units at the same time so that the age of all of the cluster units is reset. However, rebooting cluster units may interrupt or at least slow down traffic. If you would rather not reboot all of the cluster units you can instead use the following command to reset the age of individual cluster units.

```
diagnose sys ha reset-uptime
```

This command resets the age of a unit back to zero so that if no other unit in the cluster was reset at the same time, it will now have the lowest age. You would use this command to reset the age of the cluster unit that is currently the primary unit. Since it will have the lowest age, the other unit in the cluster will have the highest age and can then become the primary unit.

The `diagnose sys ha reset-uptime` command should only be used as a temporary solution. The command resets the HA age internally and does not affect the up time displayed for cluster units using the `diagnose sys ha dump-by all-vcluster` command or the up time displayed on the Dashboard or cluster members list. To make sure the actual up time for cluster units is the same as the HA age you should reboot the cluster units during a maintenance window.

Primary unit selection and device priority

A cluster unit with the highest device priority becomes the primary unit when the cluster starts up or renegotiates. By default, the device priority for all cluster units is 128. You can change the device priority to control which FortiGate unit becomes the primary unit during cluster negotiation. All other factors that influence primary unit selection either cannot be configured (age and serial number) or are synchronized among all cluster units (interface monitoring). You can set a different device priority for each cluster unit. During negotiation, if all monitored interfaces are connected, and all cluster units enter the cluster at the same time (or have the same age), the cluster with the highest device priority becomes the primary unit.

A higher device priority does not affect primary unit selection for a cluster unit with the most failed monitored interfaces or with an age that is higher than all other cluster units because failed monitored interfaces and age are used to select a primary unit before device priority.

Increasing the device priority of a cluster unit does not always guarantee that this cluster unit will become the primary unit. During cluster operation, an event that may affect primary unit selection may not always result in the cluster renegotiating. For example, when a unit joins a functioning cluster, the cluster will not renegotiate. So if a unit with a higher device priority joins a cluster the new unit becomes a subordinate unit until the cluster renegotiates.

Enabling the `override` HA CLI keyword makes changes in device priority more effective by causing the cluster to negotiate more often to make sure that the primary unit is always the unit with the highest device priority. For more information about `override`, see Primary unit selection on page 1280.

Controlling primary unit selection by changing the device priority

You set a different device priority for each cluster unit to control the order in which cluster units become the primary unit when the primary unit fails.

To change the device priority from the web-based manager go to **Config > System > HA** and change the **Device Priority**.

Enter the following CLI command to change the device priority to 200:

```
config system ha
   set priority 200
end
```

The device priority is not synchronized among cluster units. In a functioning cluster you can change the device priority of any unit in the cluster. Whenever you change the device priority of a cluster unit, when the cluster negotiates, the unit with the highest device priority becomes the primary unit.

The following example shows how to change the device priority of a subordinate unit to 255 so that this subordinate unit becomes the primary unit. You can change the device priority of a subordinate unit by going to **Config > System > HA** and selecting the Edit icon for the subordinate unit. Or from the CLI you can use the `execute ha manage 0` command to connect to the highest priority subordinate unit. After you enter the following commands the cluster renegotiates and selects a new primary unit.

```
execute ha manage 1
   config system ha
      set priority 255
   end
```

If you have three units in a cluster you can set the device priorities as shown below. When the cluster starts up, cluster unit A becomes the primary unit because it has the highest device priority. If unit A fails, unit B becomes the primary unit because unit B has a higher device priority than unit C.

Example device priorities for a cluster of three FortiGate units

Cluster unit	Device priority
A	200
B	100
C	50

When configuring HA you do not have to change the device priority of any of the cluster units. If all cluster units have the same device priority, when the cluster first starts up the FGCP negotiates to select the cluster unit with the highest serial number to be the primary unit. Clusters also function normally if all units have the same device priority.

You can change the device priority if you want to control the roles that individual units play in the cluster. For example, if you want the same unit to always become the primary unit, set this unit device priority higher than the device priority of other cluster units. Also, if you want a cluster unit to always become a subordinate unit, set this cluster unit device priority lower than the device priority of other cluster units.

If you have a cluster of three units you can set a different priority for each unit to control which unit becomes the primary unit when all three cluster units and functioning and which will be the primary unit when two cluster units are functioning.

The device priority range is 0 to 255. The default device priority is 128.

If you are configuring a virtual cluster, if you have added virtual domains to both virtual clusters, you can set the device priority that the cluster unit has in virtual cluster 1 and virtual cluster 2. If a FortiGate unit has different device priorities in virtual cluster 1 and virtual cluster 2, the FortiGate unit may be the primary unit in one virtual cluster and the subordinate unit in the other.

Primary unit selection and the FortiGate unit serial number

The cluster unit with the highest serial number is more likely to become the primary unit. When first configuring FortiGate units to be added to a cluster, if you do not change the device priority of any cluster unit, then the cluster unit with the highest serial number always becomes the primary unit.

Age does take precedence over serial number, so if a cluster unit takes longer to join a cluster for some reason (for example if one cluster unit is powered on after the others), that cluster unit will not become the primary unit because the other units have been in the cluster longer.

Device priority and failed monitored interfaces also take precedence over serial number. A higher device priority means a higher priority. So if you set the device priority of one unit higher or if a monitored interface fails, the cluster will not use the FortiGate serial number to select the primary unit.

Points to remember about primary unit selection

Some points to remember about primary unit selection:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored interfaces > Age > Device Priority > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered if a cluster unit fails or if a monitored interface fails.

- If the HA age difference is more than 5 minutes (300 seconds), the cluster unit that is operating longer becomes the primary unit.
- If HA age difference is less than 5 minutes (300 seconds), the device priority and FortiGate serial number selects the cluster unit to become the primary unit.
- Every time a monitored interface fails the HA age of the cluster unit is reset to 0.
- Every time a cluster unit restarts the HA age of the cluster unit is reset to 0.

Temporarily setting a cluster unit to be the primary unit

You can use the following diagnose command to set a cluster unit to be the primary unit.

```
diagnose sys ha set-as-master enable
```

This command is intended for demonstration purposes and not for production use. This command may not be visible for all FortiOS versions.

When you enter this command, the cluster immediately re-negotiates and the cluster unit on which you entered this command becomes the primary unit. This change is temporary and will be reverted if the cluster unit restarts.

You can also use the following command from the same cluster unit to turn this option off, causing the cluster to renegotiate and select a new primary unit.

```
diagnose sys ha set-as-master disable
```

You can also configure when to disabling the set-as-master setting. For example, to disable the set as master setting on January 25, 2015 you can enter a date after the disable keyword:

```
diagnose sys ha set-as-master disable 2015 01 25
```

HA override

The HA `override` CLI keyword is disabled by default. When `override` is disabled a cluster may not always renegotiate when an event occurs that affects primary unit selection. For example, when `override` is disabled a cluster will not renegotiate when you change a cluster unit device priority or when you add a new cluster unit to a cluster. This is true even if the unit added to the cluster has a higher device priority than any other unit in the cluster. Also, when `override` is disabled a cluster does not negotiate if the new unit added to the cluster has a failed or disconnected monitored interface.

For a virtual cluster configuration, `override` is enabled by default for both virtual clusters when you enable virtual cluster 2. For more information, see Virtual clustering and HA override on page 1388.

In most cases you should keep `override` disabled to reduce how often the cluster negotiates. Frequent negotiations may cause frequent traffic interruptions.

However, if you want to make sure that the same cluster unit always operates as the primary unit and if you are less concerned about frequent cluster negotiation you can set its device priority higher than other cluster units and enable `override`.

To enable `override`, connect to each cluster unit CLI (using the `execute ha manage` command) and use the `config system ha` CLI command to enable `override`.

For `override` to be effective, you must also set the device priority highest on the cluster unit that you want to always be the primary unit. To increase the device priority, from the CLI use the `config system ha` command and increase the value of the `priority` keyword to a number higher than the default priority of 128.

You can also increase the device priority from the web-based manager by going to **System > Config > HA**. To increase the device priority of the primary unit select edit for the primary or subordinate unit and set the **Device Priority** to a number higher than 128.

The `override` setting and device priority value are not synchronized to all cluster units. You must enable override and adjust device priority manually and separately for each cluster unit.

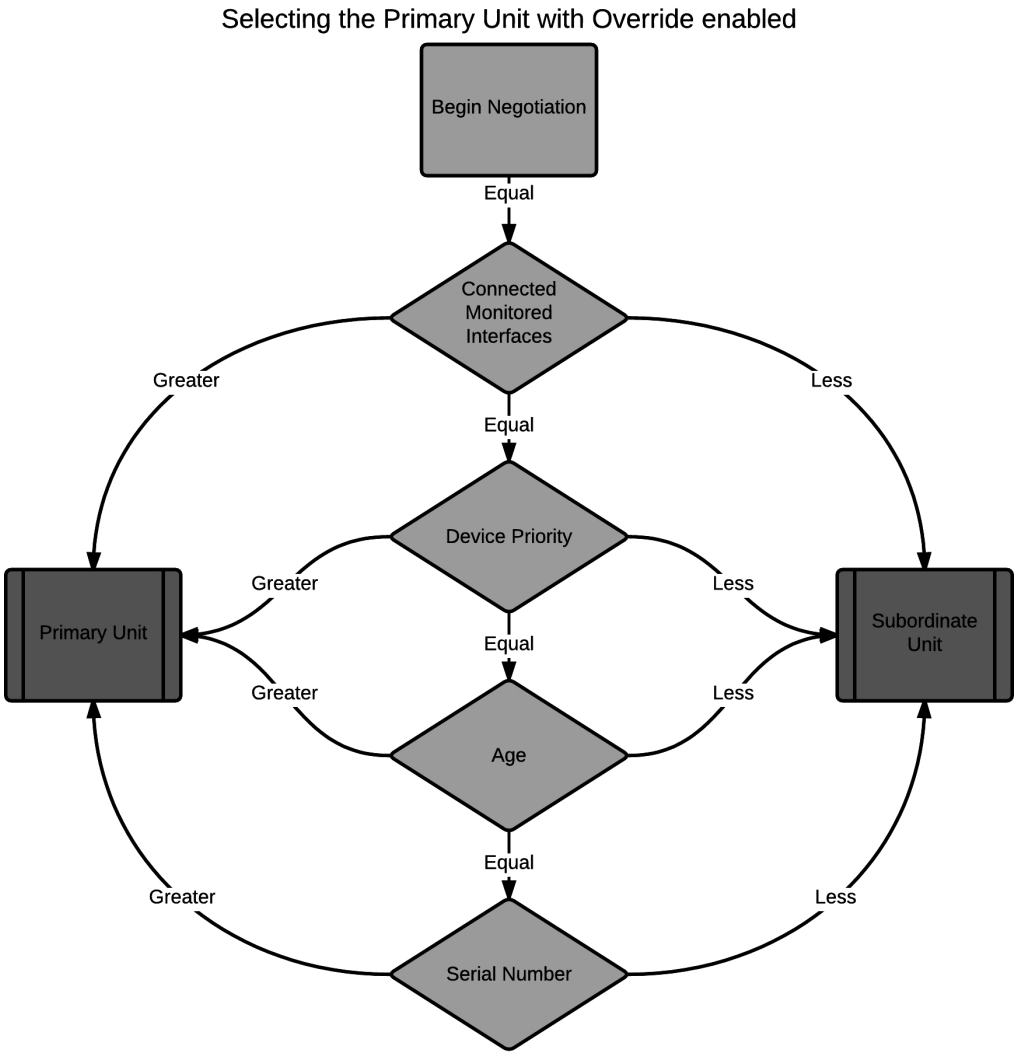
With `override` enabled, the primary unit with the highest device priority will always become the primary unit. Whenever an event occurs that may affect primary unit selection, the cluster negotiates. For example, when `override` is enabled a cluster renegotiates when you change the device priority of any cluster unit or when you add a new unit to a cluster.

Override and primary unit selection

Enabling `override` changes the order of primary unit selection. As shown below, if `override` is enabled, primary unit selection considers device priority before age and serial number. This means that if you set the device priority higher on one cluster unit, with `override` enabled this cluster unit becomes the primary unit even if its age and serial number are lower than other cluster units.

Similar to when `override` is disabled, when `override` is enabled primary unit selection checks for connected monitored interfaces first. So if interface monitoring is enabled, the cluster unit with the most disconnected monitored interfaces cannot become the primary unit, even of the unit has the highest device priority.

If all monitored interfaces are connected (or interface monitoring is not enabled) and the device priority of all cluster units is the same then age and serial number affect primary unit selection.



Controlling primary unit selection using device priority and override

To configure one cluster unit to always become the primary unit you should set its device priority to be higher than the device priorities of the other cluster units and you should enable `override` on all cluster units.

Using this configuration, when the cluster is operating normally the primary unit is always the unit with the highest device priority. If the primary unit fails the cluster renegotiates to select another cluster unit to be the primary unit. If the failed primary unit recovers, starts up again and rejoins the cluster, because `override` is enabled, the cluster renegotiates. Because the restarted primary unit has the highest device priority it once again becomes the primary unit.

In the same situation with `override` disabled, because the age of the failed primary unit is lower than the age of the other cluster units, when the failed primary unit rejoins the cluster it does not become the primary unit. Instead, even though the failed primary unit may have the highest device priority it becomes a subordinate unit because its age is lower than the age of all the other cluster units.

Points to remember about primary unit selection when override is enabled

Some points to remember about primary unit selection when `override` is enabled:

- The FGCP compares primary unit selection criteria in the following order: Failed Monitored Interfaces > Device Priority > Age > Serial number. The selection process stops at the first criteria that selects one cluster unit.
- Negotiation and primary unit selection is triggered whenever an event occurs which may affect primary unit selection. For example negotiation occurs, when you change the device priority, when you add a new unit to a cluster, if a cluster unit fails, or if a monitored interface fails.
- Device priority is considered before age. Otherwise age is handled the same when `override` is enabled.

Configuration changes can be lost if override is enabled

In some cases, when override is enabled and you make configuration changes to an HA cluster these changes can be lost. For example, consider the following sequence:

1. A cluster of two FortiGate units is operating with `override` enabled.
   - FGT-A: Primary unit with device priority 200 and with `override` enabled
   - FGT-B: Subordinate unit with device priority 100 and with `override` disabled
   - If both units are operating, FGT-A always becomes the primary unit because FGT-A has the highest device priority.
2. FGT-A fails and FGT-B becomes the new primary unit.
3. The administrator makes configuration changes to the cluster.
   The configuration changes are made to FGT-B because FGT-B is operating as the primary unit. These configuration changes are not synchronized to FGT-A because FGT-A is not operating.
4. FGT-A is restored and starts up again.
5. The cluster renegotiates and FGT-A becomes the new primary unit.
6. The cluster recognizes that the configurations of FGT-A and FGT-B are not the same.
7. The configuration of FGT-A is synchronized to FGT-B.
   The configuration is always synchronized from the primary unit to the subordinate units.
8. The cluster is now operating with the same configuration as FGT-A. The configuration changes made to FGT-B have been lost.

The solution

When `override` is enabled, you can prevent configuration changes from being lost by doing the following:

- Verify that all cluster units are operating before making configuration changes (from the web-based manager go to **System > Config > HA** to view the cluster members list or from the FortiOS CLI enter `get system ha status`).
- Make sure the device priority of the primary unit is set higher than the device priorities of all other cluster units before making configuration changes.
- Disable `override` either permanently or until all configuration changes have been made and synchronized to all cluster units.

Override and disconnecting a unit from a cluster

A similar scenario to that described above may occur when `override` is enabled and you use the Disconnect from Cluster option from the web-based manager or the `execute ha disconnect` command from the CLI to disconnect a cluster unit from a cluster.

Configuration changes made to the cluster can be lost when you reconnect the disconnected unit to the cluster. You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. Otherwise, when the disconnected unit joins the cluster, if `override` is enabled, the cluster renegotiates and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units and any configuration changes made between when the unit was disconnected and reconnected are lost.

Delaying how quickly the primary unit rejoins the cluster when override is enabled

In some cases when override is enabled and the unit designated to be the primary unit rejoins the cluster it will become the primary unit too soon and cause traffic disruption. This can happen, for example, if one of the FortiGate interfaces gets its address using PPPoE. If the backup unit is operating as the primary unit and processing traffic, when the primary unit comes up it may need a short time to get a new IP address from the PPPoE server. If the primary unit takes over the cluster before it has an IP address, traffic will be distrupted until the prinary unit gets its address.

You can resolve this problem by using the following command to add a wait time. In this example the wait time is 10 seconds. The wait time range is 0 to 3600 seconds and the default wait time is 0 seconds.

```
config system ha
   set override-wait-time 10
end
```

With this wait time configured, after the primary unit is up and running it has 10 seconds to synchronize sessions, get IP address(es) from PPPoE and DHCP servers and so on. After 10 seconds the primary unit sends gratiutious arp packets and all traffic to the cluster is sent to the new primary unit. You can adjust the wait time according to the conditions on your network.

FortiGate HA compatibility with DHCP and PPPoE

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving and incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

You cannot switch to operate in HA mode if one or more FortiGate unit interfaces is configured as a PPTP or L2TP client.

You can configure a cluster to act as a DHCP server or a DHCP relay agent. In both active-passive and active-active clusters DHCP relay sessions are always handled by the primary unit. It is possible that a DHCP relay session could be interrupted by a failover. If this occurs the DHCP relay session is not resumed after the failover and the DHCP client may have to repeat the DHCP request.

When a cluster is operating as a DHCP server the primary unit responds to all DHCP requests and maintains the DHCP server address lease database. The cluster also dynamically synchronizes the DHCP server address lease database to the subordinate units. If a failover occurs, the new primary unit will have an up-to-date DHCP server address lease database. Synchronizing the DHCP address lease database prevents the new primary unit from responding incorrectly to new DHCP requests after a failover.

Also, it is possible that when FortiGate units first negotiate to form a cluster that a unit that ends up as a subordinate unit in the cluster will have information in its DHCP address lease database that the cluster unit

operating as the primary unit does note have. This can happen if a FortiGate unit responds to DHCP requests while operating as a standalone unit and then when the cluster is formed this unit becomes a subordinate unit. Because of this possibility, after a cluster is formed the DHCP address lease databases of all of the cluster units are merged into one database which is then synchronized to all cluster units.

HA and distributed clustering

The FGCP supports widely separated cluster units installed in different physical locations. Distributed clusters can have cluster units in different rooms in the same building, different buildings in the same location, or even different geographical sites such as different cities, countries or continents.

Just like any cluster, distributed clusters require heartbeat communication between cluster units. In a distributed cluster this heartbeat communication can take place over the Internet or over other transmission methods including satellite linkups.

Because of the possible distance it may take a relatively long time for heartbeat packets to be transmitted between cluster units. To support a distributed cluster you may need to increase the heartbeat interval so that the cluster expects extra time between heartbeat packets. For information about changing the heartbeat interval and other heartbeat related settings, see Modifying heartbeat timing on page 1462.

Clusters of three or four FortiGate units

The FGCP supports a cluster of two, three, or four FortiGate units. You can add more than two units to a cluster to improve reliability: if two cluster units fail the third will continue to operate and so on. A cluster of three or four units in active-active mode may improve performance since another cluster unit is available for security profile processing. However, active-active FGCP HA results in diminishing performance returns as you add units to the cluster, so the additional performance achieved by adding the third cluster unit may not be worth the cost.

There are no special requirements for clusters of more than two units. Here are a few recommendations though:

- The matching heartbeat interfaces of all of the cluster units must be able to communicate with each other. So each unit's matching heartbeat interface should be connected to the same switch. If the ha1 interface is used for heartbeat communication, then the ha1 interfaces of all of the units in the cluster must be connected together so communication can happen between all of the cluster units over the ha1 interface.
- Redundant heartbeat interfaces are recommended. You can reduce the number of points of failure by connecting each matching set of heartbeat interfaces to a different switch. This is not a requirement; however, and you can connect both heartbeat interfaces of all cluster units to the same switch. However, if that switch fails the cluster will stop forwarding traffic.
- For any cluster, a dedicated switch for each heartbeat interface is recommended because of the large volume of heartbeat traffic and to keep heartbeat traffic off of other networks, but it is not required.
- Full mesh HA can scale to three or four FortiGate units. Full mesh HA is not required if you have more than 2 units in a cluster.
- Virtual clustering can only be done with two FortiGates.

Connecting a cluster of three FortiGate units

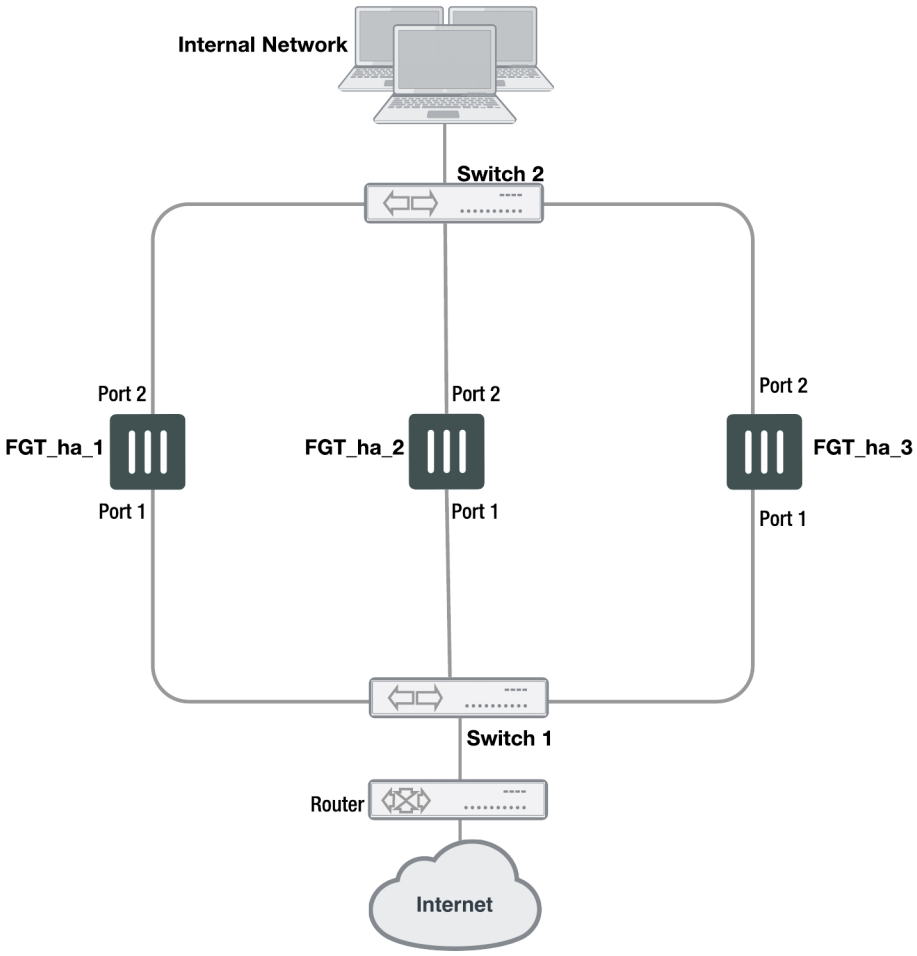
This example shows how to connect a cluster of three FortiGate units where:

- Port1 connects the cluster to the Internet
- Port2 connects the cluster to the internal network
- Port3 and Port4 are the heartbeat interfaces

Use the following steps to connect the cluster units to each other and to their networks:

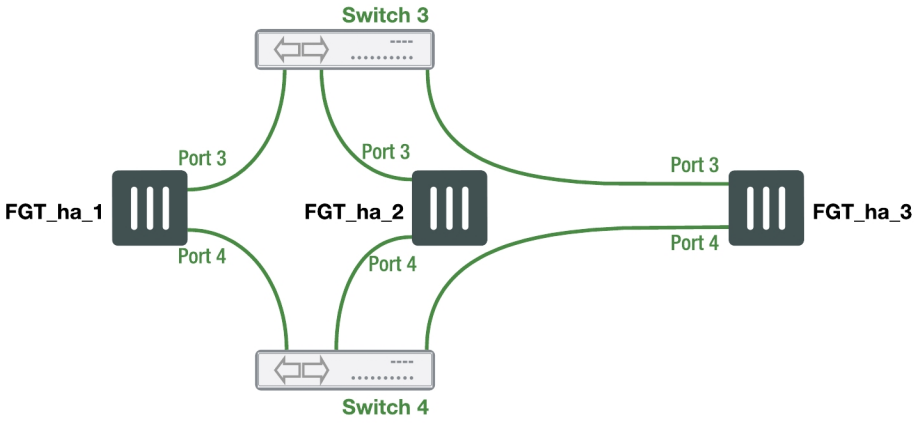
1. Connect the network interfaces:
   - Connect the port1 interface of each FortiGate unit to the same switch (Switch 1) and connect this switch to the Internet.
   - Connect the port2 interface of each FortiGate unit to the same switch (Switch 2) and connect this switch to the internal Network.

Connecting the network interfaces (cluster of three FortiGate units)



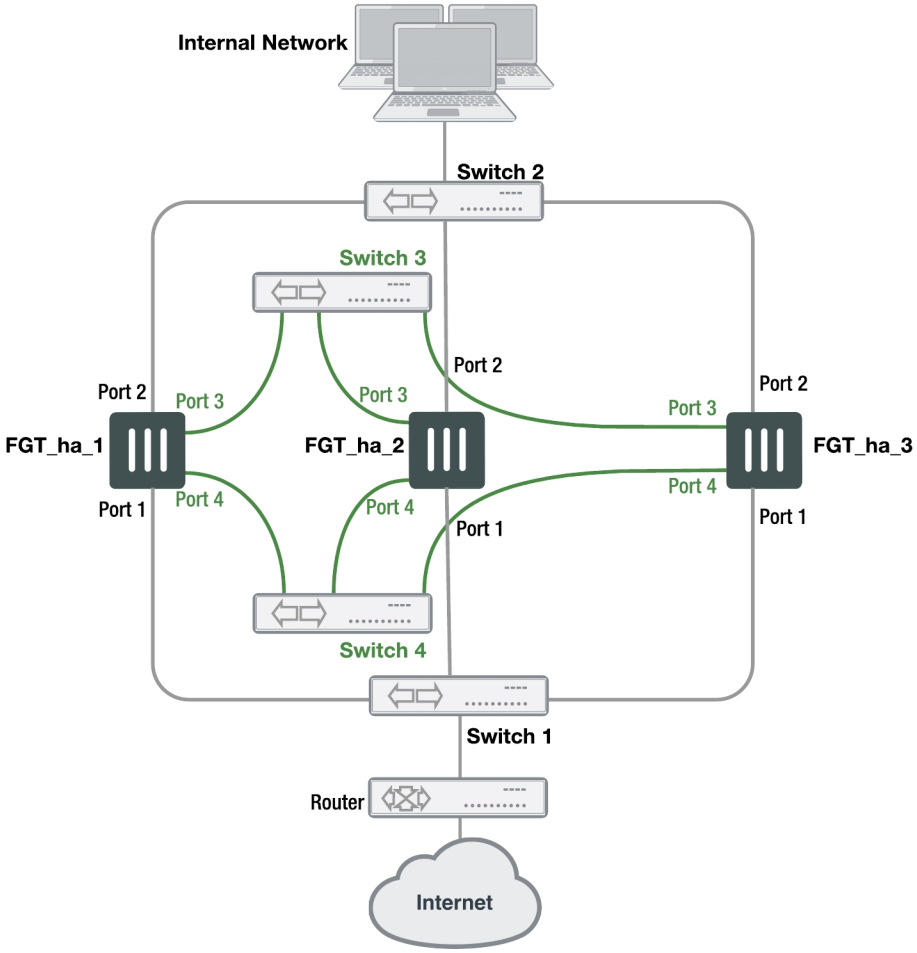
2. Connect the heartbeat interfaces:
   - Connect the port3 interface of each FortiGate unit to the same switch (Switch 3)
   - Connect the port4 interface of each FortiGate unit to the same switch (Switch 4)

Connecting the heartbeat interfaces (cluster of three FortiGate units)



The network and heartbeat connections when combined into one diagram appear like the following:

Network and heartbeat interface connections (cluster of three FortiGate units)



Disk storage configuration and HA

If your cluster units include storage disks (for example for storing log messages, WAN optimization data and web caching) all cluster units must have identical storage disk configurations. This means each cluster unit must have same number of disks (including AMC and FortiGate Storage Module (FSM) hard disks) and also means that matching disks in each cluster unit must be the same size, have the same format, and have the same number of partitions.

In most cases the default hard disk configuration of the cluster units will be compatible. However, a hard disk formatted by an older FortiGate firmware version may not be compatible with a hard disk formatted by a more recent firmware version. Problems may also arise if you have used the `execute scsi-dev` command to add or change hard disk protections.

If a cluster unit CLI displays hard disk compatibility messages, you may need to use the `execute scsi-dev delete` command to delete partitions. You can also use the `execute formatlogdisk` command to

reformat disks. In some cases after deleting all partitions and reformatting the disks, you may still see disk incompatibility messages. If this happens, contact Fortinet Customer Support for assistance.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
  - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See Enabling or disabling HA heartbeat encryption and authentication.
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NPx processor to avoid NPx-related problems from affecting heartbeat traffic.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.

- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See Remote link failover.

Troubleshooting

The following sections in this document contain troubleshooting information:

- FGCP configuration examples and troubleshooting on page 1313
- Troubleshooting virtual clustering on page 1406
- Troubleshooting full mesh HA on page 1419
- FortiGate VM for Hyper-V HA configuration on page 1524

FGCP HA terminology

The following HA-specific terms are used in this document.

Cluster

A group of FortiGate units that act as a single virtual FortiGate unit to maintain connectivity even if one of the FortiGate units in the cluster fails.

Cluster unit

A FortiGate unit operating in a FortiGate HA cluster.

Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

Failover

A FortiGate unit taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

Failure

A hardware or software problem that causes a FortiGate unit or a monitored interface to stop processing network traffic.

FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGate units in a cluster communicate to keep the cluster operating.

Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

Heartbeat device

An Ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGate units. Hello state may appear in HA log messages.

High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGate units in the cluster share session and configuration information.

Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see Link failover (port monitoring or interface monitoring).

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique similar to unicast load balancing. The primary unit interfaces are assigned virtual MAC addresses which are associated on the network with the cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule. Communication between the cluster units uses the actual cluster unit MAC addresses.

Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up.

Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

State synchronization

The part of the FGCP that maintains connections after failover.

Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

HA web-based manager options

Go to **System > Config > HA** to change HA options. You can set the following options to put a FortiGate unit into HA mode. You can also change any of these options while the cluster is operating.

You can configure HA options for a FortiGate unit with virtual domains (VDOMs) enabled by logging into the web-based manager as the global admin administrator and going to **System > Config > HA**.

If already operating in HA mode, go to **System > Config > HA to** display the cluster members list (see Cluster members list).

Go to **System > Config > HA** and select **View HA Statistics** to view statistics about cluster operation. See Viewing HA statistics.

If your cluster uses virtual domains, you are configuring HA virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see Virtual clusters on page 1387.

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

Mode

Select an HA mode for the cluster or return the FortiGate unit in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select **Standalone** (to disable HA), **Active-Passive**, or **Active-Active**.

If virtual domains are enabled you can select **Active-Passive** or **Standalone**.

Device Priority

Optionally set the device priority of the cluster FortiGate unit. Each FortiGate unit in a cluster can have a different device priority. During HA negotiation, the FortiGate unit with the highest device priority usually becomes the primary unit.

In a virtual cluster configuration, each cluster FortiGate unit can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate unit with the highest device priority in a virtual cluster becomes the primary FortiGate unit for that virtual cluster.

Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster.

Reserve Management Port for Cluster Member

You can provide direct management access to individual cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. See Managing individual cluster units using a reserved management interface.

Group Name

Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

Password

Enter a password to identify the cluster. The password must be the same for all cluster FortiGate units before the cluster FortiGate units can form a cluster.

Two clusters on the same network must have different passwords.

The password is synchronized to all cluster units in an operating cluster. If you change the password of one cluster unit the change is synchronized to all cluster units.

Enable Session pickup

Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit.

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. See Session failover (session pick-up).

Port Monitor

Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See Link failover (port monitoring or interface monitoring).

If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate unit that still has a connection to the network. This other cluster FortiGate unit becomes the new primary unit.

Port monitoring (also called interface monitoring) is disabled by default. Leave port monitoring disabled until the cluster is operating and then only enable port monitoring for connected interfaces.

You can monitor up to 64 interfaces.

Heartbeat Interface

Select to enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The web-based manager lists interfaces in alphanumeric order:

- port1
- port2 through 9
- port10

Hash map order sorts interfaces in the following order:

- port1
- port10
- port2 through port9

The default heartbeat interface configuration is different for each FortiGate model. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0.

You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See HA heartbeat and communication between cluster units.

You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.

VDOM partitioning

If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1.

FGCP high availability best practices

Fortinet suggests the following practices related to high availability:

- Use Active-Active HA to distribute TCP and UTM sessions among multiple cluster units. An active-active cluster may have higher throughput than a standalone FortiGate unit or than an active-passive cluster.
- Use a different host name on each FortiGate unit when configuring an HA cluster. Fewer steps are required to add host names to each cluster unit before configuring HA and forming a cluster.
- Consider adding an Alias to the interfaces used for the HA heartbeat so that you always get a reminder about what these interfaces are being used for.
- Enabling `load-balance-all` can increase device and network load since more traffic is load-balanced. This may be appropriate for use in a deployment using the firewall capabilities of the FortiGate unit and IPS but no other content inspection.
- An advantage of using session pickup is that non-content inspection sessions will be picked up by the new primary unit after a failover. The disadvantage is that the cluster generates more heartbeat traffic to support session pickup as a larger portion of the session table must be synchronized. Session pickup should be configured only when required and is not recommended for use with SOHO FortiGate models. Session pickup should only be used if the primary heartbeat link is dedicated (otherwise the additional HA heartbeat traffic could affect network performance).
- If session pickup is not selected, after a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Users downloading large files may have to restart their download after a failover. Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.

- If you need to enable session pickup, consider enabling session pickup delay to improve performance by reducing the number of sessions that are synchronized.
- Consider using the `session-sync-dev` option to move session synchronization traffic off the HA heartbeat link to one or more dedicated session synchronization interfaces.
- To avoid unpredictable results, when you connect a switch to multiple redundant or aggregate interfaces in an active-passive cluster you should configure separate redundant or aggregate interfaces on the switch; one for each cluster unit.
- Use SNMP, syslog, or email alerts to monitor a cluster for failover messages. Alert messages about cluster failovers may help find and diagnose network problems quickly and efficiently.

Heartbeat interfaces

Fortinet suggests the following practices related to heartbeat interfaces:

Do not use a FortiGate switch port for the HA heartbeat traffic. This configuration is not supported.

- For clusters of two FortiGate units, as much as possible, heartbeat interfaces should be directly connected using patch cables (without involving other network equipment such as switches). If switches have to be used they should not be used for other network traffic that could flood the switches and cause heartbeat delays.
  - If you cannot use a dedicated switch, the use of a dedicated VLAN can help limit the broadcast domain to protect the heartbeat traffic and the bandwidth it creates.
- For clusters of three or four FortiGate units, use switches to connect heartbeat interfaces. The corresponding heartbeat interface of each FortiGate unit in the cluster must be connected to the same switch. For improved redundancy use a different switch for each heartbeat interface. In that way if the switch connecting one of the heartbeat interfaces fails or is unplugged, heartbeat traffic can continue on the other heartbeat interfaces and switch.
- Isolate heartbeat interfaces from user networks. Heartbeat packets contain sensitive cluster configuration information and can consume a considerable amount of network bandwidth. If the cluster consists of two FortiGate units, connect the heartbeat interfaces directly using a crossover cable or a regular Ethernet cable. For clusters with more than two units, connect heartbeat interfaces to a separate switch that is not connected to any network.
- If heartbeat traffic cannot be isolated from user networks, enable heartbeat message encryption and authentication to protect cluster information. See Enabling or disabling HA heartbeat encryption and authentication.
- Configure and connect redundant heartbeat interfaces so that if one heartbeat interface fails or becomes disconnected, HA heartbeat traffic can continue to be transmitted using the backup heartbeat interface. If heartbeat communication fails, all cluster members will think they are the primary unit resulting in multiple devices on the network with the same IP addresses and MAC addresses (condition referred to as *Split Brain*) and communication will be disrupted until heartbeat communication can be reestablished.
- Do not monitor dedicated heartbeat interfaces; monitor those interfaces whose failure should trigger a device failover.
- Where possible at least one heartbeat interface should not be connected to an NPx processor to avoid NPx-related problems from affecting heartbeat traffic.

Interface monitoring (port monitoring)

Fortinet suggests the following practices related to interface monitoring (also called port monitoring):

- Wait until a cluster is up and running and all interfaces are connected before enabling interface monitoring. A monitored interface can easily become disconnected during initial setup and cause failovers to occur before the cluster is fully configured and tested.
- Monitor interfaces connected to networks that process high priority traffic so that the cluster maintains connections to these networks if a failure occurs.
- Avoid configuring interface monitoring for all interfaces.
- Supplement interface monitoring with remote link failover. Configure remote link failover to maintain packet flow if a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails. See Remote link failover.

FGCP HA terminology

The following HA-specific terms are used in this document.

Cluster

A group of FortiGate units that act as a single virtual FortiGate unit to maintain connectivity even if one of the FortiGate units in the cluster fails.

Cluster unit

A FortiGate unit operating in a FortiGate HA cluster.

Device failover

Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

Failover

A FortiGate unit taking over processing network traffic in place of another unit in the cluster that suffered a device failure or a link failure.

Failure

A hardware or software problem that causes a FortiGate unit or a monitored interface to stop processing network traffic.

FGCP

The FortiGate clustering protocol (FGCP) that specifies how the FortiGate units in a cluster communicate to keep the cluster operating.

Full mesh HA

Full mesh HA is a method of removing single points of failure on a network that includes an HA cluster. FortiGate models that support redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA includes redundant connections between all network components. If any single component or any single connection fails, traffic switches to the redundant component or connection.

HA virtual MAC address

When operating in HA mode, all of the interfaces of the primary unit acquire the same HA virtual MAC address. All communications with the cluster must use this MAC address. The HA virtual MAC address is set according to the group ID.

Heartbeat

Also called FGCP heartbeat or HA heartbeat. The heartbeat constantly communicates HA status and synchronization information to make sure that the cluster is operating properly.

Heartbeat device

An Ethernet network interface in a cluster that is used by the FGCP for heartbeat communications among cluster units.

Heartbeat failover

If an interface functioning as the heartbeat device fails, the heartbeat is transferred to another interface also configured as an HA heartbeat device.

Hello state

In the hello state a cluster unit has powered on in HA mode, is using HA heartbeat interfaces to send hello packets, and is listening on its heartbeat interfaces for hello packets from other FortiGate units. Hello state may appear in HA log messages.

High availability

The ability that a cluster has to maintain a connection when there is a device or link failure by having another unit in the cluster take over the connection, without any loss of connectivity. To achieve high availability, all FortiGate units in the cluster share session and configuration information.

Interface monitoring

You can configure interface monitoring (also called port monitoring) to monitor FortiGate interfaces to verify that the monitored interfaces are functioning properly and connected to their networks. If a monitored interface fails or is disconnected from its network the interface leaves the cluster and a link failover occurs. For more information about interface monitoring, see Link failover (port monitoring or interface monitoring).

Link failover

Link failover means that if a monitored interface fails, the cluster reorganizes to re-establish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

Load balancing

Also known as active-active HA. All units in the cluster process network traffic. The FGCP employs a technique similar to unicast load balancing. The primary unit interfaces are assigned virtual MAC addresses which are

associated on the network with the cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit can process packets itself, or propagate them to subordinate units according to a load balancing schedule. Communication between the cluster units uses the actual cluster unit MAC addresses.

Monitored interface

An interface that is monitored by a cluster to make sure that it is connected and operating correctly. The cluster monitors the connectivity of this interface for all cluster units. If a monitored interface fails or becomes disconnected from its network, the cluster will compensate.

Primary unit

Also called the primary cluster unit, this cluster unit controls how the cluster operates. The primary unit sends hello packets to all cluster units to synchronize session information, synchronize the cluster configuration, and to synchronize the cluster routing table. The hello packets also confirm for the subordinate units that the primary unit is still functioning.

The primary unit also tracks the status of all subordinate units. When you start a management connection to a cluster, you connect to the primary unit.

In an active-passive cluster, the primary unit processes all network traffic. If a subordinate unit fails, the primary unit updates the cluster configuration database.

In an active-active cluster, the primary unit receives all network traffic and re-directs this traffic to subordinate units. If a subordinate unit fails, the primary unit updates the cluster status and redistributes load balanced traffic to other subordinate units in the cluster.

The FortiGate firmware uses the term master to refer to the primary unit.

Session failover

Session failover means that a cluster maintains active network sessions after a device or link failover. FortiGate HA does not support session failover by default. To enable session failover you must change the HA configuration to select Enable Session Pick-up.

Session pickup

If you enable session pickup for a cluster, if the primary unit fails or a subordinate unit in an active-active cluster fails, all communication sessions with the cluster are maintained or picked up by the cluster after the cluster negotiates to select a new primary unit.

If session pickup is not a requirement of your HA installation, you can disable this option to save processing resources and reduce the network bandwidth used by HA session synchronization. In many cases interrupted sessions will resume on their own after a failover even if session pickup is not enabled. You can also enable session pickup delay to reduce the number of sessions that are synchronized by session pickup.

Standby state

A subordinate unit in an active-passive HA cluster operates in the standby state. In a virtual cluster, a subordinate virtual domain also operates in the standby state. The standby state is actually a hot-standby state because the

subordinate unit or subordinate virtual domain is not processing traffic but is monitoring the primary unit session table to take the place of the primary unit or primary virtual domain if a failure occurs.

In an active-active cluster all cluster units operate in a work state.

When standby state appears in HA log messages this usually means that a cluster unit has become a subordinate unit in an active-passive cluster or that a virtual domain has become a subordinate virtual domain.

State synchronization

The part of the FGCP that maintains connections after failover.

Subordinate unit

Also called the subordinate cluster unit, each cluster contains one or more cluster units that are not functioning as the primary unit. Subordinate units are always waiting to become the primary unit. If a subordinate unit does not receive hello packets from the primary unit, it attempts to become the primary unit.

In an active-active cluster, subordinate units keep track of cluster connections, keep their configurations and routing tables synchronized with the primary unit, and process network traffic assigned to them by the primary unit. In an active-passive cluster, subordinate units do not process network traffic. However, active-passive subordinate units do keep track of cluster connections and do keep their configurations and routing tables synchronized with the primary unit.

The FortiGate firmware uses the terms slave and subsidiary unit to refer to a subordinate unit.

Virtual clustering

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Work state

The primary unit in an active-passive HA cluster, a primary virtual domain in a virtual cluster, and all cluster units in an active-active cluster operate in the work state. A cluster unit operating in the work state processes traffic, monitors the status of the other cluster units, and tracks the session table of the cluster.

When work state appears in HA log messages this usually means that a cluster unit has become the primary unit or that a virtual domain has become a primary virtual domain.

HA GUI options

Go to **System > Config > HA** to change HA options. You can set the following options to put a FortiGate unit into HA mode. You can also change any of these options while the cluster is operating.

You can configure HA options for a FortiGate unit with virtual domains (VDOMs) enabled by logging into the web-based manager as the global admin administrator and going to **System > Config > HA**.

If already operating in HA mode, go to **System > Config > HA to** display the cluster members list (see Cluster members list).

Go to **System > Config > HA** and select **View HA Statistics** to view statistics about cluster operation. See Viewing HA statistics.

If your cluster uses virtual domains, you are configuring HA virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below and see Virtual clusters on page 1387.

FortiGate HA is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. If an interface is configured for DHCP or PPPoE, turning on high availability may result in the interface receiving an incorrect address or not being able to connect to the DHCP or PPPoE server correctly.

Mode

Select an HA mode for the cluster or return the FortiGate unit in the cluster to standalone mode. When configuring a cluster, you must set all members of the HA cluster to the same HA mode. You can select **Standalone** (to disable HA), **Active-Passive**, or **Active-Active**.

If virtual domains are enabled you can select **Active-Passive** or **Standalone**.

Device Priority

Optionally set the device priority of the cluster FortiGate unit. Each FortiGate unit in a cluster can have a different device priority. During HA negotiation, the FortiGate unit with the highest device priority usually becomes the primary unit.

In a virtual cluster configuration, each cluster FortiGate unit can have two different device priorities, one for each virtual cluster. During HA negotiation, the FortiGate unit with the highest device priority in a virtual cluster becomes the primary FortiGate unit for that virtual cluster.

Changes to the device priority are not synchronized. You can accept the default device priority when first configuring a cluster.

Reserve Management Port for Cluster Member

You can provide direct management access to individual cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. See Managing individual cluster units using a reserved management interface.

Do NOT Synchronize Management VDOM Configuration

This options appears if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can select this option to prevent the management VDOM configuration from being synchronized between cluster units in the virtual cluster. This allows you to add an interface to the VDOM in each cluster unit and then to give the Interfacea different IP address in each cluster unit, allowing you to manage eachc cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
   set standalone-mgmt-vdom enable
end
```

Group Name

Enter a name to identify the cluster. The maximum length of the group name is 32 characters. The group name must be the same for all cluster units before the cluster units can form a cluster. After a cluster is operating, you can change the group name. The group name change is synchronized to all cluster units.

Password

Enter a password to identify the cluster. The password must be the same for all cluster FortiGate units before the cluster FortiGate units can form a cluster.

Two clusters on the same network must have different passwords.

The password is synchronized to all cluster units in an operating cluster. If you change the password of one cluster unit the change is synchronized to all cluster units.

Enable Session pickup

Select to enable session pickup so that if the primary unit fails, sessions are picked up by the cluster unit that becomes the new primary unit.

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce HA CPU usage and reduce HA heartbeat network bandwidth usage. See Session failover (session pick-up).

Port Monitor

Select to enable or disable monitoring FortiGate interfaces to verify the monitored interfaces are functioning properly and are connected to their networks. See Link failover (port monitoring or interface monitoring).

If a monitored interface fails or is disconnected from its network, the interface leaves the cluster and a link failover occurs. The link failover causes the cluster to reroute the traffic being processed by that interface to the same interface of another cluster FortiGate unit that still has a connection to the network. This other cluster FortiGate unit becomes the new primary unit.

Port monitoring (also called interface monitoring) is disabled by default. Leave port monitoring disabled until the cluster is operating and then only enable port monitoring for connected interfaces.

You can monitor up to 64 interfaces.

Heartbeat Interface

Select to enable or disable HA heartbeat communication for each interface in the cluster and set the heartbeat interface priority. The heartbeat interface with the highest priority processes all heartbeat traffic. If two or more heartbeat interfaces have the same priority, the heartbeat interface with the lowest hash map order value processes all heartbeat traffic. The web-based manager lists interfaces in alphanumeric order:

- port1
- port2 through 9
- port10

Hash map order sorts interfaces in the following order:

- port1
- port10
- port2 through port9

The default heartbeat interface configuration is different for each FortiGate model. This default configuration usually sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration or change it as required.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0.

You must select at least one heartbeat interface. If heartbeat communication is interrupted, the cluster stops processing traffic. See HA heartbeat and communication between cluster units.

You can select up to 8 heartbeat interfaces. This limit only applies to units with more than 8 physical interfaces.

VDOM partitioning

If you are configuring virtual clustering, you can set the virtual domains to be in virtual cluster 1 and the virtual domains to be in virtual cluster 2. The root virtual domain must always be in virtual cluster 1.

FGCP configuration examples and troubleshooting

This chapter contains general procedures and descriptions as well as detailed configuration examples that describe how to configure FortiGate HA clusters.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameter

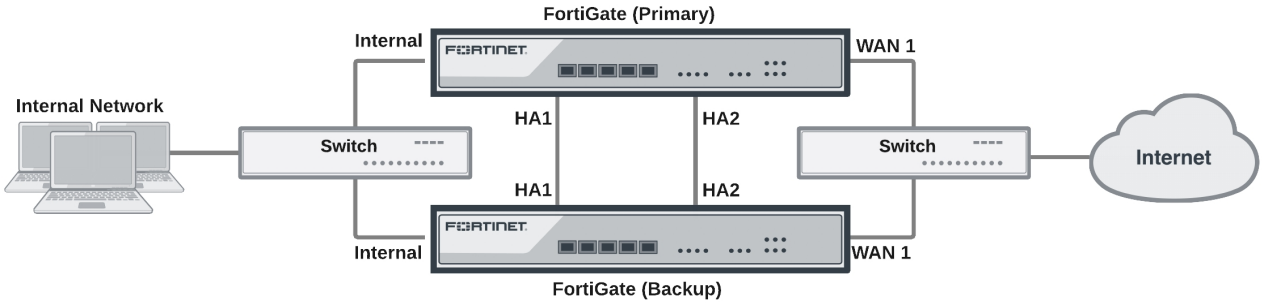
About the examples in this chapter

The procedures in this chapter describe some of many possible sequences of steps for configuring HA clustering. As you become more experienced with FortiOS HA you may choose to use a different sequence of configuration steps.

For simplicity, many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

How to set up FGCP clustering (recommended steps)

This example describes how to enhance the reliability of a network protected by a FortiGate unit by adding a second FortiGate unit to create a FortiGate Clustering Protocol (FGCP) High Availability cluster.



The FortiGate already on the network will be configured to become the primary unit by increasing its device priority and enabling override. The new FortiGate will be prepared by setting it to factory defaults to wipe any configuration changes. Then it will be licensed, configured for HA, and then connected to the FortiGate already on the network. The new FortiGate becomes the backup unit and its configuration is overwritten by the primary unit.

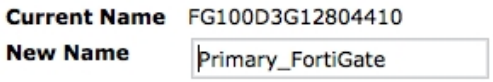
The recipe contains instructions for both the GUI and the CLI, with some parts of the configuration requiring use of the CLI.

Before you start the FortiGates should be running the same FortiOS firmware version and interfaces should not be configured to get their addresses from DHCP or PPPoE.

1. Configuring the primary FortiGate

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

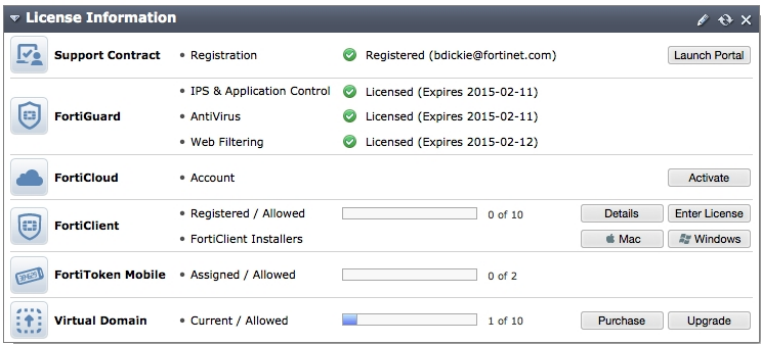
Connect to the primary FortiGate and go to **System > Dashboard > Status** and locate the **System Information** widget. Change the unit's **Host Name** to identify it as the primary FortiGate.



You can also enter this CLI command:

```
config system global
  set hostname Primary_FortiGate
end
```

If you have not already done so, register the primary FortiGate and apply licenses to it before setting up the cluster. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMs). You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate. FortiToken licenses can be added at any time because they are synchronized to all cluster members.



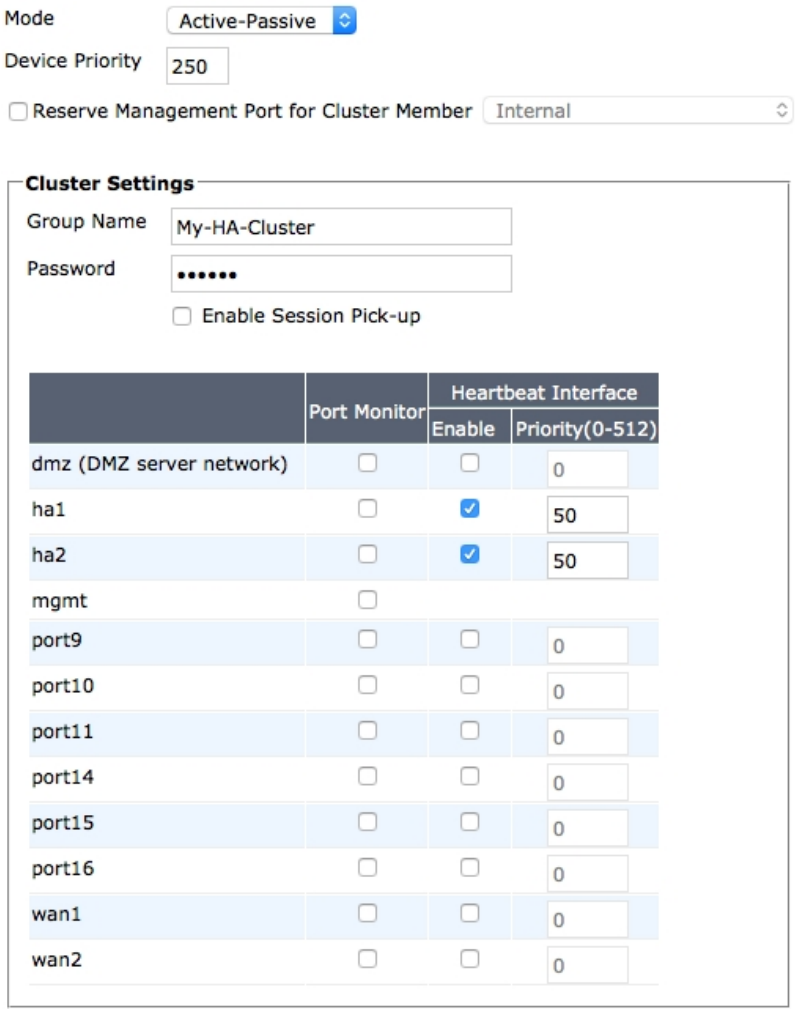
Enter this CLI command to set the HA mode to active-passive, set a group name and password, increase the device priority to a higher value (for example, 250) and enable override.

```
config system ha
  set mode a-p
  set group-name My-HA-Cluster
  set password
  set priority 250
  set override enable
  set hbdev ha1 50 ha2 50
end
```

Enabling override and increasing the device priority means this unit should always become the primary unit.

This command also selects ha1 and ha2 to be the heartbeat interfaces and sets their priorities to 50.

You can also use the GUI to configure most of these settings.



Override can only be enabled from the CLI.

```
config system ha
   set override enable
end
```

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as FGCP negotiation takes place and the MAC addresses of the FortiGate unit are changed to HA virtual MAC addresses. These virtual MAC addresses are used for failover. The actual virtual MAC address assigned to each FortiGate interface depends on the HA group ID. Since this example does not involved changing the HA group ID, the FortiGate unit's interfaces will have the following MAC addresses: 00:09:0f:09:00:00, 00:09:0f:09:00:01, 00:09:0f:09:00:02 and so on.

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You can usually delete the arp table from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) command to view the virtual MAC address of any FortiGate unit interface. Depending on the FortiGate model, the output from this command could include lines similar to the following:

```
Current_HWaddr: 00:09:0f:09:00:00
Permanent_HWaddr 02:09:0f:78:18:c9
```

2. Configuring the backup FortiGate

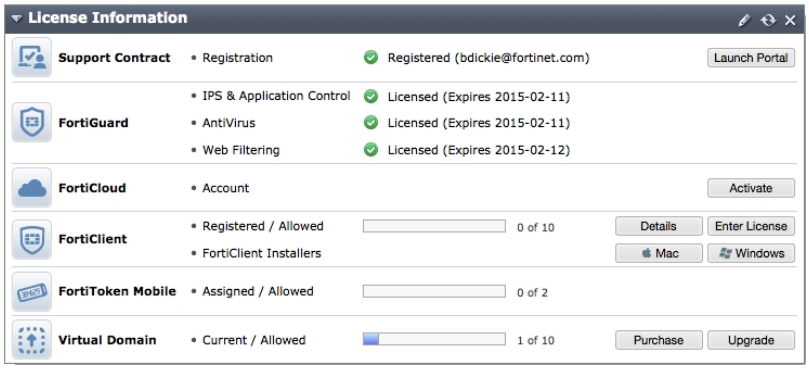
Enter this command to reset the new FortiGate to factory default settings.

```
execute factoryreset
```

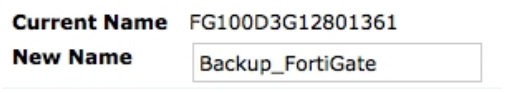
You can skip this step if the new FortiGate is fresh from the factory. But if its configuration has been changed at all it is recommended to set it back to factory defaults to reduce the chance of synchronization problems.

Change the firmware running on the new FortiGate to be the same version as is running on the primary unit.

Register the backup FortiGate and apply licenses to it before adding it to the cluster. This includes **FortiCloud** activation, **FortiClient** licensing and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMs). FortiToken licenses can be added at any time because they are synchronized to all cluster members.



Go to **System > Dashboard > Status** and change the unit's **Host Name** to identify it as the backup FortiGate.

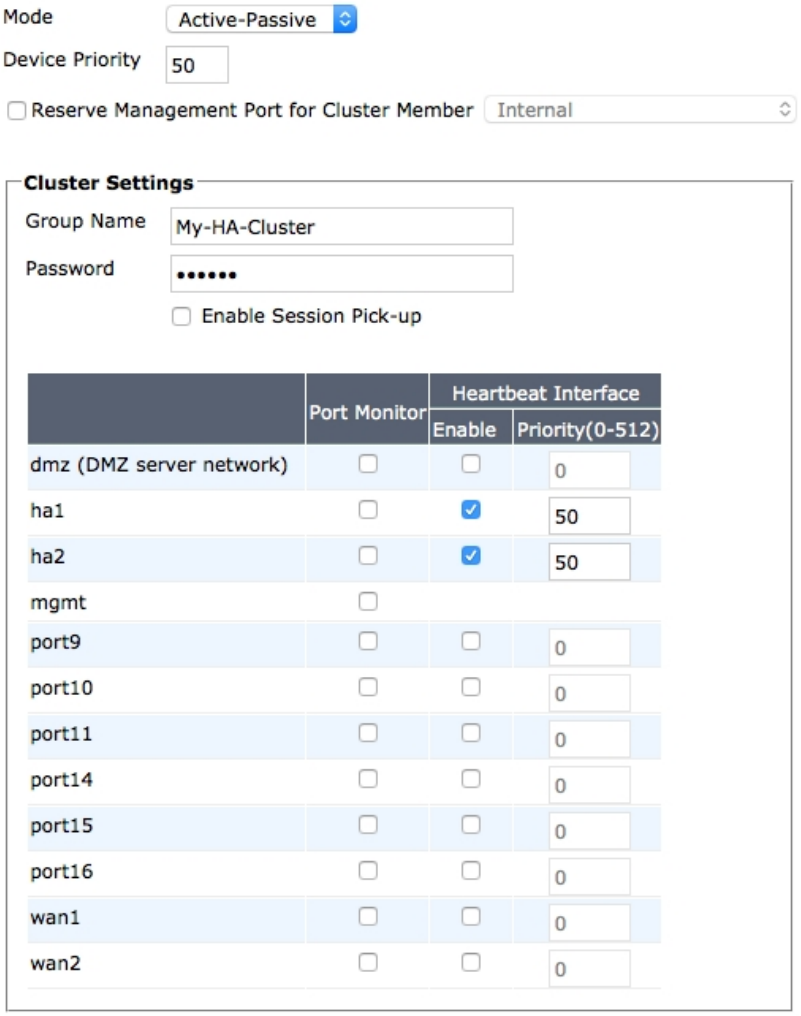


You can also enter this CLI command:

```
config system global
   set hostname Backup_FortiGate
end
```

Duplicate the primary unit HA settings, except set the device priority to a lower value and do not enable override.

You can configure all of these settings from the GUI.



You can also enter this CLI command:

```
config system ha
   set mode a-p
   set group-name My-HA-Cluster
   set password
   set priority 50
   set hbdev ha1 50 ha2 50
end
```

3. Connecting the cluster

Connect the HA cluster as shown in the initial diagram. Making these connections will disrupt network traffic as you disconnect and re-connect cables.

When connected the primary and backup FortiGates find each other and negotiate to form an HA cluster. The Primary unit synchronizes its configuration with the backup FortiGate. Forming the cluster happens automatically with minimal or no disruption to network traffic.

4. Checking cluster operation and disabling override

Check the cluster synchronization status to make sure the primary and backup units have the same configuration. Log into the primary unit CLI and enter this command:

```
diag sys ha cluster-csum
```

The CLI lists all members' checksums. If both cluster units have identical checksums you can be sure that their configurations are synchronized. If the checksums are different wait a short while and enter the command again. Repeat until the checksums are identical. It may take a while for some parts of the configuration to be synchronized. If the checksums never become identical contact Fortinet support to help troubleshoot the problem.

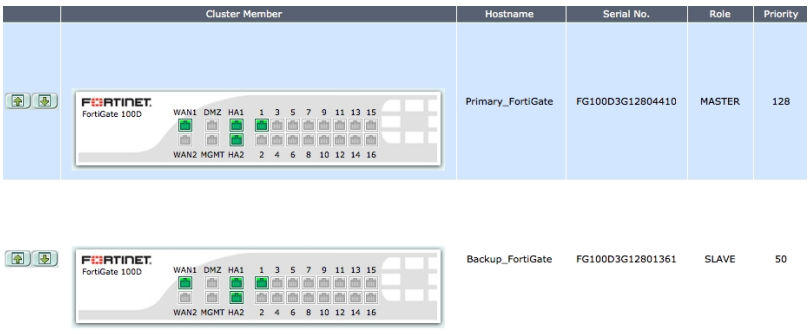
Disable override on the primary unit (recommended).

```
config system ha
    set override disable
end
```

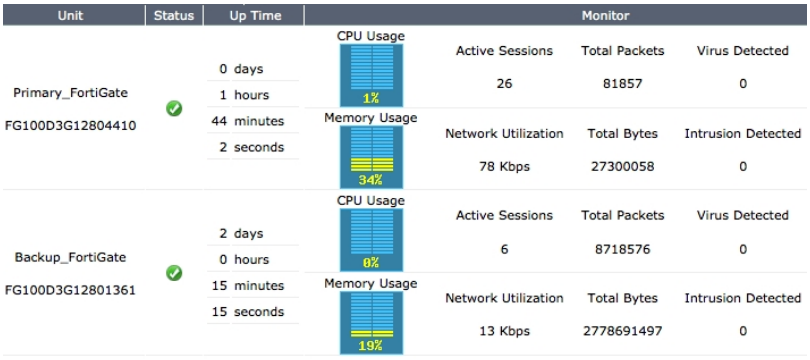
The HA cluster dynamically responds to network conditions. If you keep override enabled the same FortiGate will always be the primary FortiGate. Because of this, however; the cluster may negotiate more often potentially disrupting traffic.

If you disable override it is more likely that the new FortiGate unit could become the primary unit. Disabling override is recommended unless its important that the same FortiGate remains the primary unit.

Connect to the primary FortiGate GUI and go to **System > Config > HA** to view the cluster information.



Select **View HA Statistics** for more information on how the cluster is operating and processing traffic.



5. Results

Normally, traffic should now be flowing through the primary FortiGate. However, if the primary FortiGate is unavailable, traffic should failover and the backup FortiGate will be used. Failover will also cause the primary and backup FortiGates to reverse roles, even when both FortiGates are available again.

To test this, ping the IP address 8.8.8.8 using a PC on the internal network. After a moment, power off the primary FortiGate.

```
Reply from 8.8.8.8: bytes=32 time=50ms TTL=53
Reply from 8.8.8.8: bytes=32 time=38ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Request timed out.
Reply from 8.8.8.8: bytes=32 time=482ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Reply from 8.8.8.8: bytes=32 time=36ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Reply from 8.8.8.8: bytes=32 time=38ms TTL=53
```

You will see a momentary pause in the Ping results, until traffic diverts to the backup FortiGate, allowing the Ping traffic to continue.

If you are using port monitoring, you can also unplug the primary FortiGate's Internet-facing interface to test failover.

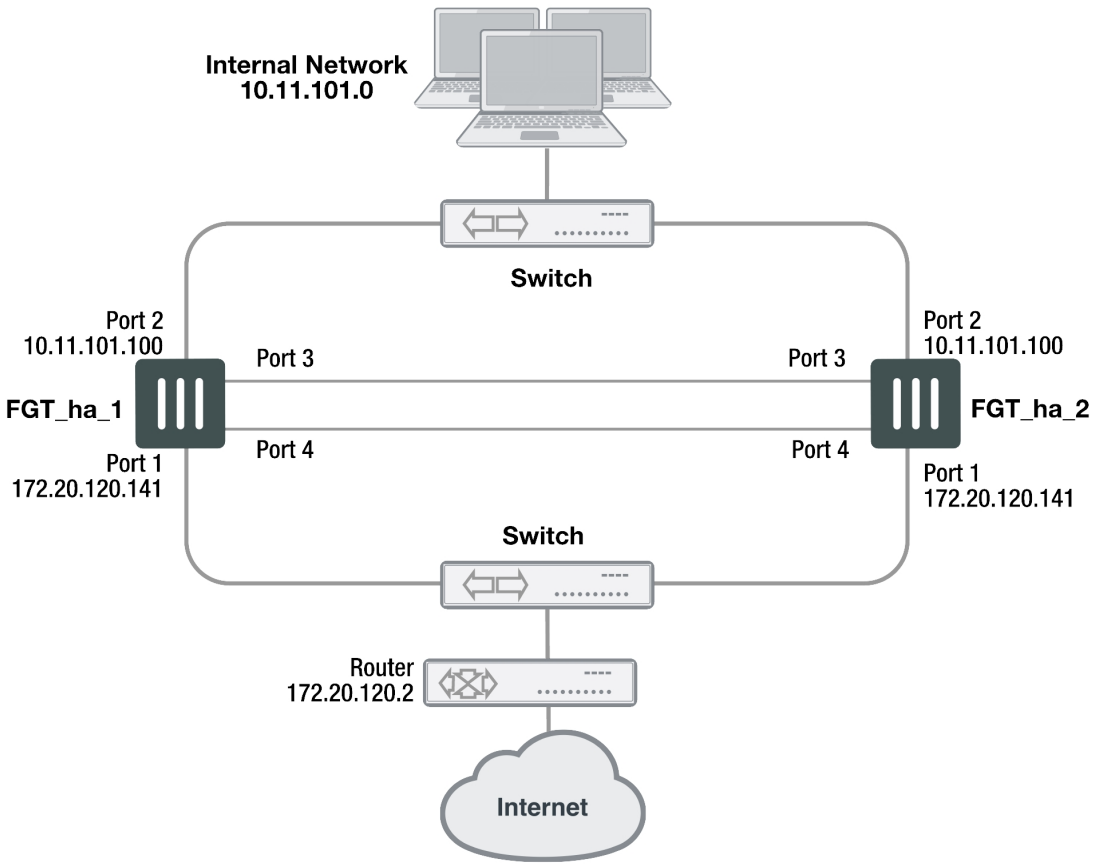
Setting up two new FortiGates as an FGCP cluster

This section describes a simple HA network topology that includes an HA cluster of two FortiGate units in NAT/Route mode installed between an internal network and the Internet. The example uses a generic FortiGate unit with four interfaces named port1, port2, port3 and port4.

Example NAT/Route mode HA network topology

The figure below shows a typical FortiGate HA cluster consisting of two FortiGate units (FGT_ha_1 and FGT_ha_2) connected to the same internal (port2) and external (port1) networks.

Example NAT/Route mode HA network topology



Port3 and port4 are used as the heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGate units to become the cluster.
2. Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster and add basic configuration settings to the cluster.

- View cluster status from the web-based manager or CLI.
- Add a password for the admin administrative account.
- Change the IP addresses and netmasks of the internal and external interfaces.
- Add a default route.

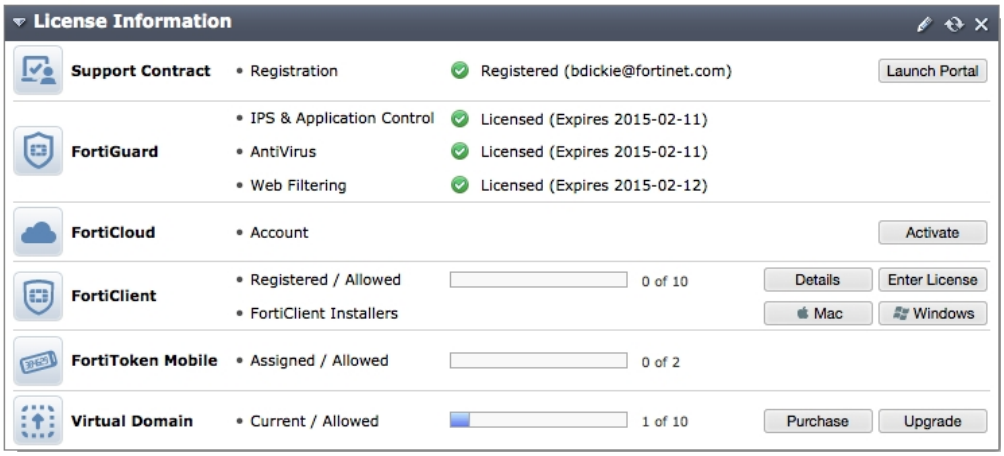
Configuring a NAT/Route mode active-passive cluster of two FortiGate units - web-based manager

Use the following procedures to configure two FortiGate units for NAT/Route HA operation using the web-based manager. These procedures assume you are starting with two FortiGate units with factory default settings.

Give each cluster unit a unique host name to make the individual units easier to identify when they are part of a functioning cluster. The default host name is the FortiGate serial number. You may want to change this host name to something more meaningful for your network.

To configure the first FortiGate unit (host name FGT_ha_1)

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget beside **Host Name**, select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Select **OK**.
6. Go to **System > Config > HA** and change the following settings:

Mode	Active-Passive
Group Name	example1.com
Password	HA_pass_1

This is the minimum recommended configuration for an active-passive HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each unit in the cluster.

7. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:
   - port1 interface virtual MAC: `00-09-0f-09-00-00`
   - port2 interface virtual MAC: `00-09-0f-09-00-01`
   - port3 interface virtual MAC: `00-09-0f-09-00-02`
   - port4 interface virtual MAC: `00-09-0f-09-00-03`

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

   To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

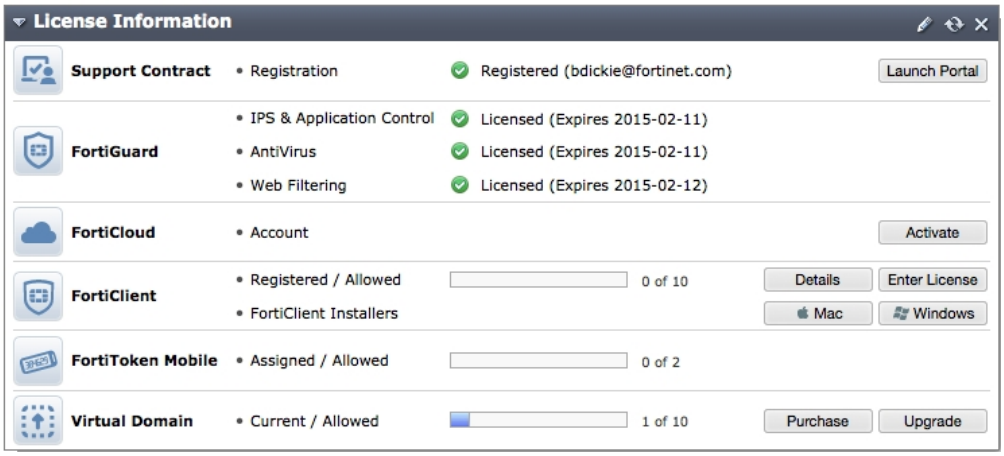
```
get hardware nic port1
.
.
.
Current_HWaddr:  00:09:0f:09:00:00
Permanent_HWaddr  02:09:0f:78:18:c9
.
.
.
```

10. Power off the first FortiGate unit (FGT_ha_1).

Note the details and format of the output of the `get hardware nic` command are specific to the interface hardware. Different FortiGate models and even different interfaces in the same FortiGate unit may have different output.

To configure the second FortiGate unit (host name FGT_ha_2)

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_2

4. Select **OK**.
5. Go to **System > Config > HA** and change the following settings:

Mode	Active-Passive
Group Name	example1.com
Password	HA_pass_1

6. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
7. Power off the second FortiGate unit.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation

occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address https://192.168.1.99 (remember to include the “s” in https://).
   The FortiGate Login is displayed.
2. Type `admin` in the **Name** field and select Login.
   The FortiGate dashboard is displayed.
   The **System Information** dashboard widget shows the **Cluster Name** (example1.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
3. Go to **System > Config > HA** to view the cluster members list.
   The list shows both cluster units, their host names, their roles in the cluster, and their device priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See Setting up two new FortiGates as an FGCP cluster on page 1319 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster to connect to its network. The following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **System > Network > Interfaces**.
7. Edit the **port2** interface and change **IP/Netmask** to 10.11.101.100/24.
8. Select **OK**.

After changing the IP address of the port1 interface you may have to change the IP address of your management computer and then reconnect to the port1 interface using the 172.20.120.141 IP address.

9. Edit the **port1** interface and change **IP/Netmask** to 172.20.120.141/24.
10. Select **OK**.
11. Go to **Router > Static > Static Routes**.
12. Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port1
Distance	10

13. Select **OK**.

Configuring a NAT/Route mode active-passive cluster of two FortiGate units - CLI

Use the following procedures to configure two FortiGate units for NAT/Route HA operation using the FortiGate CLI. These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the first FortiGate unit (host name FGT_ha_1)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal (or any terminal emulation program), enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
   The FortiGate unit CLI login prompt appears.
   If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
9. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.

FortiToken licenses can be added at any time because they are synchronized to all cluster members.

10. Change the host name for this FortiGate unit.

```
config system global
   set hostname FGT_ha_1
end
```

11. Configure HA settings.

```
config system ha
   set mode a-p
   set group-name example1.com
   set password HA_pass_1
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port2 interface virtual MAC: `00-09-0f-09-00-01`
- port3 interface virtual MAC: `00-09-0f-09-00-02`
- port4 interface virtual MAC: `00-09-0f-09-00-03`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr  02:09:0f:78:18:c9
.
.
.
```

10. Display the HA configuration (optional).

```
get system ha
   group-id : 0
   group-name : example1.com
   mode : a-p
   password : *
   hbdev : "port3" 50 "port4" 50
   session-sync-dev    :
   route-ttl : 10
   route-wait : 0
   route-hold : 10
   sync-config : enable
   encryption : disable
   authentication : disable
```

```
hb-interval : 2
hb-lost-threshold : 20
helo-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
slave-switch-standby: disable
minimum-worker-threshold: 1
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"
```

11. Power off the FortiGate unit.

To configure the second FortiGate unit (host name FGT_ha_2)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
   The FortiGate unit CLI login prompt appears.
7. Type `admin` and press **Enter** twice.

8. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activationand **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
9. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
10. Change the host name for this FortiGate unit.

```
config system global
   set hostname FGT_ha_2
end
```

11. Configure HA settings.

```
config system ha
   set mode a-p
   set group-name example1.com
   set password HA_pass_1
end
```

   The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

12. Display the HA configuration (optional).

```
get system ha
   group-id : 0
   group-name : example1.com
   mode : a-p
   password : *
   hbdev : "port3" 50 "port4" 50
   session-sync-dev    :
   route-ttl : 10
   route-wait : 0
   route-hold : 10
   sync-config : enable
   encryption : disable
   authentication : disable
   hb-interval : 2
   hb-lost-threshold : 20
   helo-holddown : 20
   arps : 5
   arps-interval : 8
   session-pickup : disable
   update-all-session-timer: disable
   session-sync-daemon-number: 1
   link-failed-signal : disable
   uninterruptible-upgrade: enable
   ha-mgmt-status : disable
   ha-eth-type : 8890
   hc-eth-type : 8891
   l2ep-eth-type : 8893
   ha-uptime-diff-margin: 300
   vcluster2 : disable
   vcluster-id : 1
```

```
override : disable
priority : 128
slave-switch-standby: disable
minimum-worker-threshold: 1
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"
```

13. Power off the FortiGate unit.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.
   - Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
   - Enter the command `get system status`.
   - If the command output includes `Current HA mode: a-p, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step "Setting up two new FortiGates as an FGCP cluster" on page 1319.
   - If the command output includes `Current HA mode: a-p, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
   Model: XXXXX
   Mode: a-p
   Group: 0
   Debug: 0
   ses_pickup: disable
```

```
Master:128 FGT_ha_2 FG600B3908600825 0
Slave :128 FGT_ha_1 FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

3. Check the cluster synchronization status to make sure the primary and backup units have the same configuration. Log into the primary unit CLI and enter this command:

```
diag sys ha cluster-csum
```

The CLI lists all members' checksums. If both cluster units have identical checksums you can be sure that their configurations are synchronized. If the checksums are different wait a short while and enter the command again. Repeat until the checksums are identical. It may take a while for some parts of the configuration to be synchronized. If the checksums never become identical contact Fortinet support to help troubleshoot the problem.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See Setting up two new FortiGates as an FGCP cluster on page 1319 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to add some basic settings to the cluster so that it can connect to the network.

1. Log into the primary unit CLI.
2. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <password_str>
end
```

3. Configure the port1 and port2 interfaces.

```
config system interface
   edit port1
      set ip 172.20.120.141/24
   next
   edit port2
      set ip 10.11.101.100/24
end
```

4. Add a default route.

```
config router static
   edit 1
      set dst 0.0.0.0 0.0.0.0
      set gateway 172.20.120.2
      set device port1
end
```

Adding a new FortiGate to an operating cluster

This procedure describes how to add a new FortiGate unit to a functioning cluster. Adding a new unit to a cluster does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the new cluster unit.

You can use this procedure to add as many units as required to the cluster.

To add a new unit to a functioning cluster

1. Install the same firmware build on the new cluster unit as is running on the cluster.
2. Register and apply licenses to the new cluster unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. Configure the new cluster unit for HA operation with the same HA configuration as the other units in the cluster.
4. If the cluster is running in Transparent mode, change the operating mode of the new cluster unit to Transparent mode.
5. Power off the new cluster unit.
6. Connect the new cluster unit to the cluster.
7. For example, see How to set up FGCP clustering (recommended steps) on page 1313.
8. Power on the new cluster unit.

   When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the new unit configuration with the configuration of the primary unit.

You can add a new unit to a functioning cluster at any time. The new cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

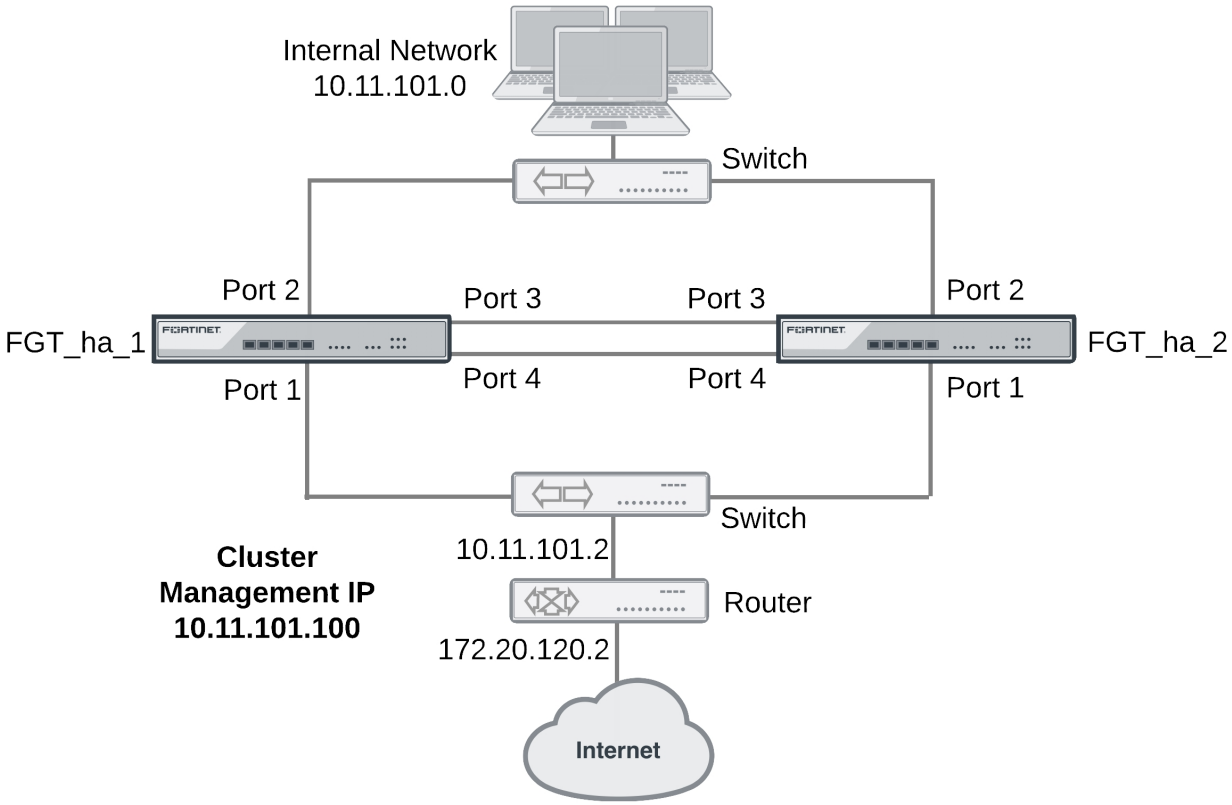
Active-active HA cluster in Transparent mode

This section describes a simple HA network topology that includes an HA cluster of two generic FortiGate units installed between an internal network and the Internet and running in Transparent mode.

Example Transparent mode HA network topology

The figure below shows a Transparent mode FortiGate HA cluster consisting of two FortiGate units (FGT_ha_1 and FGT_ha_2) installed between the Internet and internal network. The topology includes a router that performs NAT between the internal network and the Internet. The cluster management IP address is 10.11.101.100.

Transparent mode HA network topology



Port3 and port4 are used as the heartbeat interfaces. Because the cluster consists of two FortiGate units, you can make the connections between the heartbeat interfaces using crossover cables. You could also use switches and regular ethernet cables.

General configuration steps

This section includes web-based manager and CLI procedures. These procedures assume that the FortiGate units are running the same FortiOS firmware build and are set to the factory default configuration.

In this example, the configuration steps are identical to the NAT/Route mode configuration steps until the cluster is operating. When the cluster is operating, you can switch to Transparent mode and add basic configuration settings to cluster.

General configuration steps

1. Apply licenses to the FortiGate units to become the cluster.
2. Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. Confirm that the cluster units are operating as a cluster.

4. Switch the cluster to Transparent mode and add basic configuration settings to the cluster.
   - Switch to Transparent mode, add the management IP address and a default route.
   - Add a password for the admin administrative account.
   - View cluster status from the web-based manager or CLI.

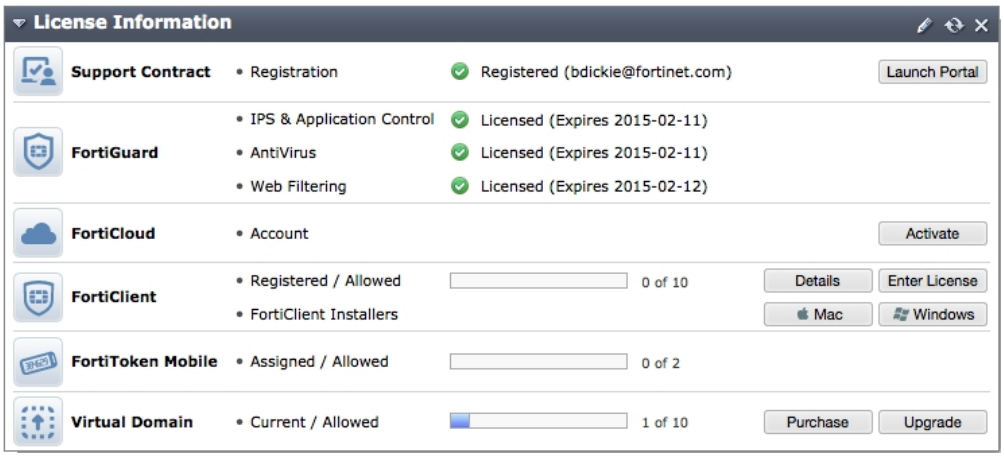
Configuring a Transparent mode active-active cluster of two FortiGate units - web-based manager

Use the following procedures to configure the FortiGate units for HA operation using the FortiGate web-based manager. These procedures assume you are starting with two FortiGate units with factory default settings.

Waiting until you have established the cluster to switch to Transparent mode means fewer configuration steps because you can switch the mode of the cluster in one step.

To configure the first FortiGate unit (host name FGT_ha_1)

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Select **OK**.
6. Go to **System > Config > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

7. Select **OK**.

   The FortiGate unit negotiates to establish an HA cluster. When you select **OK** you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

   - port1 interface virtual MAC: `00-09-0f-09-00-00`
   - port2 interface virtual MAC: `00-09-0f-09-00-01`
   - port3 interface virtual MAC: `00-09-0f-09-00-02`
   - port4 interface virtual MAC: `00-09-0f-09-00-03`

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

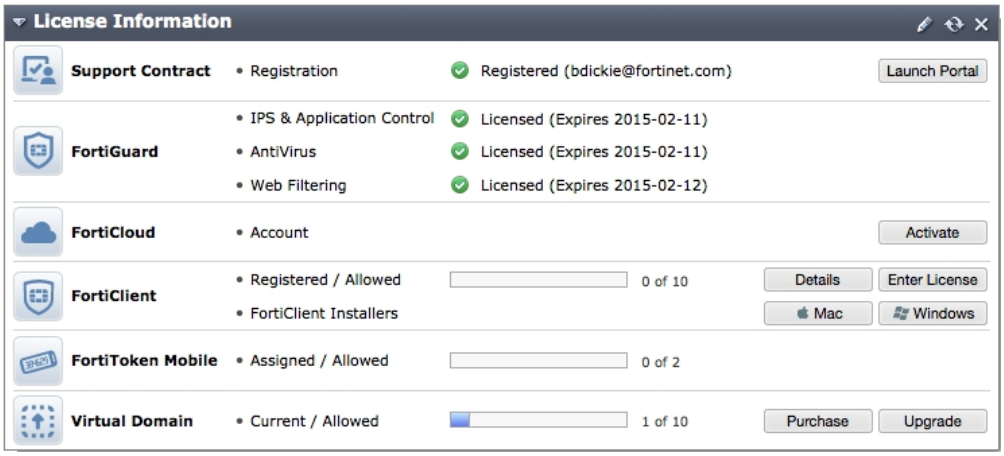
   To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

   ```
   get hardware nic port1
   .
   .
   .
   Current_HAaddr    00:09:0f:09:00:00
   Permanent_HWaddr  02:09:0f:78:18:c9
   .
   .
   .
   ```

10. Power off the first FortiGate unit.

To configure the second FortiGate unit (host name FGT_ha_2)

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
3. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_2

4. Select **OK**.
5. Go to **System > Config > HA** and change the following settings:

Mode	Active-Active
Group Name	example2.com
Password	HA_pass_2

6. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
7. Power off the second FortiGate unit.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation

occurs with no user intervention and normally takes less than a minute.

When negotiation is complete the cluster is ready to be configured for your network.

To switch the cluster to Transparent mode

Switching from NAT/Route to Transparent mode involves adding the Transparent mode management IP address and default route.

This is the minimum recommended configuration for an active-active HA cluster. You can configure other HA options at this point, but if you wait until the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

1. Start a web browser and browse to the address `https://192.168.1.99` (remember to include the “s” in `https://`).
   The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.
3. Under System Information, beside **Operation Mode** select **Change**.
4. Set Operation Mode to Transparent.
5. Configure basic Transparent mode settings.

Operation Mode	Transparent
Management IP/Mask	10.11.101.100/24
Default Gateway	10.11.101.2

6. Select **Apply**.
   The cluster switches to operating in Transparent mode. The virtual MAC addresses assigned to the cluster interfaces do not change.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

Once the cluster is operating, because configuration changes are synchronized to all cluster units, configuring the cluster is the same as configuring an individual FortiGate unit. You could have performed the following configuration steps separately on each FortiGate unit before you connected them to form a cluster.

1. Start Internet Explorer and browse to the address https://10.11.101.100 (remember to include the “s” in https://).
   The FortiGate Login is displayed.
2. Type admin in the Name field and select Login.
   The FortiGate dashboard is displayed.

The System Information dashboard widget shows the **Cluster Name** (example2.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.

3. Go to **System > Config > HA** to view the cluster members list.
   The list shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally. For example, if the list shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units, the FortiGate units are not functioning as a cluster. See Active-active HA cluster in Transparent mode on page 1331 to troubleshoot the cluster.

To add basic configuration settings to the cluster

Use the following steps to configure the cluster. Note that the following are example configuration steps only and do not represent all of the steps required to configure the cluster for a given network.

1. Log into the cluster web-based manager.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.

You added a default gateway when you switched to Transparent mode so you don't need to add a default route as part of the basic configuration of the cluster at this point.

Configuring a Transparent mode active-active cluster of two FortiGate units - CLI

Use the following procedures to configure the FortiGate units for Transparent mode HA operation using the FortiGate CLI.

To configure each FortiGate unit for HA operation

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8

Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.
   The FortiGate unit CLI login prompt appears.If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
9. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
10. Change the host name for this FortiGate unit. For example:
```
config system global
   set hostname FGT_ha_1
end
```
11. Configure HA settings.
```
config system ha
   set mode a-a
   set group-name example2.com
   set password HA_pass_2
end
```

This is the minimum recommended configuration for an active-active HA cluster. You can also configure other HA options, but if you wait until after the cluster is operating you will only have to configure these options once for the cluster instead of separately for each cluster unit.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port2 interface virtual MAC: `00-09-0f-09-00-01`
- port3 interface virtual MAC: `00-09-0f-09-00-02`
- port4 interface virtual MAC: `00-09-0f-09-00-03`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

To confirm these MAC address changes, you can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate

unit interface. For example, use the following command to view the port1 interface virtual MAC address (`MAC`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
Current_HAaddr    00:09:0f:09:00:00
Permanent_HWaddr  02:09:0f:78:18:c9
.
.
.
```

10. Display the HA configuration (optional).

```
get system ha
   group-id : 0
   group-name : example2.com
   mode : a-a
   password : *
   hbdev : "port3" 50 "port4" 50
   session-sync-dev    :
   route-ttl : 10
   route-wait : 0
   route-hold : 10
   sync-config : enable
   encryption : disable
   authentication : disable
   hb-interval : 2
   hb-lost-threshold : 20
   helo-holddown : 20
   arps : 5
   arps-interval : 8
   session-pickup : disable
   update-all-session-timer: disable
   session-sync-daemon-number: 1
   link-failed-signal : disable
   uninterruptible-upgrade: enable
   ha-mgmt-status : disable
   ha-eth-type : 8890
   hc-eth-type : 8891
   l2ep-eth-type : 8893
   ha-uptime-diff-margin: 300
   vcluster2 : disable
   vcluster-id : 1
   override : disable
   priority : 128
   slave-switch-standby: disable
   minimum-worker-threshold: 1
   monitor :
   pingserver-monitor-interface:
   pingserver-failover-threshold: 0
   pingserver-slave-force-reset: enable
   pingserver-flip-timeout: 60
   vdom : "root"
```

11. Power off the FortiGate unit.

To configure the second FortiGate unit (host name FGT_ha_2)

1. Power on the FortiGate unit.
2. Connect a null modem cable to the communications port of the management computer and to the FortiGate Console port.
3. Start HyperTerminal, enter a name for the connection, and select **OK**.
4. Configure HyperTerminal to connect directly to the communications port on the computer to which you have connected the null modem cable and select **OK**.
5. Select the following port settings and select **OK**.

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

6. Press **Enter** to connect to the FortiGate CLI.

   The FortiGate unit CLI login prompt appears.If the prompt does not appear, press Enter. If it still does not appear, power off your FortiGate unit and power it back on. If you are connected, at this stage you will see startup messages that will confirm you are connected. The login prompt will appear after the startup has completed.
7. Type `admin` and press **Enter** twice.
8. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
9. Change the host name for this FortiGate unit.

```
config system global
   set hostname FGT_ha_2
end
```

10. Configure HA settings.

```
config system ha
   set mode a-a
   set group-name example2.com
   set password HA_pass_2
end
```

    The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose network connectivity with the FortiGate unit as the HA cluster negotiates and because the FGCP changes the MAC address of the FortiGate unit interfaces.

    To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
11. Display the HA configuration (optional).

```
get system ha
   group-id : 0
   group-name : example2.com
   mode : a-a
```

```
password : *
hbdev : "port3" 50 "port4" 50
session-sync-dev    :
route-ttl : 10
route-wait : 0
route-hold : 10
sync-config : enable
encryption : disable
authentication : disable
hb-interval : 2
hb-lost-threshold : 20
helo-holddown : 20
arps : 5
arps-interval : 8
session-pickup : disable
update-all-session-timer: disable
session-sync-daemon-number: 1
link-failed-signal : disable
uninterruptible-upgrade: enable
ha-mgmt-status : disable
ha-eth-type : 8890
hc-eth-type : 8891
l2ep-eth-type : 8893
ha-uptime-diff-margin: 300
vcluster2 : disable
vcluster-id : 1
override : disable
priority : 128
schedule : round-robin
monitor :
pingserver-monitor-interface:
pingserver-failover-threshold: 0
pingserver-slave-force-reset: enable
pingserver-flip-timeout: 60
vdom : "root"
schedule : round-robin
```

12. Power off the FortiGate unit.

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
3. Connect the port3 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete the cluster is ready to be configured for your network.

To connect to the cluster CLI and switch the cluster to Transparent mode

1. Determine which cluster unit is the primary unit.
   - Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
   - Enter the command `get system status`.
   - If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step 2.
   - If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode.

2. Change to transparent mode.

```
config system settings
   set opmode transparent
   set manageip 192.168.20.3/24
   set gateway 192.168.20.1
end
```

   The cluster switches to Transparent Mode, and your administration session is disconnected.

   You can now connect to the cluster CLI using SSH to connect to the cluster internal interface using the management IP address (192.168.20.3).

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Determine which cluster unit is the primary unit.
   - Use the null-modem cable and serial connection to re-connect to the CLI of one of the cluster units.
   - Enter the command `get system status`.
   - If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit. Continue with Step "Active-active HA cluster in Transparent mode" on page 1331.
   - If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit. Connect the null-modem cable to the other cluster unit, which should be the primary unit and continue with Step 2.

If the command output includes `Current HA mode: standalone`, the cluster unit is not operating in HA mode and you should review your HA configuration.

2. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
   Model: XXXX
   Mode: a-a
   Group: 0
   Debug: 0
   ses_pickup: disable
```

```
Master:128 FGT_ha_2 FG600B3908600825 0
Slave :128 FGT_ha_1 FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard do not display information for both cluster units the FortiGate units are not functioning as a cluster. See Active-active HA cluster in Transparent mode on page 1331to troubleshoot the cluster.

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <psswrd>
end
```

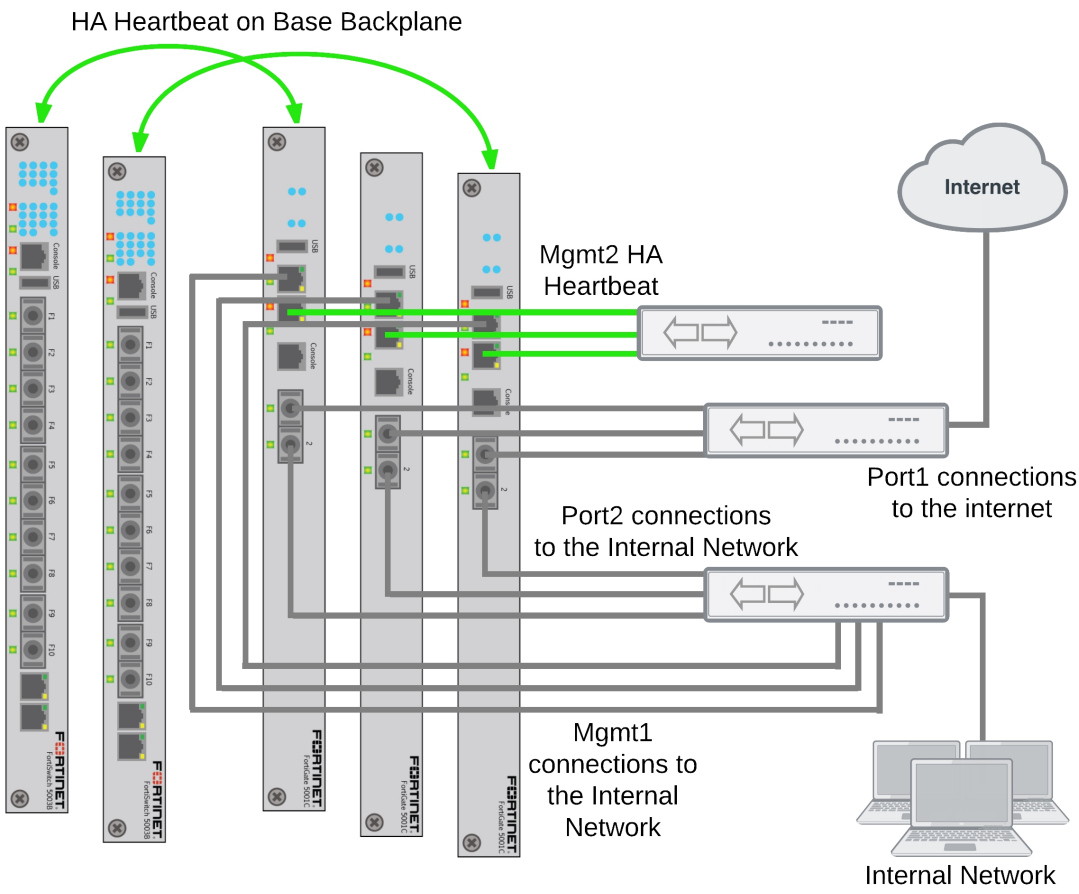
FortiGate-5000 active-active HA cluster with FortiClient licenses

This section describes how to configure an HA cluster of three FortiGate-5001C units that connect an internal network to the Internet. The FortiGate-5001C units each have a FortiClient license installed on them to support FortiClient profiles.

Normally it is recommended that you add FortiClient licenses to the FortiGate units before setting up the cluster. This example; however, describes how to apply FortiClient licenses to the FortiGate units in an operating cluster.

Example network topology

The following diagram shows an HA cluster consisting of three FortiGate-5001C cluster units (host names slot-3, slot-4, and slot-5) installed in a FortiGate-5000 series chassis with two FortiSwitch-5003B units for heartbeat communication between the cluster units. The cluster applies security features including FortiClient profiles to data traffic passing through it.



The cluster is managed from the internal network using the FortiGate-5001C mgmt1 interfaces configured as HA reserved management interfaces. Using these reserved management interfaces the overall cluster can be managed and cluster units can be managed individually. Individual management access to each cluster unit makes some operations, such as installing FortiClient licenses, easier and also allows you to view status of each cluster unit.

The reserved management interface of each cluster unit has a different IP address and retains its own MAC address. The cluster does not change the reserved management interface MAC address.

Example network topology

By default base1 and base2 are used for heartbeat communication between the FortiGate units. To use the base1 and base2 interfaces for the HA heartbeat, the example describes how to display the backplane interfaces on the web-based manager before turning on HA.

This example also includes using the mgmt2 interface for heartbeat communication for additional heartbeat redundancy.

To connect the cluster

1. Connect the FortiGate-5001C port1 interfaces to a switch and connect that switch to the Internet.
2. Connect the FortiGate-5001C port2 interfaces to a switch and connect that switch to the internal network.

3. Connect the FortiGate-5001C mgmt1 interfaces to a switch that connects to the engineering network.
4. Connect the FortiGate-5001C mgmt2 interfaces to a switch for heartbeat communication between them.

Configuring the FortiGate-5000 active-active cluster - web-based manager

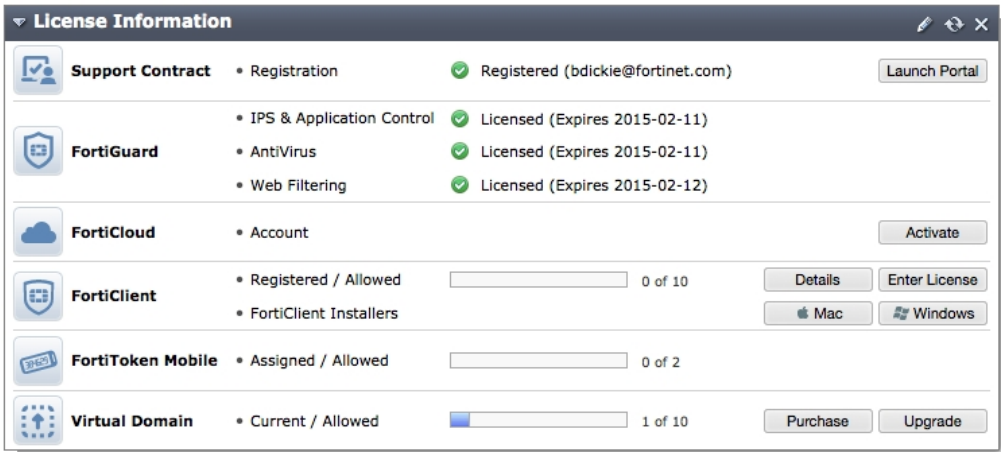
These procedures assume you are starting with three FortiGate-5001C boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001C boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5001C units

1. From the internal network, log into the web-based manager of the FortiGate-5001C unit in chassis slot 3 by connecting to the mgmt1 interface.

By default the mgmt1 interface of each FortiGate-5001C unit has the same IP address. To log into each FortiGate-5001C unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

2. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). In this example you will leave **FortiClient** licensing until after you have formed the cluster.



3. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
4. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
5. Enter a new Host Name for this FortiGate unit, for example:

New Name	5001C-Slot-3

6. Connect to the CLI and enter the following command to display backplane interfaces on the web-based manager:

```
config system global
   set show-backplane-intf enable
end
```

7. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.
   You can do this from the web-based manager by going to **System > Network > Interface**, editing each interface and setting **Administrative Status** to **Up**.

   You can also do this from the CLI using the following command:

```
config system interface
   edit base1
      set status up
   next
   edit base2
      set status up
   end
```

8. Go to **System > Network > Interface** and configure the IP address of the mgmt1 interface.
   Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001C should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

   After the FortiGate unit is operating in HA mode the mgmt1 interface will retain its original MAC address instead of being assigned a virtual MAC address.

9. Go to **System > Config > HA** and change the following settings:
   Set the **Mode** to **Active-Active**.

   Select **Reserve Management Port for Cluster Member** and select **mgmt1**.

   Set the group name and password:

Group Name	example3.com
Password	HA_pass_3

   Set the Heartbeat interface configuration to use base1, base2 and mgmt2 for heartbeat communication. Set the priority of each heartbeat interface to 50:

	Heartbeat Interface	
	Enable	**Priority**
base1	Select	50
base2	Select	50
mgmt2	Select	50

10. Select **OK**.
    The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate-5001C interfaces change to the following virtual MAC addresses:

- base1 interface virtual MAC: `00-09-0f-09-00-00`
- base2 interface virtual MAC: `00-09-0f-09-00-01`
- fabric1 interface virtual MAC: `00-09-0f-09-00-02`
- fabric2 interface virtual MAC: `00-09-0f-09-00-03`
- fabric3 interface virtual MAC: `00-09-0f-09-00-04`
- fabric4 interface virtual MAC: `00-09-0f-09-00-05`
- fabric5 interface virtual MAC: `00-09-0f-09-00-06`
- mgmt1 keeps its original MAC address
- mgmt2 interface virtual MAC: `00-09-0f-09-00-08`
- port1 interface virtual MAC: `00-09-0f-09-00-09`
- port2 interface virtual MAC: `00-09-0f-09-00-0a`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic base1
.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.
```

9. Repeat these steps for the FortiGate-5001C units in chassis slots 4 and 5, with the following differences.
   Set the mgmt1 interface IP address of each FortiGate-5001C unit to a different IP address.

   Set the FortiGate-5001C unit in chassis slot 4 host name to:

New Name	5001C-Slot-4

   Set the FortiGate-5001C unit in chassis slot 5 host name to:

New Name	5001C-Slot-5

   As you configure each FortiGate unit, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the web-based manager of one of the cluster units to view the status of the cluster. The status displays will show each unit as it is added to the cluster.

1. Log into the primary unit or any cluster unit and view the system dashboard.
   The System Information dashboard widget shows the **Cluster Name** (example3.com) and the host

names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.

2. Go to **System > Config > HA** to view the cluster members list.
   The list shows three cluster units, their host names, their roles in the cluster, and their priorities. You can check this list at any time to confirm that the cluster is operating normally.

   If the cluster members list and the dashboard do not display all of the cluster units, they are not functioning as a cluster.

To troubleshoot the cluster

See FortiGate-5000 active-active HA cluster with FortiClient licenses on page 1343.

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster web-based manager.
   You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **System > Network > Interface** and edit the **port1** interface. Set this interface IP address to the address required to connect to the interface to the Internet.
7. Edit the port2 interface and set its IP to an IP address for the internal network.

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGate units before forming the cluster. However, you can can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can log into https://support.fortinet.com and add a FortiClient license key to each licensed FortiGate unit. Then, as long as the cluster can connect to the Internet the license keys are downloaded from the FortiGuard network to all of the FortiGate units in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the web-based manager. Your cluster must be connected to the Internet.

1. Log into the -web-based manager of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside FortiClient select **Enter License**.
3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the following command to add the license key from the CLI:

```
execute FortiClient-NAC update-registration-license <license-number>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Configuring the FortiGate-5000 active-active cluster - CLI

These procedures assume you are starting with three FortiGate-5001C boards and two FortiSwitch-5003B boards installed in a compatible FortiGate-5000 series chassis. The FortiSwitch-5003B boards are in chassis slots 1 and 2 and the FortiGate-5001C boards are in chassis slots 3, 4, and 5 and the chassis is powered on. All devices are in their factory default configuration. No configuration changes to the FortiSwitch-5003B boards are required.

To configure the FortiGate-5005FA2 units

1. From the internal network, log into the CLI of the FortiGate-5001C unit in chassis slot 3 by connecting to the mgmt1 interface.

By default the mgmt1 interface of each FortiGate-5001C unit has the same IP address. To log into each FortiGate-5001C unit separately you could either disconnect the mgmt1 interfaces of the units that you don't want to log into or change the mgmt1 interface IP addresses for each unit by connecting to each unit's CLI from their console port.

   You can also use a console connection.

2. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS). In this example you will leave **FortiClient** licensing until after you have formed the cluster.
3. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
4. Change the host name for this FortiGate unit. For example:

```
config system global
  set hostname 5001C-Slot-3
end
```

5. Enter the following command to display backplane interfaces on the web-based manager:

```
config system global
   set show-backplane-intf enable
end
```

6. Set the Administrative Status of the base1 and base 2 interfaces to **Up**.

```
config system interface
   edit base1
      set status up
   next
   edit base2
      set status up
   end
```

7. Add an IP address to the mgmt1 interface.

```
config system interface
   edit mgmt1
      set ip 172.20.120.110/24
      set allowaccess http https ssl ping
   end
```

   Because mgmt1 will become the reserved management interface for the cluster unit each FortiGate-5001C should have a different mgmt1 interface IP address. Give the mgmt1 interface an address that is valid for the internal network. Once HA with the reserved Management interface is enabled the IP address of the mgmt1 interface can be on the same subnet as the port2 interface (which will also be connected to the Internal network).

8. Configure HA settings.

```
config system ha
   set mode a-a
   set ha-mgmt-status enable
   set ha-mgmt-interface mgmt1
   set group-name example3.com
   set password HA_pass_3
   set hbdev base1 50 base2 50 mgmt2 50
end
```

   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate-5001C interfaces change to the following virtual MAC addresses:

   - base1 interface virtual MAC: `00-09-0f-09-00-00`
   - base2 interface virtual MAC: `00-09-0f-09-00-01`
   - fabric1 interface virtual MAC: `00-09-0f-09-00-02`
   - fabric2 interface virtual MAC: `00-09-0f-09-00-03`
   - fabric3 interface virtual MAC: `00-09-0f-09-00-04`
   - fabric4 interface virtual MAC: `00-09-0f-09-00-05`
   - fabric5 interface virtual MAC: `00-09-0f-09-00-06`
   - mgmt1 keeps its original MAC address
   - mgmt2 interface virtual MAC: `00-09-0f-09-00-08`

- port1 interface virtual MAC: `00-09-0f-09-00-09`
- port2 interface virtual MAC: `00-09-0f-09-00-0a`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic base1
.
.
.
Current_HWaddr 00:09:0f:09:00:00
Permanent_HWaddr 00:09:0f:71:0a:dc
.
.
.
```

7. Repeat these steps for the FortiGate-5001C units in chassis slots 4 and 5, with the following differences.

   Set the mgmt1 interface IP address of each FortiGate-5001C unit to a different IP address.

   Set the FortiGate-5001C unit in chassis slot 4 host name to:

   ```
   config system global
      set hostname 5001C-Slot-4
   end
   ```

   Set the FortiGate-5001C unit in chassis slot 5 host name to:

   ```
   config system global
      set hostname 5001C-Slot-5
   end
   ```

   As you configure each FortiGate unit, they will negotiate and join the cluster.

To view cluster status

As you add units to the cluster you can log into the CLI of one of the cluster units using its reserved management interface to view the status of the cluster. The status will show each unit as it is added to the cluster.

For example, the following command output shows the status of the cluster when all three cluster units have been added:

```
get system ha status
Model: FortiGate-5001C
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
Master:128 slot-5      FG-5KC3E13800084 0
Slave :128 slot-4 FG-5KC3E13800051 1
Slave :128 slot-3 FG-5KC3E13800046 2
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG-5KC3E13800084
```

```
Slave :1 FG-5KC3E13800051
Slave :2 FG-5KC3E13800046
```

You can use this command to confirm that the cluster is operating normally. For example, if the command shows only two cluster units then one unit has left the cluster for some reason.

To troubleshoot the cluster

See FortiGate-5000 active-active HA cluster with FortiClient licenses on page 1343.

To manage each cluster unit

Because you have configured a reserved management interface, you can manage each cluster unit separately by connecting to the IP address you configured for each unit's mgmt1 interface. You can view the status of each cluster unit and make changes to each unit's configuration. For example, as described below, each cluster unit must have its own FortiClient license. You can use the reserved management IP addresses to connect to each cluster unit to install the FortiClient license for that unit.

Usually you would make configuration changes by connecting to the primary unit and changing its configuration. The cluster then synchronizes the configuration changes to all cluster units. If you connect to individual cluster units and change their configuration, those configuration changes are also synchronized to each cluster unit. The exception to this is configuration objects that are not synchronized, such as the host name, FortiClient license and so on.

You can also manage each cluster unit by logging into the primary unit CLI and using the following command to connect to other cluster units:

```
execute ha manage <cluster-index>
```

To add a password for the admin administrative account

1. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <psswrd>
end
```

To add basic configuration settings to the cluster

Use the following steps to configure the cluster.

1. Log into the cluster CLI.

   You can log into the primary unit or any one of the cluster units using the appropriate mgmt1 IP address.

2. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <psswrd>
end
```

3. Set the port1 interface IP address to the address required to connect to the interface to the Internet.

```
config system interface
   edit port1
      set ip 10.10.10.10/24
   end
```

4. Set the port2 interface IP address to the address required to connect to the interface to the internal network.

```
config system interface
  edit port2
    set ip 172.20.120.12/24
  end
```

To add a FortiClient license to each cluster unit

Normally you would add FortiClient licenses to the FortiGate units before forming the cluster. However, you can can use the following steps to add FortiClient licenses to an operating cluster.

Contact your reseller to purchase FortiClient licenses for your cluster units. Each cluster unit must have its own FortiClient license.

When you receive the license keys you can log into https://support.fortinet.com and add a FortiClient license key to each licensed FortiGate unit. Then, as long as the cluster can connect to the Internet the license keys are downloaded from the FortiGuard network to all of the FortiGate units in the cluster.

You can also use the following steps to manually add the license keys to your cluster units from the CLI. Your cluster must be connected to the Internet.

1. Log into the CLI of each cluster unit using its reserved management interface IP address.
2. Enter the following command to the unit's serial number:

```
get system status
```

3. Enter the following command to add the license key for that serial number:

```
execute FortiClient-NAC update-registration-license <license-key>
```

4. Confirm that the license has been installed and the correct number of FortiClients are licensed.

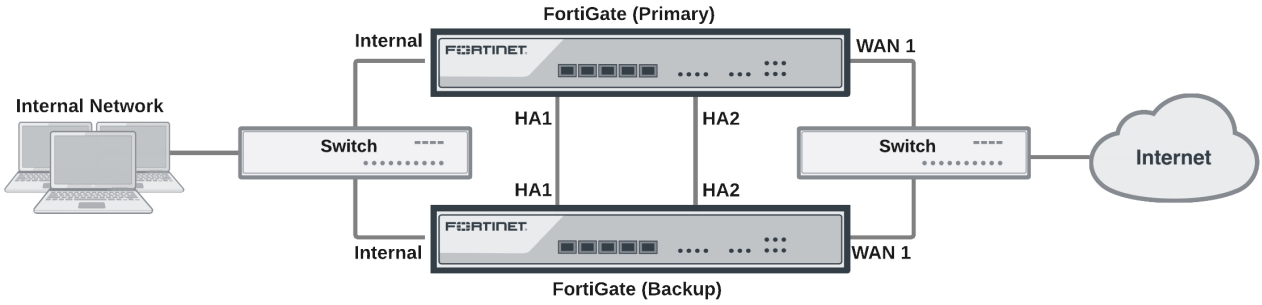
```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
     NAC: 114
WANOPT: 0
Test: 0
Other connections:
     IPsec: 0
     SSLVPN: 0
```

5. Repeat for all of the cluster units.

You can also log into the primary unit CLI and use the `execute ha manage` command to connect to each cluster unit CLI.

Converting a standalone FortiGate unit to a cluster

In this recipe, a backup FortiGate unit will be installed and connected to a FortiGate unit that has previously been installed to provide redundancy if the primary FortiGate unit fails.

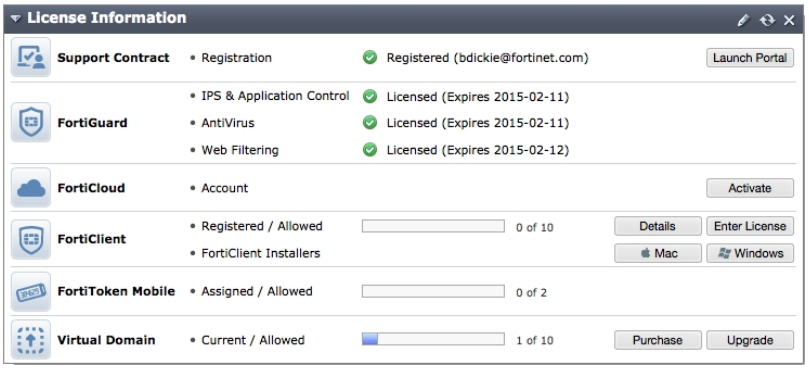


A video of this recipe is available here.

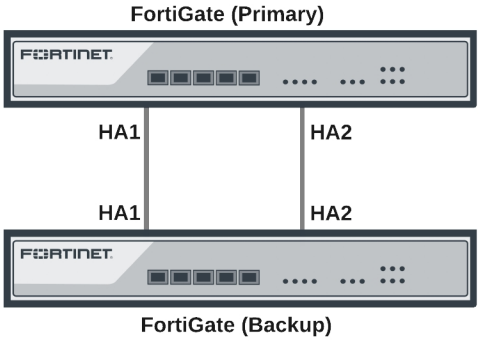
1. Adding the backup FortiGate unit and configuring HA

If the FortiGates in the cluster will be running FortiOS Carrier, apply the FortiOS Carrier license before configuring the cluster (and before applying other licenses). Applying the FortiOS Carrier license sets the configuration to factory defaults, requiring you to repeat steps performed before applying the license.

If you have not already done so, register the primary FortiGate and apply licenses to it before setting up the cluster. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMs). You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate. FortiToken licenses can be added at any time because they are synchronized to all cluster members.

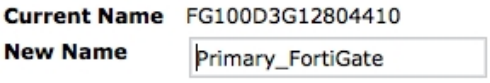


Connect your network as shown in the initial diagram, with Ethernet cables connecting the **HA** heartbeat interfaces of the two FortiGate units. If your FortiGate unit does not have dedicated HA heartbeat interfaces, you can use different interfaces, provided they are not used for any other function.



A switch must be used between the FortiGates and Internet, and another is required between the FortiGates and the internal network, as shown in the network diagram for this recipe.

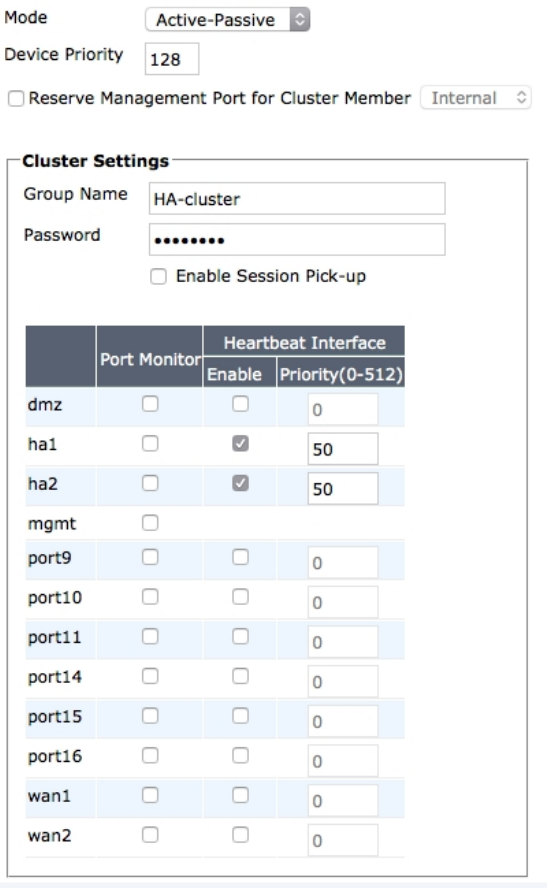
Connect to the primary FortiGate and go to **System > Dashboard > Status** and locate the **System Information** widget.



Change the unit's **Host Name** to identify it as the primary FortiGate.

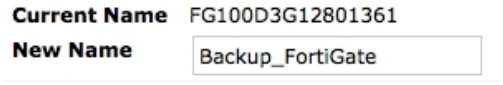
In the **System Information** widget, configure **HA Status**. Set the **Mode** to **Active-Passive** and set a **Group Name** and **Password**.

Ensure that the two **Heartbeat Interfaces** are selected and their priorities are both set to 50.



Connect to the backup FortiGate and go to **System > Dashboard > Status**.

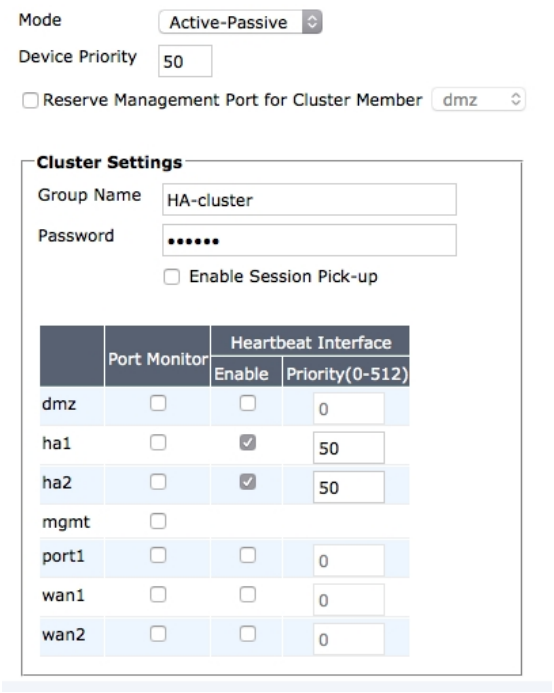
Change the unit's **Host Name** to identify it as the backup FortiGate.



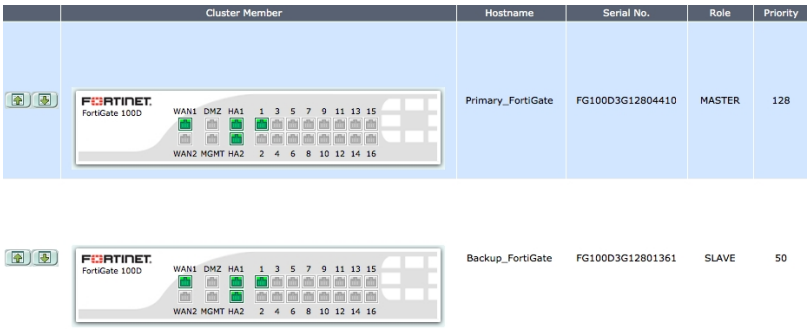
Configure **HA Status** and set the **Mode** to **Active-Passive**.

Set the **Device Priority** to be lower than the primary FortiGate. Ensure that the **Group Name** and **Password** match those on the primary FortiGate.

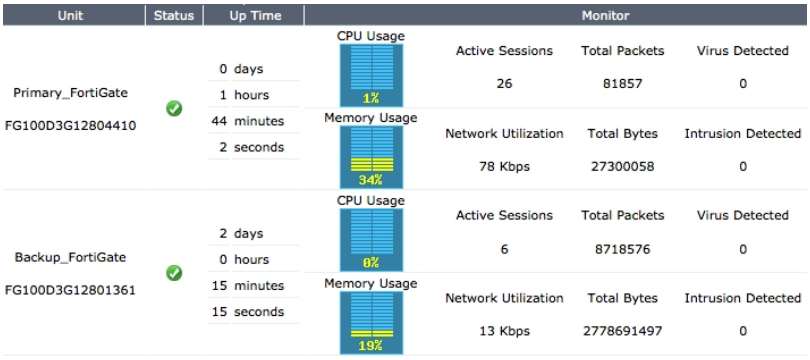
Ensure that the two **Heartbeat Interfaces** are selected and their priorities are both set to 50.



Connect to the primary FortiGate and go to **System > Config > HA** to view the cluster information.



Select **View HA Statistics** for more information on how the cluster is operating and processing traffic.



2. Results

Normally, traffic should now be flowing through the primary FortiGate. However, if the primary FortiGate is unavailable, traffic should failover and the backup FortiGate will be used. Failover will also cause the primary and backup FortiGates to reverse roles, even when both FortiGates are available again.

To test this, ping the IP address 8.8.8.8 using a PC on the internal network. After a moment, power off the primary FortiGate. You will see a momentary pause in the Ping results, until traffic diverts to the backup FortiGate, allowing the Ping traffic to continue.

```
Reply from 8.8.8.8: bytes=32 time=50ms TTL=53
Reply from 8.8.8.8: bytes=32 time=38ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Request timed out.
Reply from 8.8.8.8: bytes=32 time=482ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Reply from 8.8.8.8: bytes=32 time=36ms TTL=53
Reply from 8.8.8.8: bytes=32 time=37ms TTL=53
Reply from 8.8.8.8: bytes=32 time=38ms TTL=53
```

If you are using port monitoring, you can also unplug the primary FortiGate's Internet-facing interface to test failover.

Replacing a failed cluster unit

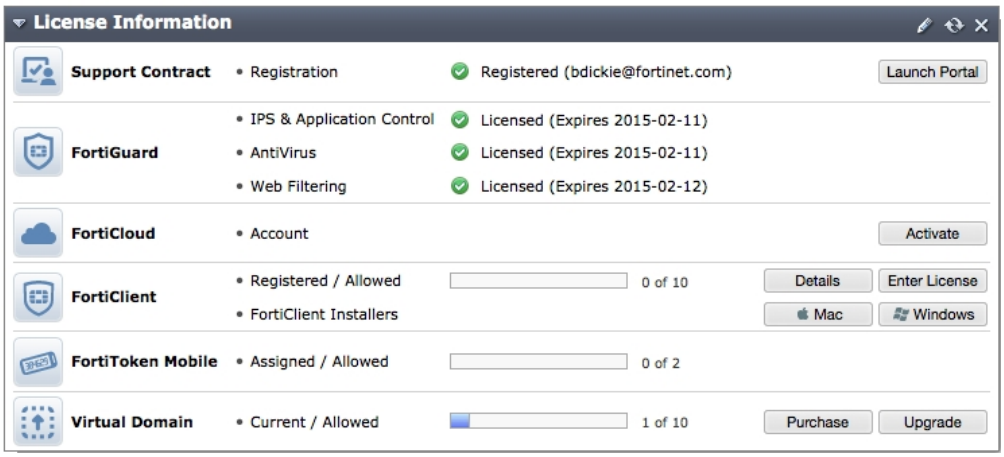
This procedure describes how to remove a failed cluster unit from a cluster and add a new one to replace it. You can also use this procedure to remove a failed unit from a cluster, repair it and add it back to the cluster. Replacing a failed does not interrupt the operation of the cluster unless you have to change how the cluster is connected to the network to accommodate the replacement unit.

You can use this procedure to replace more than one cluster unit.

To replace a failed cluster unit

1. Disconnect the failed unit from the cluster and the network.
   If you maintain other connections between the network and the still functioning cluster unit or units and between remaining cluster units network traffic will continue to be processed.
2. Repair the failed cluster unit, or obtain a replacement unit with the exact same hardware configuration as the failed cluster unit.
3. Install the same firmware build on the repaired or replacement unit as is running on the cluster.

4. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



5. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
6. Configure the repaired or replacement unit for HA operation with the same HA configuration as the cluster.
7. If the cluster is running in Transparent mode, change the operating mode of the repaired or replacement unit to Transparent mode.
8. Connect the repaired or replacement cluster unit to the cluster.
   For an example see: How to set up FGCP clustering (recommended steps) on page 1313.
9. Power on the repaired or replacement cluster unit.
   When the unit starts it negotiates to join the cluster. After it joins the cluster, the cluster synchronizes the repaired or replacement unit configuration with the configuration of the primary unit.

You can add a repaired or replacement unit to a functioning cluster at any time. The repaired or replacement cluster unit must:

- Have the same hardware configuration as the cluster units. Including the same hard disk configuration and the same AMC cards installed in the same slots.
- Have the same firmware build as the cluster.
- Be set to the same operating mode (NAT or Transparent) as the cluster.
- Be operating in single VDOM mode.

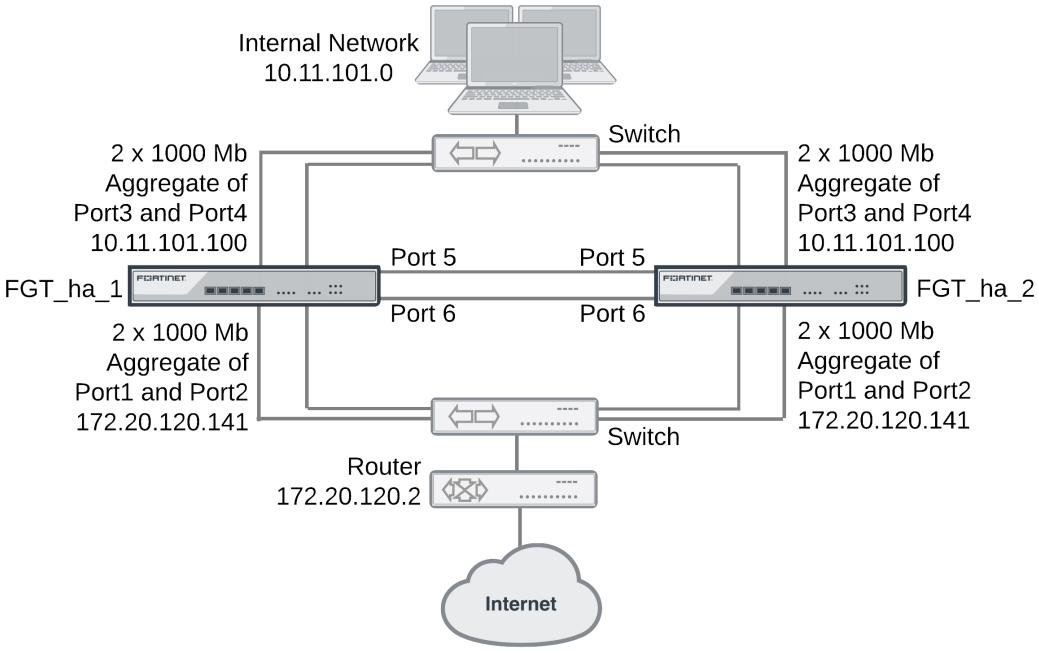
FGCP HA with 802.3ad aggregated interfaces

On FortiGate models that support it you can use 802.3ad link aggregation to combine two or more interfaces into a single aggregated interface. 802.3ad Link Aggregation and it's management protocol, Link Aggregation Control Protocol (LACP) are a method for combining multiple physical links into a single logical link.This increases both potential throughput and network resiliency. Using LACP, traffic is distributed among the physical interfaces in the link, potentially resulting in increased performance.

This example describes how to configure an HA cluster consisting of two FortiGate units with two aggregated 1000 Mb connections to the Internet using port1 and port2 and two aggregated 1000 Mb connections to the internal network using port3 and port4. The aggregated interfaces are also configured as HA monitored interfaces.

Each of the aggregate links connects to a different switch. Each switch is configured for link aggregation (2x1000Mb).

Example cluster with aggregate interfaces



HA interface monitoring, link failover, and 802.3ad aggregation

When monitoring the aggregated interface, HA interface monitoring treats the aggregated link as a single interface and does not monitor the individual physical interfaces in the link. HA interface monitoring registers the link to have failed only if all the physical interfaces in the link have failed. If only some of the physical interfaces in the link fail or become disconnected, HA considers the link to be operating normally.

HA MAC addresses and 802.3ad aggregation

If a configuration uses the Link Aggregate Control Protocol (LACP) (either passive or active), LACP is negotiated over all of the interfaces in any link. For a standalone FortiGate unit, the FortiGate LACP implementation uses the MAC address of the first interface in the link to uniquely identify that link. For example, a link consisting of port1 and port2 interfaces would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. An aggregate interface in a cluster acquires the virtual MAC address that would have been acquired by the first interface in the aggregate.

Link aggregation, HA failover performance, and HA mode

To operate an active-active or active-passive cluster with aggregated interfaces and for best performance of a cluster with aggregated interfaces, the switches used to connect the cluster unit aggregated interfaces together should support configuring multiple Link Aggregation (LAG) groups.

For example, the cluster shown above should be configured into two LAG groups on the external switch: one for the port1 and port2 aggregated interface of FGT_ha_1 and a second one for the port1 and port2 aggregate interface of FGT_ha_2. You should also be able to do the same on the internal switch for the port3 and port4 aggregated interfaces of each cluster unit.

As a result, the subordinate unit aggregated interfaces would participate in LACP negotiation while the cluster is operating. In an active-active mode cluster, packets could be redirected to the subordinate unit interfaces. As well, in active-active or active-passive mode, after a failover the subordinate unit can become a primary unit without having to perform LACP negotiation before it can process traffic. Performing LACP negotiation causes a minor failover delay.

However if you cannot configure multiple LAG groups on the switches, due to the primary and subordinate unit interfaces having the same MAC address, the switch will put all of the interfaces into the same LAG group which would disrupt the functioning of the cluster. To prevent this from happening, you must change the FortiGate aggregated interface configuration to prevent subordinate units from participating in LACP negotiation.

For example, use the following command to prevent subordinate units from participating in LACP negotiation with an aggregate interface named Port1_Port2:

```
config system interface
   edit Port1_Port2
      set lacp-ha-slave disable
   end
```

As a result of this setting, subordinate unit aggregated interfaces cannot accept packets. This means that you cannot operate the cluster in active-active mode because in active-active mode the subordinate units must be able to receive and process packets. Also, failover may take longer because after a failover the subordinate unit has to perform LACP negotiation before being able to process network traffic.

Also, it may also be necessary to configure the switch to use Passive or even Static mode for LACP to prevent the switch from sending packets to the subordinate unit interfaces, which won't be able to process them.

Finally, in some cases depending on the LACP configuration of the switches, you may experience delayed failover if the FortiGate LACP configuration is not compatible with the switch LACP configuration. For example, in some cases setting the FortiGate LACP mode to static reduces the failover delay because the FortiGate unit does not perform LACP negotiation. However there is a potential problem with this configuration because static LACP does not send periodic LAC Protocol Data Unit (LACPDU) packets to test the connections. So a non-physical failure (for example, if a device is not responding because its too busy) may not be detected and packets could be lost or delayed.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGate units to become the cluster.
2. Configure the FortiGate units for HA operation.
   - Change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the aggregated interfaces.

- Add a password for the admin administrative account.
- Add the aggregated interfaces.
- Disable `lacp-ha-slave` so that the subordinate unit does not send LACP packets.
- Add a default route.

You could also configure aggregated interfaces in each FortiGate unit before the units form a cluster.

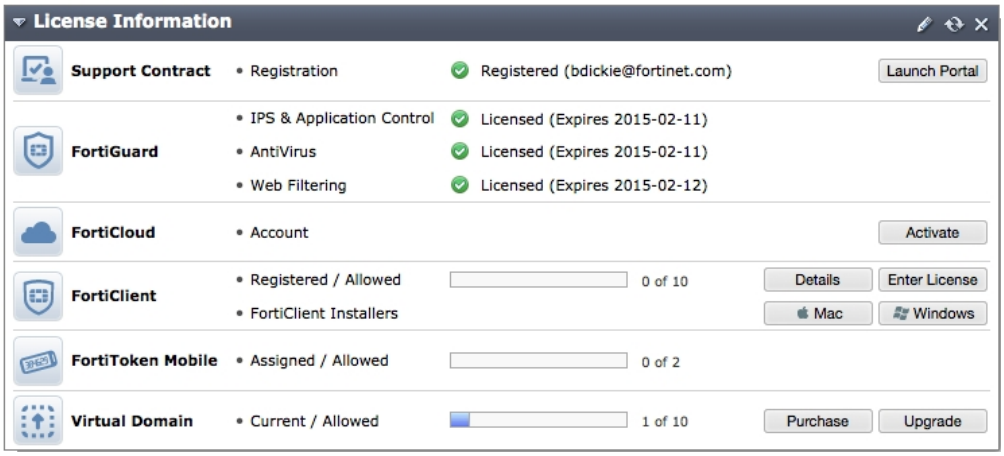
5. Configure HA port monitoring for the aggregated interfaces.

Configuring active-passive HA cluster that includes aggregated interfaces - web-based manager

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Select **OK**.
6. Go to **System > Config > HA** and change the following settings.

Mode	Active-Passive
Group Name	example5.com
Password	HA_pass_5
Heartbeat Interface	

	Enable	Priority
port5	Select	50
port6	Select	50

Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration to not use those interfaces.

7. Select **OK**.

   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

   - port1 interface virtual MAC: `00-09-0f-09-00-00`
   - port10 interface virtual MAC: `00-09-0f-09-00-01`
   - port11 interface virtual MAC: `00-09-0f-09-00-02`
   - port12 interface virtual MAC: `00-09-0f-09-00-03`
   - port13 interface virtual MAC: `00-09-0f-09-00-04`
   - port14 interface virtual MAC: `00-09-0f-09-00-05`
   - port15 interface virtual MAC: `00-09-0f-09-00-06`
   - port16 interface virtual MAC: `00-09-0f-09-00-07`
   - port17 interface virtual MAC: `00-09-0f-09-00-08`
   - port18 interface virtual MAC: `00-09-0f-09-00-09`
   - port19 interface virtual MAC: `00-09-0f-09-00-0a`
   - port2 interface virtual MAC: `00-09-0f-09-00-0b`
   - port20 interface virtual MAC: `00-09-0f-09-00-0c`
   - port3 interface virtual MAC: `00-09-0f-09-00-0d`
   - port4 interface virtual MAC: `00-09-0f-09-00-0e`
   - port5 interface virtual MAC: `00-09-0f-09-00-0f`
   - port6 interface virtual MAC: `00-09-0f-09-00-10`
   - port7 interface virtual MAC: `00-09-0f-09-00-11`
   - port8 interface virtual MAC: `00-09-0f-09-00-12`
   - port9 interface virtual MAC: `00-09-0f-09-00-13`

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

   You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

   ```
   get hardware nic port1
   .
   .
   .
   MAC: 00:09:0f:09:00:00
   ```

```
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.
   Set the second FortiGate unit host name to:

New Name	FGT_ha_2

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
   Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up a second aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
   Configure the switch so that the port3 and port4 of FGT_ha_1 make up an aggregated interface and port3 and port4 of FGT_ha_2 make up another aggregated interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
   The units negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete, the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.
   The System Information dashboard widget shows the **Cluster Name** (example5.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
2. Go to **System > Config > HA** to view the cluster members list.
   The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

See FGCP HA with 802.3ad aggregated interfaces on page 1359 to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Router > Static** > Static Routes and temporarily delete the default route.
   You cannot add an interface to a aggregated interface if any settings (such as the default route) are configured for it.
7. Go to **System > Network > Interfaces** and select **Create New** to add the aggregate interface to connect to the Internet.
8. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the Internet:

Name	Port1_Port2
Physical Interface Members	port1, port2
IP/Network Mask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New** to add the aggregate interface to connect to the internal network.
11. Set **Type** to **802.3ad Aggregate** and configure the aggregate interface to be connected to the Internet:

Name	Port3_Port4
Physical Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.
    The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:
    - port1 interface virtual MAC: `00-09-0f-09-00-00`
    - port10 interface virtual MAC: `00-09-0f-09-00-01`
    - port11 interface virtual MAC: `00-09-0f-09-00-02`
    - port12 interface virtual MAC: `00-09-0f-09-00-03`
    - port13 interface virtual MAC: `00-09-0f-09-00-04`
    - port14 interface virtual MAC: `00-09-0f-09-00-05`
    - port15 interface virtual MAC: `00-09-0f-09-00-06`
    - port16 interface virtual MAC: `00-09-0f-09-00-07`
    - port17 interface virtual MAC: `00-09-0f-09-00-08`

- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

13. Connect to the CLI and enter the following command to disable sending LACP packets from the subordinate unit:

```
config system interface
   edit Port1_Port2
      set lacp-ha-slave disable
   next
   edit Port3_Port4
      set lacp-ha-slave disable
end
```

14. Go to **Router > Static > Static Routes**.
15. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

16. Select **OK**.

To configure HA port monitoring for the aggregate interfaces

1. Go to **System > Config > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the aggregate interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes aggregate interfaces - CLI

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
2. Install any third-party certificates on the FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. Change the host name for this FortiGate unit:
   ```
   config system global
      set hostname FGT_ha_1
   end
   ```
4. Configure HA settings.
   ```
   config system ha
      set mode a-p
      set group-name example5.com
      set password HA_pass_5
      set hbdev port5 50 port6 50
   end
   ```
   Since port3 and port4 will be used for an aggregated interface, you must change the HA heartbeat configuration.

   The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

   - port1 interface virtual MAC: `00-09-0f-09-00-00`
   - port10 interface virtual MAC: `00-09-0f-09-00-01`
   - port11 interface virtual MAC: `00-09-0f-09-00-02`
   - port12 interface virtual MAC: `00-09-0f-09-00-03`
   - port13 interface virtual MAC: `00-09-0f-09-00-04`
   - port14 interface virtual MAC: `00-09-0f-09-00-05`
   - port15 interface virtual MAC: `00-09-0f-09-00-06`
   - port16 interface virtual MAC: `00-09-0f-09-00-07`
   - port17 interface virtual MAC: `00-09-0f-09-00-08`
   - port18 interface virtual MAC: `00-09-0f-09-00-09`
   - port19 interface virtual MAC: `00-09-0f-09-00-0a`
   - port2 interface virtual MAC: `00-09-0f-09-00-0b`
   - port20 interface virtual MAC: `00-09-0f-09-00-0c`
   - port3 interface virtual MAC: `00-09-0f-09-00-0d`
   - port4 interface virtual MAC: `00-09-0f-09-00-0e`
   - port5 interface virtual MAC: `00-09-0f-09-00-0f`
   - port6 interface virtual MAC: `00-09-0f-09-00-10`
   - port7 interface virtual MAC: `00-09-0f-09-00-11`
   - port8 interface virtual MAC: `00-09-0f-09-00-12`
   - port9 interface virtual MAC: `00-09-0f-09-00-13`

   To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP

table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate unit.

   Set the other FortiGate unit host name to:

```
config system global
   set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.

   Configure the switch so that the port1 and port2 of FGT_ha_1 make up an aggregated interface and port1 and port2 of FGT_ha_2 make up another aggregated interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.

   Configure the switch so that the port3 and port4 of FGT_ha_1 make up an interfaced and port3 and port4 of FGT_ha_2 make up another aggregated interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.

   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into. Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
   Model: XXXX
   Mode: a-a
   Group: 0
   Debug: 0
   ses_pickup: disable
   Master:128 FGT_ha_2 FG600B3908600825 0
   Slave :128 FGT_ha_1 FG600B3908600705 1
   number of vcluster: 1
   vcluster 1: work 169.254.0.1
   Master:0 FG600B3908600825
   Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See FGCP HA with 802.3ad aggregated interfaces on page 1359 to troubleshoot the cluster.

To add basic configuration settings and the aggregate interfaces

Use the following steps to add a few basic configuration settings and the aggregate interfaces.

1. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <psswrd>
end
```

2. Temporarily delete the default route.

   You cannot add an interface to an aggregate interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
   delete 1
end
```

3. Add the aggregate interfaces:

```
config system interface
   edit Port1_Port2
      set type aggregate
      set lacp-ha-slave disable
      set member port1 port2
```

```
      set ip 172.20.120.141/24
      set vdom root
    next
    edit Port3_Port4
      set type aggregate
      set lacp-ha-slave disable
      set member port3 port4
      set ip 10.11.101.100/24
      set vdom root
end
```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

4. Add the default route.

```
config router static
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set gateway 172.20.120.2
    set device Port1_Port2
end
```

To configure HA port monitoring for the aggregate interfaces

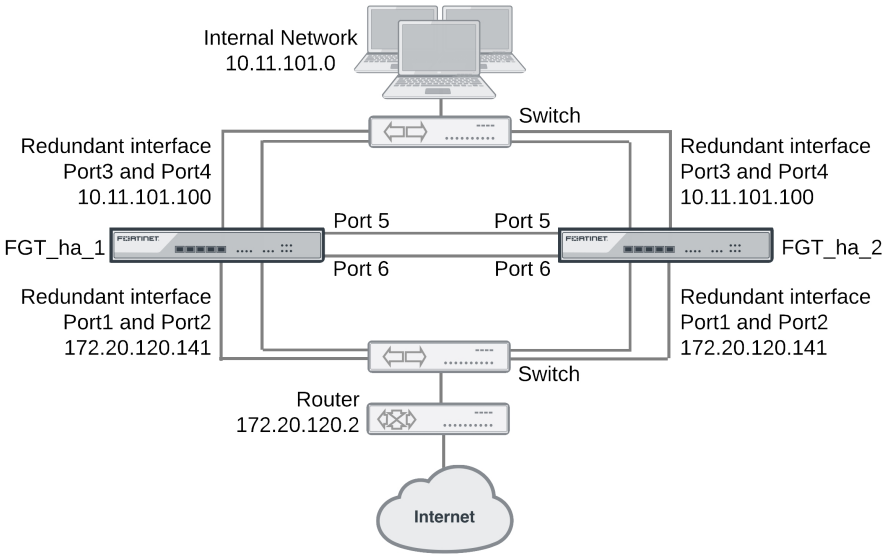
1. Configure HA port monitoring for the aggregate interfaces.

```
config system ha
  set monitor Port1_Port2 Port3_Port4
end
```

Example HA and redundant interfaces

On FortiGate models that support it you can combine two or more interfaces into a single redundant interface. A redundant interface consists of two or more physical interfaces. Traffic is processed by the first physical interface in the redundant interface. If that physical interface fails, traffic fails over to the next physical interface. Redundant interfaces don't have the benefit of improved performance that aggregate interfaces can have, but they do provide failover if a physical interface fails or is disconnected.

Example cluster with a redundant interfaces



This example describes how to configure an HA cluster consisting of two FortiGate units with a a redundant interface connection to the Internet and to an internal network. The connection to the Internet uses port1 and port2. The connection to the internal network uses port3 and port4. The HA heartbeat uses port5 and port6.

The redundant interfaces are also configured as HA monitored interfaces.

HA interface monitoring, link failover, and redundant interfaces

HA interface monitoring monitors the redundant interface as a single interface and does not monitor the individual physical interfaces in the redundant interface. HA interface monitoring registers the redundant interface to have failed only if all the physical interfaces in the redundant interface have failed. If only some of the physical interfaces in the redundant interface fail or become disconnected, HA considers the redundant interface to be operating normally.

HA MAC addresses and redundant interfaces

For a standalone FortiGate unit a redundant interface has the MAC address of the first physical interface added to the redundant interface configuration. A redundant interface consisting of port1 and port2 would have the MAC address of port1.

In an HA cluster, HA changes the MAC addresses of the cluster interfaces to virtual MAC addresses. A redundant interface in a cluster acquires the virtual MAC address that would have been acquired by the first physical interface added to the redundant interface configuration.

Connecting multiple redundant interfaces to one switch while operating in active-passive HA mode

HA assigns the same virtual MAC addresses to the subordinate unit interfaces as are assigned to the corresponding primary unit interfaces. Consider a cluster of two FortiGate units operating in active-passive mode with a redundant interface consisting of port1 and port2. You can connect multiple redundant interfaces to the same switch if you configure the switch so that it defines multiple separate redundant interfaces and puts the redundant interfaces of each cluster unit into separate redundant interfaces. In this configuration, each cluster unit forms a separate redundant interface with the switch.

However, if the switch is configured with a single four-port redundant interface configuration, because the same MAC addresses are being used by both cluster units, the switch adds all four interfaces (port1 and port2 from the primary unit and port1 and port2 from the subordinate unit) to the same redundant interface.

To avoid unpredictable results, when you connect a switch to multiple redundant interfaces in an active-passive cluster you should configure separate redundant interfaces on the switch; one for each cluster unit.

Connecting multiple redundant interfaces to one switch while operating in active-active HA mode

In an active-active cluster, all cluster units send and receive packets. To operate a cluster with redundant interfaces in active-active mode, with multiple redundant interfaces connected to the same switch, you must separate the redundant interfaces of each cluster unit into different redundant interfaces on the connecting switch.

General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGate units to become the cluster.
2. Configure the FortiGate units for HA operation.
   - Change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. View cluster status.
4. Add basic configuration settings and configure the redundant interfaces.
   - Add a password for the admin administrative account.
   - Add the redundant interfaces.
   - Add a default route.

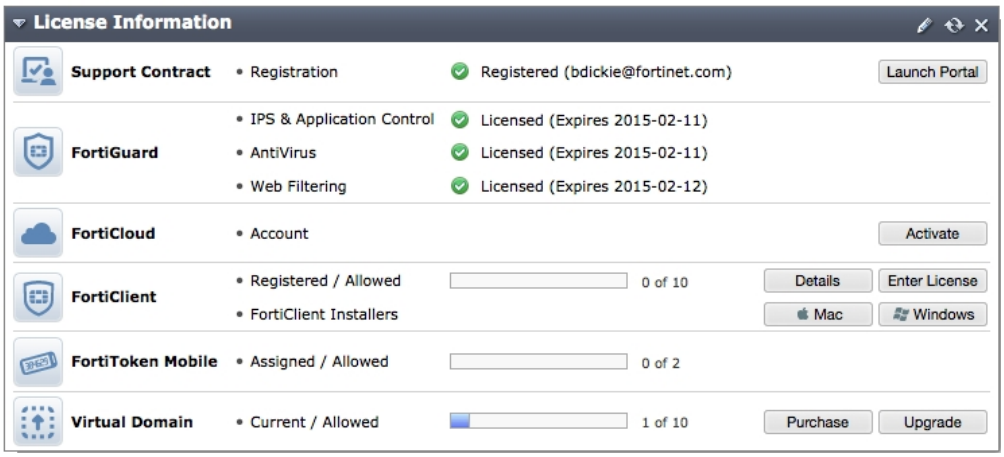
   You could also configure redundant interfaces in each FortiGate unit before they form a cluster.
5. Configure HA port monitoring for the redundant interfaces.

Configuring active-passive HA cluster that includes redundant interfaces - web-based manager

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Select **OK**.
6. Go to **System > Config > HA** and change the following settings.

Mode	Active-Passive	
Group Name	example6.com	
Password	HA_pass_6	
Heartbeat Interface		
	Enable	**Priority**
port5	Select	50
port6	Select	50

   Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

7. Select **OK**.

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.

   Set the second FortiGate unit host name to:

New Name	FGT_ha_2

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
   Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
   Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.
   The System Information dashboard widget shows the **Cluster Name** (example5.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
2. Go to **System > Config > HA** to view the cluster members list.
   The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

See Example HA and redundant interfaces on page 1371 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.
5. Select **OK**.
6. Go to **Router > Static > Static Routes** and temporarily delete the default route.

You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

7. Go to **System > Network > Interfaces** and select **Create New** to add the redundant interface to connect to the Internet.
8. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the Internet:

Name	Port1_Port2
Physical Interface Members	port1, port2
IP/Netmask	172.20.120.141/24

9. Select **OK**.
10. Select **Create New** to add the redundant interface to connect to the internal network.
11. Set **Type** to **Redundant Interface** and configure the redundant interface to be connected to the Internet:

Name	Port3_Port4
Physical Interface Members	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

12. Select **OK**.
    The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`

- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

13. Go to **Router > Static > Static Routes**.
14. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

15. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > Config > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring active-passive HA cluster that includes redundant interfaces - CLI

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. Change the host name for this FortiGate unit:

```
config system global
   set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
   set mode a-p
   set group-name example6.com
   set password HA_pass_6
   set hbdev port5 50 port6 50
end
```

Since port3 and port4 will be used for a redundant interface, you must change the HA heartbeat configuration.

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Repeat these steps for the other FortiGate unit.
   Set the other FortiGate unit host name to:

```
config system global
   set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 and port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
   Configure the switch so that the port1 and port2 of FGT_ha_1 make up a redundant interface and port1 and port2 of FGT_ha_2 make up another redundant interface.
2. Connect the port3 and port4 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
   Configure the switch so that the port3 and port4 of FGT_ha_1 make up a redundant interface and port3 and port4 of FGT_ha_2 make up another redundant interface.
3. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
4. Connect the port5 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
5. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention and normally takes less than a minute.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into.Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
   Model: XXXX
   Mode: a-a
   Group: 0
   Debug: 0
   ses_pickup: disable
   Master:128 FGT_ha_2 FG600B3908600825 0
   Slave :128 FGT_ha_1 FG600B3908600705 1
   number of vcluster: 1
   vcluster 1: work 169.254.0.1
   Master:0 FG600B3908600825
```

```
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

To troubleshoot the cluster configuration

See Example HA and redundant interfaces on page 1371 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings and the redundant interfaces.

1. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <psswrd>
end
```

2. Temporarily delete the default route.

   You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it. In this example the index of the default route is 1.

```
config router static
   delete 1
end
```

3. Add the redundant interfaces:

```
config system interface
   edit Port1_Port2
      set type redundant
      set member port1 port2
      set ip 172.20.120.141/24
      set vdom root
   next
   edit Port3_Port4
      set type redundant
      set member port3 port4
      set ip 10.11.101.100/24
      set vdom root
end
```

   The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

   - port1 interface virtual MAC: `00-09-0f-09-00-00`
   - port10 interface virtual MAC: `00-09-0f-09-00-01`
   - port11 interface virtual MAC: `00-09-0f-09-00-02`
   - port12 interface virtual MAC: `00-09-0f-09-00-03`
   - port13 interface virtual MAC: `00-09-0f-09-00-04`
   - port14 interface virtual MAC: `00-09-0f-09-00-05`
   - port15 interface virtual MAC: `00-09-0f-09-00-06`
   - port16 interface virtual MAC: `00-09-0f-09-00-07`

- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

4. Add the default route.

```
config router static
   edit 1
      set dst 0.0.0.0 0.0.0.0
      set gateway 172.20.120.2
      set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1. Configure HA port monitoring for the redundant interfaces.

```
config system ha
   set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting HA clusters

This section describes some HA clustering troubleshooting techniques.

Ignoring hardware revisions

Many FortiGate platforms have gone through multiple hardware versions and in some cases the hardware changes prevent cluster formation. If you run into this problem you can use the following command on each FortiGate to cause the cluster to ignore different hardware versions:

```
execute ha ignore-hardware-revision enable
```

This command is only available on FortiGates that have had multiple hardware revisions.

By default the command is set to prevent cluster formation between FortiGates with different hardware revisions. You can enter the following command to view its status:

```
execute ha ignore-hardware-revision status
```

Usually the incompatibility is caused by different hardware versions having different hard disks and enabling this command disables each FortiGate's hard disks. As a result of disabling hard disks the cluster will not support logging to the hard disk or WAN Optimization.

If the FortiGates do have compatible hardware versions or if you want to run a FortiGate in standalone mode you can enter the following command to disable ignoring the hardware revision and enable the hard disks:

```
execute ha ignore-hardware-revision disable
```

Affected models include but are not limited to:

- FortiGate-100D
- FortiGate-300C
- FortiGate-600C
- FortiGate-800C
- FortiGate-80C and FortiWiFi-80C
- FortiGate-60C

Its possible that a cluster will not form because the disk partition sizes of the cluster units are different. You can use the `diagnose sys ha showcsum 1 system | grep storage` command to check the disk storage checksum of each cluster unit. If the checksums are different then contact Fortinet support for help in setting up compatible storage partitions.

Before you set up a cluster

Before you set up a cluster ask yourself the following questions about the FortiGate units that you are planning to use to create a cluster.

1. Do all the FortiGate units have the same hardware configuration? Including the same hard disk configuration and the same AMC cards installed in the same slots?
2. Do all FortiGate units have the same firmware build?
3. Are all FortiGate units set to the same operating mode (NAT or Transparent)?
4. Are all the FortiGate units operating in single VDOM mode?
5. If the FortiGate units are operating in multiple VDOM mode do they all have the same VDOM configuration?

In some cases you may be able to form a cluster if different FortiGate units have different firmware builds, different VDOM configurations, and are in different operating modes. However, if you encounter problems they may be resolved by installing the same firmware build on each unit, and give them the same VDOM configuration and operating mode.

Troubleshooting the initial cluster configuration

This section describes how to check a cluster when it first starts up to make sure that it is configured and operating correctly. This section assumes you have already configured your HA cluster.

To verify that a cluster can process traffic and react to a failure

1. Add a basic security policy configuration and send network traffic through the cluster to confirm connectivity.

   For example, if the cluster is installed between the Internet and an internal network, set up a basic internal to external security policy that accepts all traffic. Then from a PC on the internal network, browse to a website on the Internet or ping a server on the Internet to confirm connectivity.
2. From your management PC, set ping to continuously ping the cluster, and then start a large download, or in some other way establish ongoing traffic through the cluster.
3. While traffic is going through the cluster, disconnect the power from one of the cluster units.

   You could also shut down or restart a cluster unit.

   Traffic should continue with minimal interruption.

4. Start up the cluster unit that you disconnected.
   The unit should re-join the cluster with little or no affect on traffic.
5. Disconnect a cable for one of the HA heartbeat interfaces.
   The cluster should keep functioning, using the other HA heartbeat interface.
6. If you have port monitoring enabled, disconnect a network cable from a monitored interface.
   Traffic should continue with minimal interruption.

To verify the cluster configuration - web-based manager

1. Log into the cluster web-based manager.
2. Check the system dashboard to verify that the System Information widget displays all of the cluster units.
3. Check the cluster member graphic to verify that the correct cluster unit interfaces are connected.
4. Go to **System > Config > HA** and verify that all of the cluster units are displayed on the cluster members list.
5. From the cluster members list, edit the primary unit (master) and verify the cluster configuration is as expected.

To troubleshoot the cluster configuration - web-based manager

1. Connect to each cluster unit web-based manager and verify that the HA configurations are the same.
2. To connect to each web-based manager, you may need to disconnect some units from the network to connect to the other if the units have the same IP address.
3. If the configurations are the same, try re-entering the cluster **Password** on each cluster unit in case you made an error typing the password when configuring one of the cluster units.
4. Check that the correct interfaces of each cluster unit are connected.
   Check the cables and interface LEDs.

   Use the Unit Operation dashboard widget, system network interface list, or cluster members list to verify that each interface that should be connected actually is connected.

   If Link is down re-verify the physical connection. Try replacing network cables or switches as required.

To verify the cluster configuration - CLI

1. Log into each cluster unit CLI.
   You can use the console connection if you need to avoid the problem of units having the same IP address.
2. Enter the command `get system status`.
   Look for the following information in the command output.

`Current HA mode: a-a, master`	The cluster units are operating as a cluster and you have connected to the primary unit.
`Current HA mode: a-a, backup`	The cluster units are operating as a cluster and you have connected to a subordinate unit.
`Current HA mode: standalone`	The cluster unit is not operating in HA mode

3. Verify that the `get system ha status` command displays all of the cluster units.
4. Enter the `get system ha` command to verify that the HA configuration is correct and the same for each cluster unit.

To troubleshoot the cluster configuration - CLI

1. Try using the following command to re-enter the cluster password on each cluster unit in case you made an error typing the password when configuring one of the cluster units.

```
config system ha
   set password <password>
end
```

2. Check that the correct interfaces of each cluster unit are connected.

   Check the cables and interface LEDs.

   Use `get hardware nic <interface_name>` command to confirm that each interface is connected. If the interface is connected the command output should contain a `Link: up` entry similar to the following:

```
get hardware nic port1
.
.
.
Link: up
.
.
.
```

   If Link is down, re-verify the physical connection. Try replacing network cables or switches as required.

More troubleshooting information

Much of the information in this HA guide can be useful for troubleshooting HA clusters. Here are some links to sections with more information.

- If sessions are lost after a failover you may need to change route-ttl to keep synchronized routes active longer. See Controlling how the FGCP synchronizes kernel routing table updates on page 1481.
- To control which cluster unit becomes the primary unit, you can change the device priority and enable override. See An introduction to the FGCP on page 1270.
- Changes made to a cluster can be lost if override is enabled. See An introduction to the FGCP on page 1270.
- In some cases, age differences among cluster units result in the wrong cluster unit becoming the primary unit. For example, if a cluster unit set to a high priority reboots, that unit will have a lower age than other cluster units. You can resolve this problem by resetting the age of one or more cluster units. See An introduction to the FGCP on page 1270. You can also adjust how sensitive the cluster is to age differences. This can be useful if large age differences cause problems. SeeAn introduction to the FGCP on page 1270 and An introduction to the FGCP on page 1270.
- If one of the cluster units needs to be serviced or removed from the cluster for other reasons, you can do so without affecting the operation of the cluster. See Disconnecting a cluster unit from a cluster on page 1451.
- The web-based manager and CLI will not allow you to configure HA if you have enabled FGSP HA. See FortiGate Session Life Support Protocol (FGSP) on page 1535.
- The web-based manager and CLI will not allow you to configure HA if one or more FortiGate unit interfaces is configured as a PPTP or L2TP client.

- The FGCP is compatible with DHCP and PPPoE but care should be taken when configuring a cluster that includes a FortiGate interface configured to get its IP address with DHCP or PPPoE. Fortinet recommends that you turn on DHCP or PPPoE addressing for an interface after the cluster has been configured. See An introduction to the FGCP on page 1270.
- Some third-party network equipment may prevent HA heartbeat communication, resulting in a failure of the cluster or the creation of a split brain scenario. For example, some switches use packets with the same Ethertype as HA heartbeat packets use for internal functions and when used for HA heartbeat communication the switch generates CRC errors and the packets are not forwarded. See Heartbeat packet Ethertypes on page 1461.
- Very busy clusters may not be able to send HA heartbeat packets quickly enough, also resulting in a split brain scenario. You may be able to resolve this problem by modifying HA heartbeat timing. See Modifying heartbeat timing on page 1462.
- Very busy clusters may suffer performance reductions if session pickup is enabled. If possible you can disable this feature to improve performance. If you require session pickup for your cluster, several options are available for improving session pickup performance. See Improving session synchronization performance on page 1496.
- If it takes longer than expected for a cluster to failover you can try changing how the primary unit sends gratuitous ARP packets. See Changing how the primary unit sends gratuitous ARP packets after a failover on page 1465.
- You can also improve failover times by configuring the cluster for subsecond failover. See Subsecond failover on page 1491 and Failover performance on page 1506.
- When you first put a FortiGate unit in HA mode you may loose connectivity to the unit. This occurs because HA changes the MAC addresses of all FortiGate unit interfaces, including the one that you are connecting to. The cluster MAC addresses also change if you change the some HA settings such as the cluster group ID. The connection will be restored in a short time as your network and PC updates to the new MAC address. To reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.
- Since HA changes all cluster unit MAC addresses, if your network uses MAC address filtering you may have to make configuration changes to account for the HA MAC addresses.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1469.
- A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID. See Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1469.
- The cluster CLI displays `slave is not in sync` messages if there is a synchronization problem between the primary unit and one or more subordinate units. See How to diagnose HA out of sync messages on page 1479.
- If you have configured dynamic routing and the new primary unit takes too long to update its routing table after a failover you can configure graceful restart and also optimize how routing updates are synchronized. See Configuring graceful restart for dynamic routing failover on page 1482 and Controlling how the FGCP synchronizes kernel routing table updates on page 1481.
- Some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur after a link failover if the switch does not detect the failure and

does not clear its MAC forwarding table. See Updating MAC forwarding tables when a link failover occurs on page 1489.

- If a link not directly connected to a cluster unit (for example, between a switch connected to a cluster interface and the network) fails you can enable remote link failover to maintain communication. See Remote link failover on page 1491.
- If you find that some cluster units are not running the same firmware build you can reinstall the correct firmware build on the cluster to upgrade all cluster units to the same firmware build. See Synchronizing the firmware build running on a new cluster unit on page 1440.

Virtual clusters

This chapter provides an introduction to virtual clustering and also contains general procedures and configuration examples that describe how to configure FortiGate HA virtual clustering.

Virtual clustering overview

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

The figure below shows an example virtual cluster configuration consisting of two FortiGate units. The virtual cluster has two virtual domains, root and Eng_vdm.

The root virtual domain includes the port1 and port2 interfaces. The Eng_vdm virtual domain includes the port5 and port6 interfaces. The port3 and port4 interfaces (not shown in the diagram) are the HA heartbeat interfaces.

FortiGate virtual clustering is limited to a cluster of 2 FortiGate units with multiple VDOMs enabled. If you want to create a cluster of more than 2 FortiGate units operating with multiple VDOMS you could consider other solutions that either do not include multiple VDOMs in one cluster or employ a feature such as standalone session synchronization. See FortiGate Session Life Support Protocol (FGSP) on page 1535.

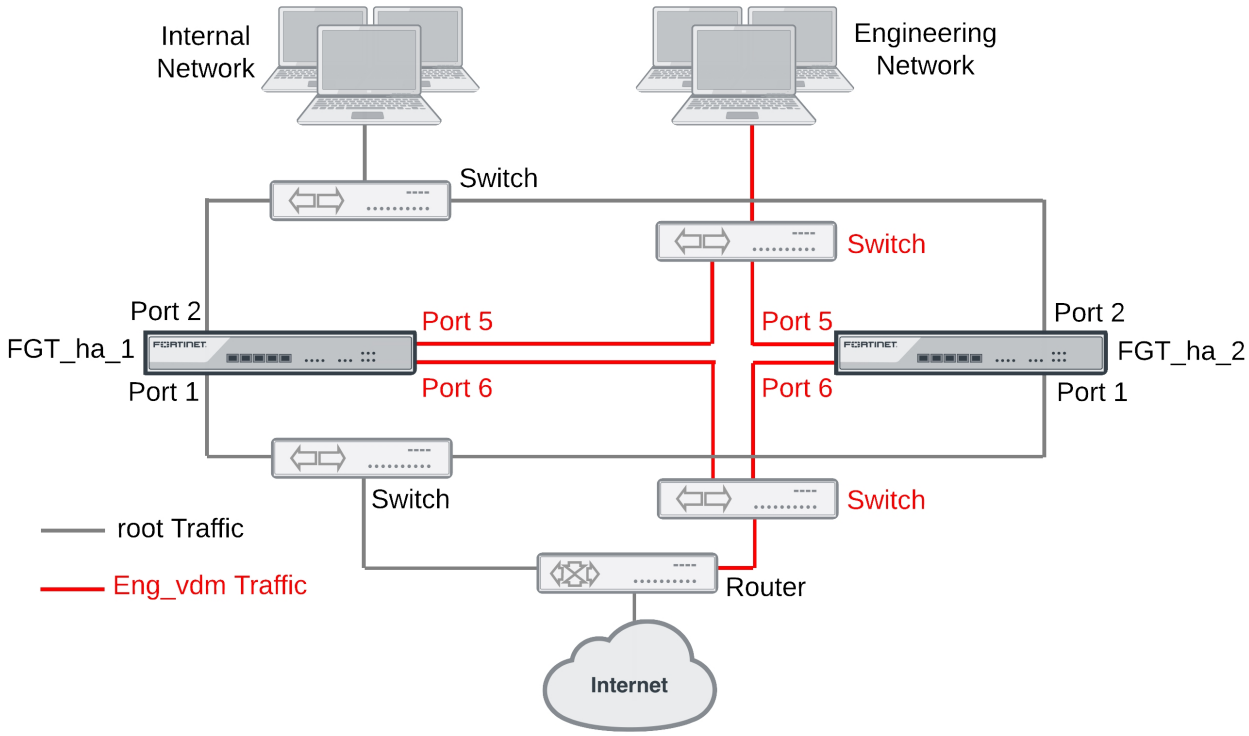
Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Example virtual cluster



Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM partionning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter `set vcluster2 enable` from the CLI `config system ha` command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

If override is enabled the cluster may renegotiate too often.You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

For more information about HA override see HA override.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all

sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved.

From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

The device priorities for virtual cluster 1 and virtual cluster 2 are not synchronized between the FortiGate units in the virtual cluster. You must configure these device priorities separately for each cluster unit.

From the CLI you configure VDOM partitioning by setting the HA mode to `a-p`. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the `config secondary-vcluster` command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit.

If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Configuring HA for virtual clustering

If your cluster uses VDOMs, you are configuring virtual clustering. Most virtual cluster HA options are the same as normal HA options. However, virtual clusters include VDOM partitioning options. Other differences between configuration options for regular HA and for virtual clustering HA are described below.

To configure HA options for a cluster with VDOMs enabled:

- Log into the global web-based manager and go to **System > Config > HA**.
- From the CLI, log into the Global Configuration:

The following example shows how to configure active-active virtual clustering:

```
config global
   config system ha
      set mode a-a
      set group-name vexample1.com
```

```
      set password vHA_pass_1
   end
end
```

The following example shows how to configure active-passive virtual clustering:

```
config global
   config system ha
      set mode a-p
      set group-name vexample1.com
      set password vHA_pass_1
   end
end
```

The following example shows how to configure VDOM partitioning for virtual clustering. In the example, the FortiGate unit is configured with three VDOMs (domain_1, domain_2, and domain_3) in addition to the root VDOM. The example shows how to set up a basic HA configuration that sets the device priority of virtual cluster 1 to 200. The example also shows how to enable `vcluster2`, how to set the device priority of virtual cluster 2 to 100 and how to add the virtual domains `domain_2` and `domain_3` to virtual cluster 2.

When you enable multiple VDOMs, `vcluster2` is enabled by default. Even so the command to enable `vcluster2` is included in this example in case for some reason it has been disabled. When `vcluster2` is enabled, `override` is also enabled.

The result of this configuration would be that the cluster unit that you are logged into becomes the primary unit for virtual cluster 1. This cluster unit processes all traffic for the root and domain_1 virtual domains.

```
config global
   config system ha
      set mode a-p
      set group-name vexample1.com
      set password vHA_pass_1
      set priority 200
      set vcluster2 enable
      config secondary-vcluster
         set vdom domain_2 domain_3
         set priority 100
      end
   end
end
```

The following example shows how to use the `execute ha manage` command to change the device priorities for virtual cluster 1 and virtual cluster 2 for the other unit in the cluster. The commands set the device priority of virtual cluster 1 to 100 and virtual cluster 2 to 200.

The result of this configuration would be that the other cluster unit becomes the primary unit for virtual cluster 2. This other cluster unit would process all traffic for the domain_2 and domain_3 virtual domains.

```
config global
   execute ha manage 1
      config system ha
         set priority 100
         set vcluster2 enable
         config secondary-vcluster
            set priority 200
         end
      end
   end
end
```

Example virtual clustering with two VDOMs and VDOM partitioning

This section describes how to configure the example virtual clustering configuration shown below. This configuration includes two virtual domains, root and Eng_vdm and includes VDOM partitioning that sends all root VDOM traffic to FGT_ha_1 and all Eng_vdom VDOM traffic to FGT_ha_2. The traffic from the internal network and the engineering network is distributed between the two FortiGate units in the virtual cluster. If one of the cluster units fails, the remaining unit will process traffic for both VDOMs.

The procedures in this example describe some of many possible sequences of steps for configuring virtual clustering. For simplicity many of these procedures assume that you are starting with new FortiGate units set to the factory default configuration. However, this is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

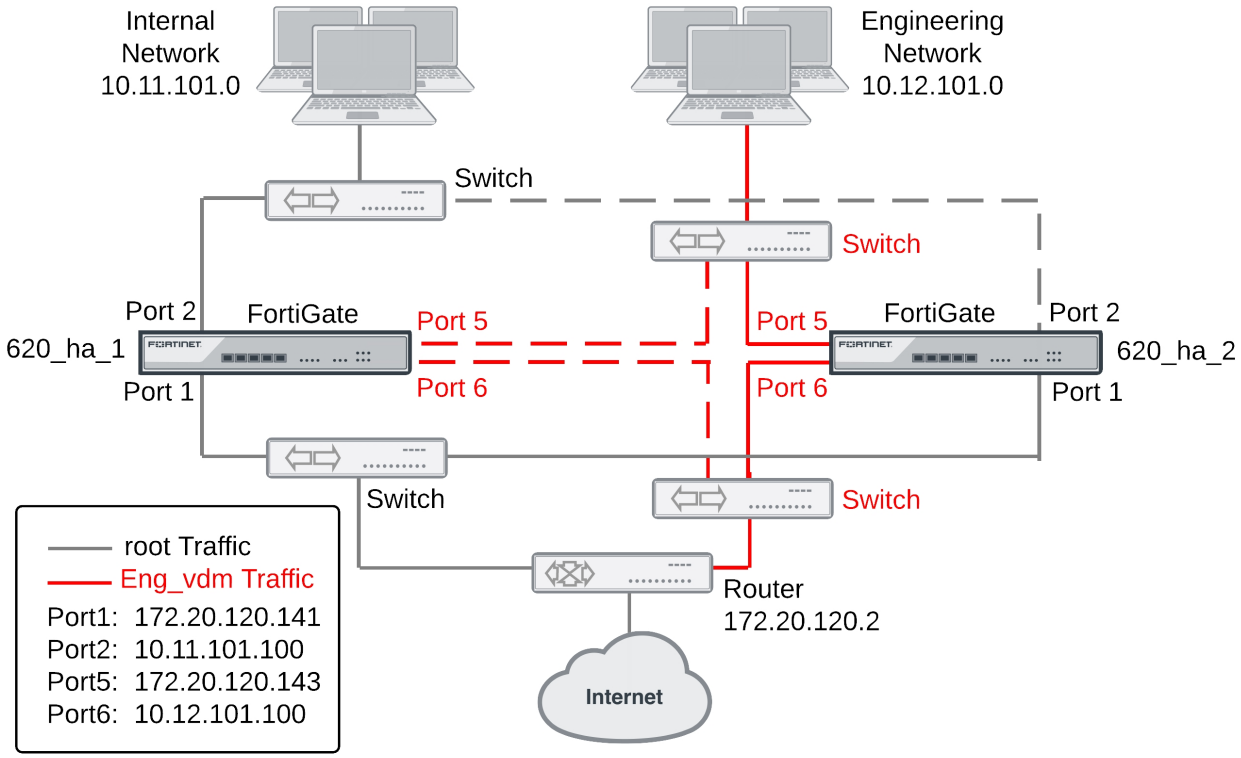
Example virtual clustering network topology

The following figure shows a typical FortiGate HA virtual cluster consisting of two FortiGate units (FGT_ha_1 and FGT_ha_2) connected to and internal network, an engineering network and the Internet. To simplify the diagram the heartbeat connections are not shown.

The traffic from the internal network is processed by the root VDOM, which includes the port1 and port2 interfaces. The traffic from the engineering network is processed by the Eng_vdm VDOM, which includes the port5 and port6 interfaces. VDOM partitioning is configured so that all traffic from the internal network is processed by FGT_ha_1 and all traffic from the engineering network is processed by FGT_ha_2.

This virtual cluster uses the default FortiGate heartbeat interfaces (port3 and port4).

Example virtual cluster showing VDOM partitioning



General configuration steps

The section includes web-based manager and CLI procedures. These procedures assume that the FortiGate units are running the same FortiOS firmware build and are set to the factory default configuration.

General configuration steps

1. Apply licenses to the FortiGate units to become the cluster.
2. Configure the FortiGate units for HA operation.
   - Optionally change each unit's host name.
   - Configure HA.
2. Connect the cluster to the network.
3. Configure VDOM settings for the cluster:
   - Enable multiple VDOMs.
   - Add the Eng_vdm VDOM.
   - Add port5 and port6 to the Eng_vdom.
4. Configure VDOM partitioning.
5. Confirm that the cluster units are operating as a virtual cluster and add basic configuration settings to the cluster.

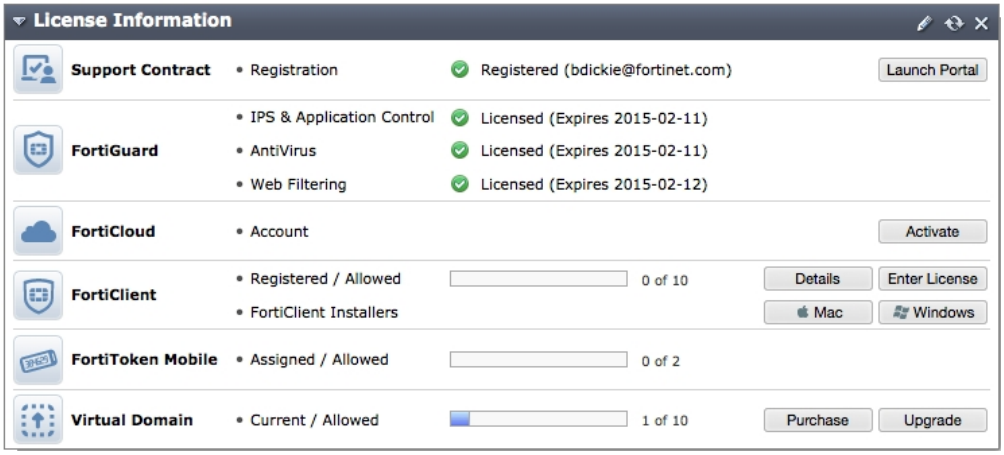
- View cluster status from the web-based manager or CLI.
- Add a password for the admin administrative account.
- Change the IP addresses and netmasks of the port1, port2, port5, and port6 interfaces.
- Add a default routes to each VDOM.

Configuring virtual clustering with two VDOMs and VDOM partitioning - web-based manager

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Select **OK**.
6. Go to **System > Config > HA** and change the following settings.

Mode	Active-Passive
Group Name	vexample2.com
Password	vHA_pass_2

7. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see Cluster virtual MAC addresses). The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

7. Power off the first FortiGate unit.
8. Repeat these steps for the second FortiGate unit.
   Set the second FortiGate unit host name to:

New Name	FGT_ha_2

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 to switch connected to the Internet.
   You could use the same switch for the port1 and port5 interfaces.
3. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
4. Connect the port6 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the engineering network.
5. Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
6. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
7. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

   When negotiation is complete you can continue.

To configure VDOM settings for the cluster

1. Log into the web-based manager.
2. On the **System Information** dashboard widget, beside **Virtual Domain** select **Enable**.
3. Select **OK** and then log back into the web-based manager.
4. Go to **System > VDOM** and select **Create New** to add a new VDOM.

Name	Eng_vdm

5. Go to **System > Network > Interfaces**.
6. Edit the **port5** interface, add it to the Eng_vdm VDOM and configure other interface settings:

Alias	Engineering_external
Virtual Domain	Eng_vdm
IP/Netmask	172.20.120.143/24

7. Select **OK**.
8. Edit the **port6** interface, add it to the Eng_vdm VDOM and configure other interface settings:

Alias	Engineering_internal
Virtual Domain	Eng_vdm
IP/Netmask	10.120.101.100/24
Administrative Access	HTTPS, PING, SSH

9. Select **OK**.

To add a default route to each VDOM

1. Go to **System > VDOM** and Enter the root VDOM.
2. Go to **Router > Static > Static Routes**.
3. Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port1
Distance	10

4. Select **Global**.
5. Go to **System > VDOM** and Enter the Eng_vdm VDOM.
6. Go to **Router > Static > Static Routes**.
7. Change the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	port5
Distance	10

To configure VDOM partitioning

1. Go to **System > Config > HA**.
   The cluster members shows two cluster units in Virtual Cluster 1.
2. Edit the cluster unit with the **Role** of **MASTER**.
3. Change **VDOM partitioning** to move the **Eng_vdm** to the **Virtual Cluster 2** list.
4. Select **OK**.
5. Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit to the following:

	Device Priority	
Host Name	**Virtual Cluster 1**	**Virtual Cluster 2**
FGT_ha_1	200	100
FGT_ha_2	100	200

You can do this by editing the HA configurations of each cluster unit in the cluster members list and changing device priorities.

Since the device priority of Virtual Cluster 1 is highest for FGT_ha_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by FGT_ha_1.

Since the device priority of Virtual Cluster 2 is highest for FGT_ha_2 and since the Eng_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng_vdm VDOM is processed by FGT_ha_2.

To view cluster status and verify the VDOM partitioning configuration

1. Log into the web-based manager.
2. Go to **System > Config > HA**.
   The cluster members list should show the following:
   - Virtual Cluster 1 contains the root VDOM.
   - FGT_ha_1 is the primary unit (master) for Virtual Cluster 1.
   - Virtual Cluster 2 contains the Eng_vdm VDOM.
   - FGT_ha_2 is the primary unit (master) for Virtual Cluster 2.

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by FGT_ha_1 and traffic for the Eng_vdm is processed by FGT_ha_2.

1. Log into the web-based manager by connecting to port2 using IP address 10.11.101.100.
   You will log into FGT_ha_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by FGT_ha_1. You can confirm that you have logged into FGT_ha_1 by checking the host name on the System Information dashboard widget.
2. Log into the web-based manager by connecting to port6 using IP address 10.12.101.100.
   You will log into FGT_ha_2 because port6 is in the Eng_vdm VDOM and all traffic for this VDOM is processed by FGT_ha_2.
3. Add security policies to the root virtual domain that allows communication from the internal network to the Internet and connect to the Internet from the internal network.
4. Log into the web-based manager and go to **Config > System > HA** and select **View HA Statistics**.
   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the FGT_ha_1 unit.
5. Add security policies to the Eng_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.
6. Log into the web-based manager and go to **Config > System > HA** and select **View HA Statistics**.
   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the FGT_ha_2 unit.

Configuring virtual clustering with two VDOMs and VDOM partitioning - CLI

These procedures assume you are starting with two FortiGate units with factory default settings.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.

FortiToken licenses can be added at any time because they are synchronized to all cluster members.

3. Change the host name for this FortiGate unit:

```
config system global
   set hostname FGT_ha_1
end
```

4. Configure HA settings.

```
config system ha
   set mode a-p
   set group-name vexample2.com
   set password vHA_pass_2
end
```

The FortiGate unit negotiates to establish an HA cluster. You may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see Cluster virtual MAC addresses). The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
```

```
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Power off the first FortiGate unit.
5. Repeat these steps for the second FortiGate unit.
   Set the other FortiGate unit host name to:

```
config system global
   set hostname FGT_ha_2
end
```

To connect the cluster to the network

1. Connect the port1 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the Internet.
2. Connect the port5 interfaces of FGT_ha_1 and FGT_ha_2 to switch connected to the Internet.
   You could use the same switch for port1 and port5.
3. Connect the port2 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the internal network.
4. Connect the port6 interfaces of FGT_ha_1 and FGT_ha_2 to a switch connected to the engineering network.
5. Connect the port3 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
6. Connect the port4 interfaces of the cluster units together. You can use a crossover Ethernet cable or regular Ethernet cables and a switch.
7. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

   When negotiation is complete you can continue.

To configure VDOM settings for the cluster

1. Log into the CLI.
2. Enter the following command to enable multiple VDOMs for the cluster.

```
config system global
   set vdom-admin enable
end
```

3. Log back into the CLI.
4. Enter the following command to add the Eng_vdm VDOM:

```
config vdom
   edit Eng_vdm
end
```

5. Edit the port5 interface, add it to the Eng_vdm VDOM and configure other interface settings:

```
config global
   config system interface
      edit port5
         set vdom Eng_vdm
```

```
        set alias Engineering_external
        set ip 172.20.12.143/24
      next
      edit port6
        set vdom Eng_vdm
        set alias Engineering_internal
        set ip 10.120.101.100/24
      end
end
```

To add a default route to each VDOM

1. Enter the following command to add default routes to the root and Eng_vdm VDOMs.

```
config vdom
  edit root
    config router static
      edit 1
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port1
      end
  next
  edit Eng_vdm
    config router static
      edit 1
        set dst 0.0.0.0/0.0.0.0
        set gateway 172.20.120.2
        set device port5
      end
end
```

To configure VDOM partitioning

1. Enter the `get system ha status` command to view cluster unit status:
   For example, from the FGT_ha_2 cluster unit CLI:

```
config global
  get system ha status
    Model: XXXX
    Mode: a-p
    Group: 0
    Debug: 0
    ses_pickup: disable
    Master:128 FGT_ha_2 FG600B3908600825 0
    Slave :128 FGT_ha_1 FG600B3908600705 1
    number of vcluster: 1
    vcluster 1: work 169.254.0.1
    Master:0 FG600B3908600825
    Slave :1 FG600B3908600705
```

   This command output shows that VDOM partitioning has not been configured because only virtual cluster 1 is shown. The command output also shows that the FGT_ha_2 is the primary unit for the cluster and for virtual cluster 1 because this cluster unit has the highest serial number

2. Enter the following commands to configure VDOM partitioning:

```
config global
  config system ha
```

```
        set vcluster2 enable
           config secondary-vcluster
              set vdom Eng_vdm
           end
     end
end
```

3. Enter the `get system ha status` command to view cluster unit status:
   For example, from the FGT_ha_2 cluster unit CLI:

```
config global
   get system ha status
      Model: XXXX
      Mode: a-p
      Group: 0
      Debug: 0
      ses_pickup: disable
      Master:128 FGT_ha_2 FG600B3908600825 0
      Slave :128 FGT_ha_1 FG600B3908600705 1
      number of vcluster: 2
      vcluster 1: work 169.254.0.1
      Master:0 FG600B3908600825
      Slave :1 FG600B3908600705
      vcluster 2: work 169.254.0.1
      Master:0 FG600B3908600825
      Slave :1 FG600B3908600705
```

   This command output shows VDOM partitioning has been configured because both virtual cluster 1 and virtual cluster 2 are visible. However the configuration is not complete because FGT_ha_2 is the primary unit for both virtual clusters. The command output shows this because under both vcluster entries the `Master` entry shows `FG600B3908600825`, which is the serial number of FGT_ha_2. As a result of this configuration, FGT_ha_2 processes traffic for both VDOMs and FGT_ha_1 does not process any traffic.

4. Change the Virtual Cluster 1 and Virtual Cluster 2 device priorities for each cluster unit so that FGT_ha_1 processes virtual cluster 1 traffic and FGT_ha_2 processes virtual cluster 2 traffic.
   Since the root VDOM is in virtual cluster 1 and the Eng_vdm VDOM is in virtual cluster 2 the result of this configuration will be that FGT_ha_1 will process all root VDOM traffic and FGT_ha_2 will process all Eng_vdm traffic. You make this happen by changing the cluster unit device priorities for each virtual cluster. You could use the following settings:

		Device Priority
Host Name	**Virtual Cluster 1**	**Virtual Cluster 2**
FGT_ha_1	200	100
FGT_ha_2	100	200

   Since the device priority is not synchronized you can edit the device priorities of each virtual cluster on each FortiGate unit separately. To do this:

   - Log into the CLI and note the FortiGate unit you have actually logged into (for example, by checking the host name displayed in the CLI prompt).
   - Change the virtual cluster 1 and 2 device priorities for this cluster unit.

- Then use the `execute ha manage` command to log into the other cluster unit CLI and set its virtual cluster 1 and 2 device priorities.

Enter the following commands from the FGT_ha_1 cluster unit CLI:

```
config global
   config system ha
      set priority 200
         config secondary-vcluster
            set priority 100
         end
   end
end
```

Enter the following commands from the FGT_ha_2 cluster unit CLI:

```
config global
   config system ha
      set priority 100
         config secondary-vcluster
            set priority 200
         end
   end
end
```

The cluster may renegotiate during this step resulting in a temporary loss of connection to the CLI and a temporary service interruption.

Since the device priority of Virtual Cluster 1 is highest for FGT_ha_1 and since the root VDOM is in Virtual Cluster 1, all traffic for the root VDOM is processed by FGT_ha_1.

Since the device priority of Virtual Cluster 2 is highest for FGT_ha_2 and since the Eng_vdm VDOM is in Virtual Cluster 2, all traffic for the Eng_vdm VDOM is processed by FGT_ha_2.

To verify the VDOM partitioning configuration

1. Log into the FGT_ha_2 cluster unit CLI and enter the following command:

```
config global
   get system ha status
      Model: XXXX
      Mode: a-p
      Group: 0
      Debug: 0
      ses_pickup: disable
      Slave :100 FGT_ha_2 FG600B3908600825 0
      Master:200 FGT_ha_1 FG600B3908600705 1
      number of vcluster: 2
      vcluster 1: standby 169.254.0.2
      Slave :1 FG600B3908600825
      Master:0 FG600B3908600705
      vcluster 2: work 169.254.0.1
      Master:0 FG600B3908600825
      Slave :1 FG600B3908600705
```

The command output shows that FGT_ha_1 is the primary unit for virtual cluster 1 (because the command output show the `Master` of virtual cluster 1 is the serial number of FGT_ha_1) and that

FGT_ha_2 is the primary unit for virtual cluster 2.

If you enter the same command from the FGT_ha_1 CLI the same information is displayed but in a different order. The command always displays the status of the cluster unit that you are logged into first.

```
config global
   get system ha status
      Model: XXXX
      Mode: a-p
      Group: 0
      Debug: 0
      ses_pickup: disable
      Master:200 FGT_ha_1 FG600B3908600705 1
      Slave :100 FGT_ha_2 FG600B3908600825 0
      number of vcluster: 2
      vcluster 1: work 169.254.0.2
      Master:0 FG600B3908600705
      Slave :1 FG600B3908600825
      vcluster 2: standby 169.254.0.1
      Slave :1 FG600B3908600705
      Master:0 FG600B3908600825
```

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for the root VDOM is processed by FGT_ha_1 and traffic for the Eng_vdm is processed by FGT_ha_2. These steps assume the cluster is operating correctly.

1. Log into the CLI by connecting to port2 using IP address 10.11.101.100.
   You will log into FGT_ha_1 because port2 is in the root VDOM and all traffic for this VDOM is processed by FGT_ha_1. You can confirm that you have logged into FGT_ha_1 by checking the host name in the CLI prompt. Also the `get system status` command displays the status of the FGT_ha_1 cluster unit.
2. Log into the web-based manager or CLI by connecting to port6 using IP address 10.12.101.100.
   You will log into FGT_ha_2 because port6 is in the Eng_vdm VDOM and all traffic for this VDOM is processed by FGT_ha_2.
3. Add security policies to the root virtual domain that allow communication from the internal network to the Internet and connect to the Internet from the internal network.
4. Log into the web-based manager and go to **Config > System > HA** and select **View HA Statistics**.
   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the FGT_ha_1 unit.
5. Add security policies to the Eng_vdm virtual domain that allow communication from the engineering network to the Internet and connect to the Internet from the engineering network.
6. Log into the web-based manager and go to **Config > System > HA** and select **View HA Statistics**.
   The statistics display shows more active sessions, total packets, network utilization, and total bytes for the FGT_ha_2 unit.

Example inter-VDOM links in a virtual clustering configuration

In a virtual domain configuration you can use inter-VDOM links to route traffic between two virtual domains operating in a single FortiGate unit without using physical interfaces. Adding an inter-VDOM link has the affect of adding two interfaces to the FortiGate unit and routing traffic between the virtual domains using the inter-VDOM link interfaces.

In a virtual clustering configuration inter-VDOM links can only be made between virtual domains that are in the same virtual cluster. So, if you are planning on configuring inter-VDOM links in a virtual clustering configuration, you should make sure the virtual domains that you want to link are in the same virtual cluster.

For example, the following tables show an example virtual clustering configuration where each virtual cluster contains four virtual domains. In this configuration you can configure inter-VDOM links between root and vdom_1 and between vdom_2 and vdom_3. But, you cannot configure inter-VDOM links between root and vdom_2 or between vdom_1 and vdom_3 (and so on).

		Hostname
Virtual Domains	**FortiGate_A**	**FortiGate_B**
root	**Priority**	**Priority**
	200	100
vdom_1	**Role**	**Role**
	Primary	Subordinate

		Hostname
Virtual Domains	**FortiGate_A**	**FortiGate_B**
vdom_2	**Priority**	**Priority**
	100	200
vdom_3	**Role**	**Role**
	Subordinate	Primary

Configuring inter-VDOM links in a virtual clustering configuration

Configuring inter-VDOM links in a virtual clustering configuration is very similar to configuring inter-VDOM links for a standalone FortiGate unit. The main difference the `config system vdom-link` command includes the `vcluster` keyword. The default setting for `vcluster` is `vcluster1`. So you only have to use the `vcluster` keyword if you are added an inter-VDOM link to virtual cluster 2.

To add an inter-VDOM link to virtual cluster 1

This procedure describes how to create an inter-VDOM link to virtual cluster 1 that results in a link between the root and vdom_1 virtual domains.

Inter-VDOM links are also called internal point-to-point interfaces.

1. Add an inter-VDOM link called `vc1link`.

```
config global
   config system vdom-link
   edit vc1link
end
```

   Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc1link0` and `vc1link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 1.

2. Bind the `vc1link0` interface to the root virtual domain and bind the `vc1link1` interface to the vdom_1 virtual domain.

```
config system interface
   edit vc1link0
        set vdom root
   next
   edit vc1link1
      set vdom vdom_1
   end
```

To add an inter-VDOM link to virtual cluster 2

This procedure describes how to create an inter-VDOM link to virtual cluster 2 that results in a link between the vdom_2 and vdom_3 virtual domains.

1. Add an inter-VDOM link called `vc2link`.

```
config global
   config system vdom-link
      edit vc2link
         set vcluster vcluster2
      end
```

   Adding the inter-VDOM link also adds two interfaces. In this example, these interfaces are called `vc2link0` and `vc2link1`. These interfaces appear in all CLI and web-based manager interface lists. These interfaces can only be added to virtual domains in virtual cluster 2.

2. Bind the `vc2link0` interface to the vdom_2 virtual domain and bind the `vc2link1` interface to the vdom_3 virtual domain.

```
config system interface
   edit vc2link0
      set vdom vdom_2
   next
   edit vc2link1
      set vdom vdom_3
   end
```

Troubleshooting virtual clustering

Troubleshooting virtual clusters is similar to troubleshooting any cluster (see FGCP configuration examples and troubleshooting on page 1313). This section describes a few testing and troubleshooting techniques for virtual clustering.

To test the VDOM partitioning configuration

You can do the following to confirm that traffic for different VDOMs will be distributed among both FortiGate units in the virtual cluster. These steps assume the cluster is otherwise operating correctly.

1. Log into the web-based manager or CLI using the IP addresses of interfaces in each VDOM.
   Confirm that you have logged into the FortiGate unit that should be processing traffic for that VDOM by checking the HTML title displayed by your web browser or the CLI prompt. Both of these should include the host name of the cluster unit that you have logged into. Also on the system Dashboard, the System Information widget displays the serial number of the FortiGate unit that you logged into. From the CLI the `get system status` command displays the status of the cluster unit that you logged into.
2. To verify that the correct cluster unit is processing traffic for a VDOM:
   - Add security policies to the VDOM that allow communication between the interfaces in the VDOM.
   - Optionally enable traffic logging and other monitoring for that VDOM and these security policies.
   - Start communication sessions that pass traffic through the VDOM.
   - Log into the web-based manager and go to **Config > System > HA** and select **View HA Statistics**. Verify that the statistics display shows more active sessions, total packets, network utilization, and total bytes for the unit that should be processing all traffic for the VDOM.
   - Optionally check traffic logging and the Top Sessions Widget for the FortiGate unit that should be processing traffic for that VDOM to verify that the traffic is being processed by this FortiGate unit.

Full mesh HA

This chapter provides an introduction to full mesh HA and also contains general procedures and configuration examples that describe how to configure FortiGate full mesh HA.

The examples in this chapter include example values only. In most cases you will substitute your own values. The examples in this chapter also do not contain detailed descriptions of configuration parameters.

Full mesh HA overview

When two or more FortiGate units are connected to a network in an HA cluster the reliability of the network is improved because the HA cluster replaces a single FortiGate unit as a single point of failure. With a cluster, a single FortiGate unit is replaced by a cluster of two or more FortiGate units.

However, even with a cluster, potential single points of failure remain. The interfaces of each cluster unit connect to a single switch and that switch provides a single connection to the network. If the switch fails or if the connection between the switch and the network fails service is interrupted to that network.

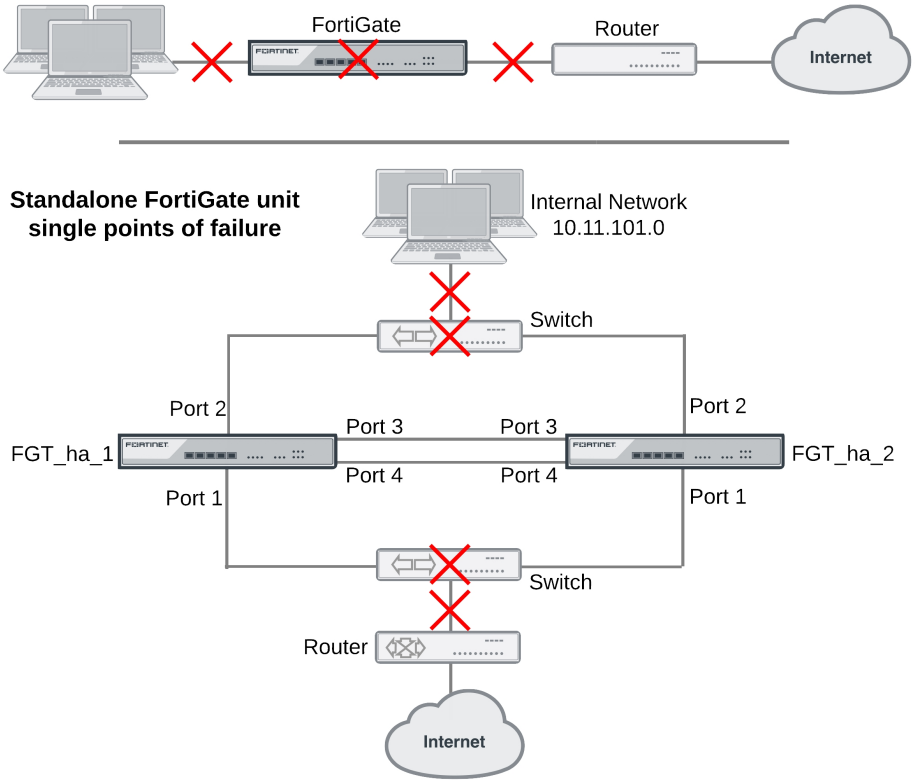
The HA cluster does improve the reliability of the network because switches are not as complex components as FortiGate units, so are less likely to fail. However, for even greater reliability, a configuration is required that includes redundant connections between the cluster the networks that it is connected to.

FortiGate models that support 802.3ad Aggregate or Redundant interfaces can be used to create a cluster configuration called full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster.

This redundant configuration can be achieved using FortiGate 802.3ad Aggregate or Redundant interfaces and a full mesh HA configuration. In a full mesh HA configuration, you connect an HA cluster consisting of two or more FortiGate units to the network using 802.3ad Aggregate or Redundant interfaces and redundant switches. Each 802.3ad Aggregate or Redundant interface is connected to two switches and both of these switches are connected to the network. In addition you must set up an IEEE 802.1Q (also called Dot1Q) or ISL link between the redundant switches connected to the Aggregate or Redundant interfaces.

The resulting full mesh configuration, an example is shown below, includes redundant connections between all network components. If any single component or any single connection fails, traffic automatically switches to the redundant component and connection and traffic flow resumes.

Single points of failure in a standalone and HA network configuration



Full mesh HA and redundant heartbeat interfaces

A full mesh HA configuration also includes redundant HA heartbeat interfaces. At least two heartbeat interfaces should be selected in the HA configuration and both sets of HA heartbeat interfaces should be connected. The HA heartbeat interfaces do not have to be configured as redundant interfaces because the FGCP handles failover between heartbeat interfaces.

Full mesh HA, redundant interfaces and 802.3ad aggregate interfaces

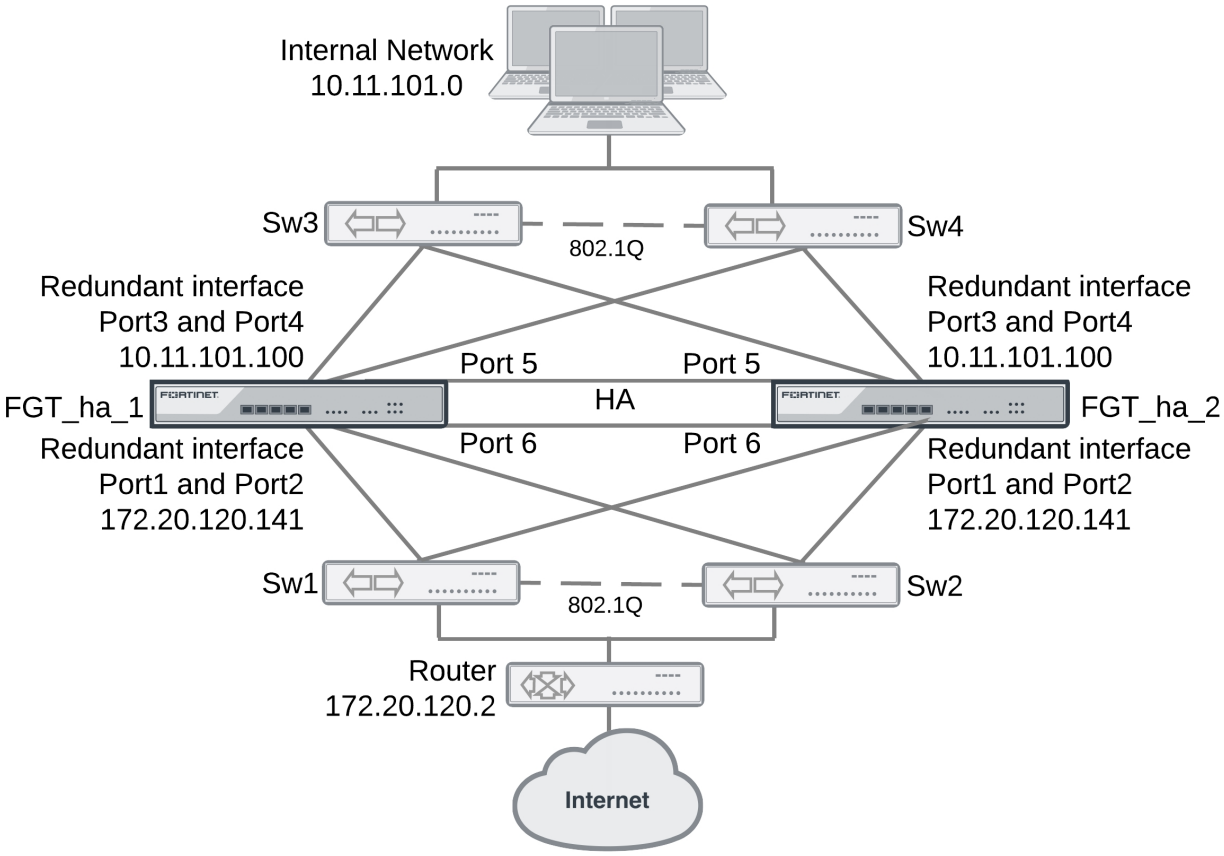
Full mesh HA is supported for both redundant interfaces and 802.3ad aggregate interfaces. In most cases you would simply use redundant interfaces. However, if your switches support 802.3ad aggregate interfaces and split multi-trunking you can use aggregate interfaces in place of redundant interfaces for full mesh HA. One advantage of using aggregate interfaces is that all of the physical interfaces in the aggregate interface can send and receive packets. As a result, using aggregate interfaces may increase the bandwidth capacity of the cluster.

Usually redundant and aggregate interfaces consist of two physical interfaces. However, you can add more than two physical interfaces to a redundant or aggregate interface. Adding more interfaces can increase redundancy protection. Adding more interfaces can also increase bandwidth capacity if you are using 802.3ad aggregate interfaces.

Example full mesh HA configuration

The following figure shows a full mesh HA configuration with a cluster of two FortiGate units. This section describes the FortiGate configuration settings and network components required for a full mesh HA configuration. This section also contains example steps for setting up this full mesh HA configuration. The procedures in this section describe one of many possible sequences of steps for configuring full mesh HA. As you become more experienced with FortiOS, HA, and full mesh HA you may choose to use a different sequence of configuration steps.

Full Mesh HA configuration



For simplicity these procedures assume that you are starting with two new FortiGate units set to the factory default configuration. However, starting from the default configuration is not a requirement for a successful HA deployment. FortiGate HA is flexible enough to support a successful configuration from many different starting points.

These procedures describe how to configure a cluster operating in NAT/Route mode because NAT/Route is the default FortiGate operating mode. However, the steps are the same if the cluster operates in Transparent mode. You can either switch the cluster units to operate in Transparent mode before beginning these procedures, or you can switch the cluster to operate in Transparent mode after HA is configured and the cluster is connected and operating.

Full mesh HA configuration

The two FortiGate units (FGT_ha_1 and FGT_ha_2) can be operating in NAT/Route or Transparent mode. Aside from the standard HA settings, the FortiGate configuration includes the following:

- The port5 and port6 interfaces configured as heartbeat interfaces. A full mesh HA configuration also includes redundant HA heartbeat interfaces.
- The port1 and port2 interfaces added to a redundant interface. Port1 is the active physical interface in this redundant interface. To make the port1 interface the active physical interface it should appear above the port2 interface in the redundant interface configuration.
- The port3 and port4 interfaces added to a redundant interface. Port3 is the active physical interface in this redundant interface. To make the port3 interface the active physical interface it should appear above the port4 interface in the redundant interface configuration.

Full mesh switch configuration

The following redundant switch configuration is required:

- Two redundant switches (Sw3 and Sw4) connected to the internal network. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.
- Two redundant switches (Sw1 and Sw2) connected to the Internet. Establish an 802.1Q (Dot1Q) or interswitch-link (ISL) connection between them.

Full mesh network connections

Make the following physical network connections for FGT_ha_1:

- Port1 to Sw1 (active)
- Port2 to Sw2 (inactive)
- Port3 to Sw3 (active)
- Port4 to Sw4 (inactive)

Make the following physical network connections for FGT_ha_2:

- Port1 to Sw2 (active)
- Port2 to Sw1 (inactive)
- Port3 to Sw4 (active)
- Port4 to Sw3 (inactive)

How packets travel from the internal network through the full mesh cluster and to the Internet

If the cluster is operating in active-passive mode and FGT_ha_2 is the primary unit, all packets take the following path from the internal network to the internet:

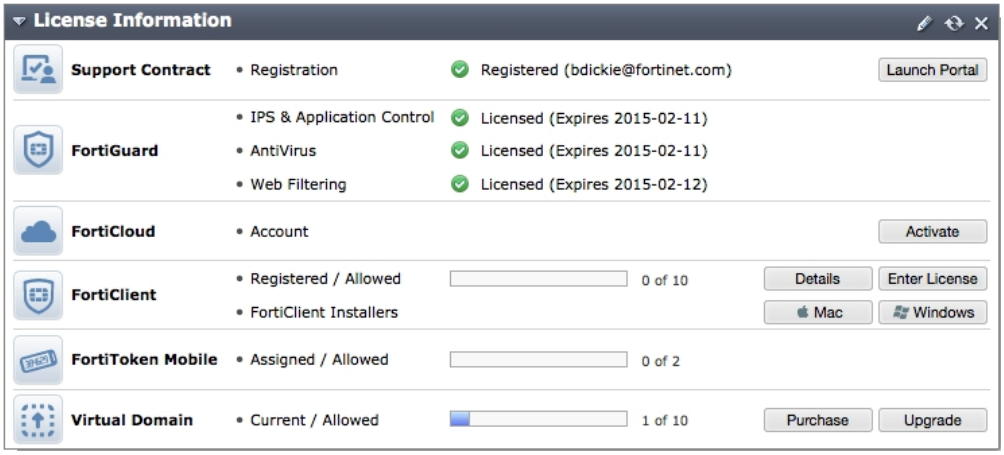
1. From the internal network to Sw4. Sw4 is the active connection to FGT_ha_2; which is the primary unit. The primary unit receives all packets.
2. From Sw4 to the FGT_ha_2 port3 interface. Active connection between Sw4 and FGT_ha_2. Port3 is the active member of the redundant interface.
3. From FGT_ha_2 port3 to FGT_ha_2 port1. Active connection between FGT_ha_2 and Sw2. Port1 is the active member of the redundant interface.
4. From Sw2 to the external router and the Internet.

Configuring full-mesh HA - web-based manager

Each cluster unit must have the same HA configuration.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation, and **FortiClient** licensing licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).



2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. On the **System Information** dashboard widget, beside **Host Name** select **Change**.
4. Enter a new Host Name for this FortiGate unit.

New Name	FGT_ha_1

5. Go to **System > Config > HA** and change the following settings.

Mode	Active-Active	
Group Name	Rexample1.com	
Password	RHA_pass_1	
Heartbeat Interface		
	Enable	**Priority**
port5	Select	50
port6	Select	50

6. Select **OK**.
   The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to

the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

6. Power off the first FortiGate unit.
7. Repeat these steps for the second FortiGate unit.
   Set the second FortiGate unit host name to:

New Name	FGT_ha_2

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
   - Port1 to Sw1 (active)
   - Port2 to Sw2 (inactive)
   - Port3 to Sw3 (active)
   - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
   - Port1 to Sw2 (active)
   - Port2 to Sw1 (inactive)
   - Port3 to Sw4 (active)
   - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.

   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view the cluster dashboard and cluster members list to confirm that the cluster units are operating as a cluster.

1. View the system dashboard.

   The System Information dashboard widget shows the **Cluster Name** (Rexample1.com) and the host names and serial numbers of the **Cluster Members**. The Unit Operation widget shows multiple cluster units.
2. Go to **System > Config > HA** to view the cluster members list.

   The list shows two cluster units, their host names, their roles in the cluster, and their priorities. You can use this list to confirm that the cluster is operating normally.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See Troubleshooting full mesh HA on page 1419 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings.

1. Log into the cluster web-based manager.
2. Go to **System > Admin > Administrators**.
3. Edit **admin** and select **Change Password**.
4. Enter and confirm a new password.

5. Select **OK**.
6. Go to **Router > Static > Static Routes** and temporarily delete the default route.
   You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.
7. Go to **System > Network > Interfaces** and select **Create New** and configure the redundant interface to connect to the Internet.

Name	Port1_Port2
Type	Redundant
Physical Interface Members	
Selected Interfaces	port1, port2
IP/Netmask	172.20.120.141/24

8. Select **OK**.
9. Select **Create New** and configure the redundant interface to connect to the internal network.

Name	Port3_Port4
Type	Redundant
Physical Interface Members	
Selected Interfaces	port3, port4
IP/Netmask	10.11.101.100/24
Administrative Access	HTTPS, PING, SSH

10. Select **OK**.
    The virtual MAC addresses of the FortiGate interfaces change to the following. Notice that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:
    - port1 interface virtual MAC: `00-09-0f-09-00-00`
    - port10 interface virtual MAC: `00-09-0f-09-00-01`
    - port11 interface virtual MAC: `00-09-0f-09-00-02`
    - port12 interface virtual MAC: `00-09-0f-09-00-03`
    - port13 interface virtual MAC: `00-09-0f-09-00-04`
    - port14 interface virtual MAC: `00-09-0f-09-00-05`
    - port15 interface virtual MAC: `00-09-0f-09-00-06`
    - port16 interface virtual MAC: `00-09-0f-09-00-07`
    - port17 interface virtual MAC: `00-09-0f-09-00-08`
    - port18 interface virtual MAC: `00-09-0f-09-00-09`
    - port19 interface virtual MAC: `00-09-0f-09-00-0a`
    - port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)

- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

11. Go to **Router > Static > Static Routes**.
12. Add the default route.

Destination IP/Mask	0.0.0.0/0.0.0.0
Gateway	172.20.120.2
Device	Port1_Port2
Distance	10

13. Select **OK**.

To configure HA port monitoring for the redundant interfaces

1. Go to **System > Config > HA**.
2. In the cluster members list, edit the primary unit.
3. Configure the following port monitoring for the redundant interfaces:

	Port Monitor
Port1_Port2	Select
Port3_Port4	Select

4. Select **OK**.

Configuring Full Mesh HA - CLI

Each cluster must have the same HA configuration. Use the following procedure to configure the FortiGate units for HA operation.

To configure the FortiGate units for HA operation

1. Register and apply licenses to the FortiGate unit. This includes **FortiCloud** activation, and **FortiClient** licensing, and entering a license key if you purchased more than 10 **Virtual Domains** (VDOMS).
2. You can also install any third-party certificates on the primary FortiGate before forming the cluster. Once the cluster is formed third-party certificates are synchronized to the backup FortiGate.
   FortiToken licenses can be added at any time because they are synchronized to all cluster members.
3. Enter a new Host Name for this FortiGate unit.

```
config system global
   set hostname FGT_ha_1
```

```
end
```

4. Configure HA settings.

```
config system ha
   set mode a-a
   set group-name Rexample1.com
   set password RHA_pass_1
   set hbdev port5 50 port6 50
end
```

The FortiGate unit negotiates to establish an HA cluster. When you select OK you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces. The MAC addresses of the FortiGate interfaces change to the following virtual MAC addresses:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-0b`
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0e`
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all arp table entries). You may be able to delete the arp table of your management PC from a command prompt using a command similar to `arp -d`.

You can use the `get hardware nic` (or `diagnose hardware deviceinfo nic`) CLI command to view the virtual MAC address of any FortiGate unit interface. For example, use the following command to view the port1 interface virtual MAC address (`Current_HWaddr`) and the port1 permanent MAC address (`Permanent_HWaddr`):

```
get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:00
```

```
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

4. Power off the first FortiGate unit.
5. Repeat these steps for the second FortiGate unit.
   Set the other FortiGate unit host name to:

```
config system global
   set hostname FGT_ha_2
end
```

To connect the cluster to your network

1. Make the following physical network connections for FGT_ha_1:
   - Port1 to Sw1 (active)
   - Port2 to Sw2 (inactive)
   - Port3 to Sw3 (active)
   - Port4 to Sw4 (inactive)
2. Make the following physical network connections for FGT_ha_2:
   - Port1 to Sw2 (active)
   - Port2 to Sw1 (inactive)
   - Port3 to Sw4 (active)
   - Port4 to Sw3 (inactive)
3. Connect Sw3 and Sw4 to the internal network.
4. Connect Sw1 and Sw2 to the external router.
5. Enable 802.1Q (Dot1Q) or ISL communication between Sw1 and Sw2 and between Sw3 and Sw4.
6. Power on the cluster units.
   The units start and negotiate to choose the primary unit and the subordinate unit. This negotiation occurs with no user intervention.

   When negotiation is complete the cluster is ready to be configured for your network.

To view cluster status

Use the following steps to view cluster status from the CLI.

1. Log into the CLI.
2. Enter `get system status` to verify the HA status of the cluster unit that you logged into.
   If the command output includes `Current HA mode: a-a, master`, the cluster units are operating as a cluster and you have connected to the primary unit.

   If the command output includes `Current HA mode: a-a, backup`, you have connected to a subordinate unit.

   If the command output includes `Current HA mode: standalone` the cluster unit is not operating in HA mode.
3. Enter the following command to confirm the HA configuration of the cluster:

```
get system ha status
```

```
Model: XXXX
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
Master:128 FGT_ha_2 FG600B3908600825 0
Slave :128 FGT_ha_1 FG600B3908600705 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG600B3908600825
Slave :1 FG600B3908600705
```

The command output shows both cluster units, their host names, their roles in the cluster, and their priorities. You can use this command to confirm that the cluster is operating normally. For example, if the command shows only one cluster unit then the other unit has left the cluster for some reason.

4. Use the `execute ha manage` command to connect to the other cluster unit's CLI and use these commands to verify cluster status.

To troubleshoot the cluster configuration

If the cluster members list and the dashboard does not display information for both cluster units the FortiGate units are not functioning as a cluster. See Troubleshooting full mesh HA on page 1419 to troubleshoot the cluster.

To add basic configuration settings and the redundant interfaces

Use the following steps to add a few basic configuration settings. Some steps use the CLI and some the web-based manager.

1. Log into the cluster CLI.
2. Add a password for the admin administrative account.

```
config system admin
   edit admin
      set password <password_str>
end
```

3. Temporarily delete the default route.

   You cannot add an interface to a redundant interface if any settings (such as the default route) are configured for it.

```
config router static
   delete 1
end
```

4. Go to **System > Network > Interface** and select **Create New** to add the redundant interface to connect to the Internet.
5. Add the redundant interface to connect to the Internet.

```
config system interface
   edit Port1_Port2
      set type redundant
      set member port1 port2
   end
```

6. Add the redundant interface to connect to the internal network.

```
config system interface
```

```
edit Port3_Port4
   set type redundant
   set member port3 port4
end
```

The virtual MAC addresses of the FortiGate interfaces change to the following. Note that port1 and port2 both have the port1 virtual MAC address and port3 and port4 both have the port3 virtual MAC address:

- port1 interface virtual MAC: `00-09-0f-09-00-00`
- port10 interface virtual MAC: `00-09-0f-09-00-01`
- port11 interface virtual MAC: `00-09-0f-09-00-02`
- port12 interface virtual MAC: `00-09-0f-09-00-03`
- port13 interface virtual MAC: `00-09-0f-09-00-04`
- port14 interface virtual MAC: `00-09-0f-09-00-05`
- port15 interface virtual MAC: `00-09-0f-09-00-06`
- port16 interface virtual MAC: `00-09-0f-09-00-07`
- port17 interface virtual MAC: `00-09-0f-09-00-08`
- port18 interface virtual MAC: `00-09-0f-09-00-09`
- port19 interface virtual MAC: `00-09-0f-09-00-0a`
- port2 interface virtual MAC: `00-09-0f-09-00-00` (same as port1)
- port20 interface virtual MAC: `00-09-0f-09-00-0c`
- port3 interface virtual MAC: `00-09-0f-09-00-0d`
- port4 interface virtual MAC: `00-09-0f-09-00-0d` (same as port3)
- port5 interface virtual MAC: `00-09-0f-09-00-0f`
- port6 interface virtual MAC: `00-09-0f-09-00-10`
- port7 interface virtual MAC: `00-09-0f-09-00-11`
- port8 interface virtual MAC: `00-09-0f-09-00-12`
- port9 interface virtual MAC: `00-09-0f-09-00-13`

7. Go to **Router > Static > Static Routes**.
8. Add the default route.

```
config router static
   edit 1
      set dst 0.0.0.0 0.0.0.0
      set gateway 172.20.120.2
      set device Port1_Port2
end
```

To configure HA port monitoring for the redundant interfaces

1. Enter the following command to configure port monitoring for the redundant interfaces:

```
config system ha
   set monitor Port1_Port2 Port3_Port4
end
```

Troubleshooting full mesh HA

Troubleshooting full mesh HA clusters is similar to troubleshooting any cluster (see FGCP configuration examples and troubleshooting on page 1313 or Troubleshooting virtual clustering on page 1406). The configuration and

operation of a full mesh HA cluster is very similar to the configuration and operation of a standard cluster. The only differences relate to the configuration, connection, and operation of the redundant interfaces and redundant switches.

- Make sure the redundant interfaces and switches are connected correctly. With so many connections it is possible to make mistakes or for cables to become disconnected.
- Confirm that the configuration of the cluster unit 802.3ad Aggregate or Redundant interfaces is correct according to the configuration procedures in this chapter.
- In some configurations with some switch hardware, MAC-learning delays on the inter-switch links on the surrounding topologies may occur. The delays occur if the gratuitous ARP packets sent by the cluster after a failover are delayed by the switches before being sent across the inter-switch link. If this happens the surrounding topologies may be delayed in recognizing the failover and will keep sending packets to the MAC address of the failed primary unit resulting in lost traffic. Resolving this problem may require changing the configuration of the switch or replacing them with switch hardware that does not delay the gratuitous ARP packets.

Operating a cluster

With some exceptions, you can operate a cluster in much the same way as you operate a standalone FortiGate unit. This chapter describes those exceptions and also the similarities involved in operating a cluster instead of a standalone FortiGate unit.

Operating a cluster

The configurations of all of the FortiGate units in a cluster are synchronized so that the cluster units can simulate a single FortiGate unit. Because of this synchronization, you manage the HA cluster instead of managing the individual cluster units. You manage the cluster by connecting to the web-based manager using any cluster interface configured for HTTPS or HTTP administrative access. You can also manage the cluster by connecting to the CLI using any cluster interface configured for SSH or telnet administrative access.

The cluster web-based manager dashboard displays the cluster name, the host name and serial number of each cluster member, and also shows the role of each unit in the cluster. The roles can be master (primary unit) and slave (subordinate units). The dashboard also displays a cluster unit front panel illustration.

You can also go to **System > Config > HA** to view the cluster members list. This includes status information for each cluster unit. You can also use the cluster members list for a number of cluster management functions including changing the HA configuration of an operating cluster, changing the host name and device priority of a subordinate unit, and disconnecting a cluster unit from a cluster. See Cluster members list on page 1437.

You can use log messages to view information about the status of the cluster. SeeClusters and logging on page 1428. You can use SNMP to manage the cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration information and receive traps.

You can configure a reserved management interface to manage individual cluster units. You can use this interface to access the web-based manager or CLI and to configure SNMP management for individual cluster units. See Managing individual cluster units using a reserved management interface on page 1422.

You can manage individual cluster units by using SSH, telnet, or the CLI console on the web-based manager dashboard to connect to the CLI of the cluster. From the CLI you can use the `execute ha manage` command to connect to the CLI of any unit in the cluster.

You can also manage individual cluster units by using a null-modem cable to connect to any cluster unit CLI. From there you can use the `execute ha manage` command to connect to the CLI of each unit in the cluster.

Operating a virtual cluster

Managing a virtual cluster is very similar to managing a cluster that does not contain multiple virtual domains. Most of the information in this chapter applies to managing both kinds of clusters. This section describes what is different when managing a virtual cluster.

If virtual domains are enabled, the cluster web-based manager dashboard displays the cluster name and the role of each cluster unit in virtual cluster 1 and virtual cluster 2.

The configuration and maintenance options that you have when you connect to a virtual cluster web-based manager or CLI depend on the virtual domain that you connect to and the administrator account that you use to connect.

If you connect to a cluster as the administrator of a virtual domain, you connect directly to the virtual domain. Since HA virtual clustering is a global configuration, virtual domain administrators cannot see HA configuration options. However, virtual domain administrators see the host name of the cluster unit that they are connecting to on the web browser title bar or CLI prompt. This host name is the host name of the primary unit for the virtual domain. Also, when viewing log messages the virtual domain administrator can select to view log messages for either of the cluster units.

If you connect to a virtual cluster as the admin administrator you connect to the global web-based manager or CLI. Even so, you are connecting to an interface and to the virtual domain that the interface has been added to. The virtual domain that you connect to does not make a difference for most configuration and maintenance operations. However, there are a few exceptions. You connect to the FortiGate unit that functions as the primary unit for the virtual domain. So the host name displayed on the web browser title bar and on the CLI is the host name of this primary unit.

Managing individual cluster units using a reserved management interface

You can provide direct management access to all cluster units by reserving a management interface as part of the HA configuration. Once this management interface is reserved, you can configure a different IP address, administrative access and other interface settings for this interface for each cluster unit. Then by connecting this interface of each cluster unit to your network you can manage each cluster unit separately from a different IP address. Configuration changes to the reserved management interface are not synchronized to other cluster units.

The reserved management interface provides direct management access to each cluster unit and gives each cluster unit a different identity on your network. This simplifies using external services, such as SNMP, to separately monitor and manage each cluster unit.

The reserved management interface is not assigned an HA virtual MAC address like other cluster interfaces. Instead the reserved management interface retains the permanent hardware address of the physical interface unless you change it using the `config system interface` command.

The reserved management interface and IP address should not be used for managing a cluster using FortiManager. To correctly manage a FortiGate HA cluster with FortiManager use the IP address of one of the cluster unit interfaces.

If you enable SNMP administrative access for the reserved management interface you can use SNMP to monitor each cluster unit using the reserved management interface IP address. To monitor each cluster unit using SNMP, just add the IP address of each cluster unit's reserved management interface to the SNMP server configuration. You must also enable direct management of cluster members in the cluster SNMP configuration.

If you enable HTTPS or HTTP administrative access for the reserved management interfaces you can connect to the web-based manager of each cluster unit. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. From the subordinate units the web-based manager has the same features as the primary unit except that unit-specific information is displayed for the subordinate unit, for example:

- The **Dashboard System Information** widget displays the subordinate unit serial number but also displays the same information about the cluster as the primary unit
- On the Cluster members list (go to **System > Config > HA**) you can change the HA configuration of the subordinate unit that you are logged into. For the primary unit and other subordinate units you can change only the host name and device priority.

- Log Access displays the logs of the subordinate that you are logged into fist, You use the HA Cluster list to view the log messages of other cluster units including the primary unit.

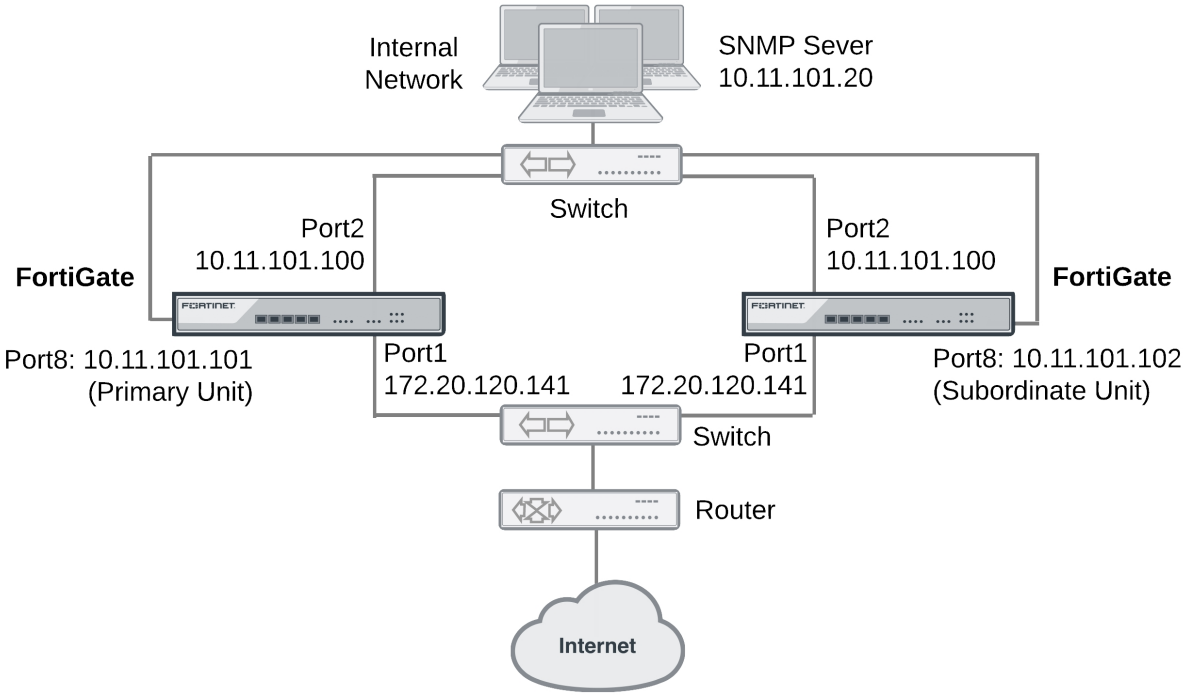
If you enable SSH or TELNET administrative access for the reserved management interfaces you can connect to the CLI of each cluster unit. The CLI prompt contains the host name of the cluster unit that you have connected to. Any configuration changes made to any of the cluster units is automatically synchronized to all cluster units. You can also use the `execute ha manage` command to connect to other cluster unit CLIs.

The reserved management interface is available in NAT/Route and in Transparent mode. It is also available if the cluster is operating with multiple VDOMs. In Transparent mode you cannot normally add an IP address to an interface. However, you can add an IP address to the reserved management interface.

Configuring the reserved management interface and SNMP remote management of individual cluster units

This example describes how to configure SNMP remote management of individual cluster units using the HA reserved management interface. The configuration consists of two FortiGate-620B units already operating as a cluster. In the example, the port8 interface of each cluster unit is connected to the internal network using the switch and configured as the reserved management interface.

SNMP remote management of individual cluster units



To configure the reserved management interface - web-based manager

1. Go to **System > Config > HA**.
2. Edit the primary unit.

3. Select **Reserve Management Port for Cluster Member** and select port8.
4. Select **OK**.

To configure the reserved management interface - CLI

From the CLI you can also configure IPv4 and IPv6 default routes that are only used by the reserved management interface.

1. Log into the CLI of any cluster unit.
2. Enter the following command to enable the reserved management interface, set port8 as the reserved interface, and add an IPv4 default route of 10.11.101.2 and an IPv6 default route of 2001:db8:0:2::20 for the reserved management interface.

```
config system ha
   set ha-mgmt-status enable
   set ha-mgmt-interface port8
   set ha-mgmt-interface-gateway 10.11.101.2
   set ha-mgmt-interface-gateway6 2001:db8:0:2::20
end
```

The reserved management interface default route is not synchronized to other cluster units.

To change the primary unit reserved management interface configuration - web-based manager

You can change the IP address of the primary unit reserved management interface from the primary unit web-based manager. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. From a PC on the internal network, browse to http://10.11.101.100 and log into the cluster web-based manager.
   This logs you into the primary unit web-based manager.

   You can identify the primary unit from its serial number or host name that appears on the System Information dashboard widget.
2. Go to **System > Network > Interfaces** and edit the port8 interface as follows:

Alias	primary_reserved
IP/Netmask	10.11.101.101/24
Administrative Access	Ping, SSH, HTTPS, SNMP

3. Select **OK**.
   You can now log into the primary unit web-based manager by browsing to https://10.11.101.101. You can also log into this primary unit CLI by using an SSH client to connect to 10.11.101.101.

To change subordinate unit reserved management interface configuration - CLI

At this point you cannot connect to the subordinate unit reserved management interface because it does not have an IP address. Instead, this procedure describes connecting to the primary unit CLI and using the `execute ha manage` command to connect to subordinate unit CLI to change the port8 interface. You can also use a serial connection to the cluster unit CLI. Configuration changes to the reserved management interface are not synchronized to other cluster units.

1. Connect to the primary unit CLI and use the `execute ha manage` command to connect to a subordinate unit CLI.

   You can identify the subordinate unit from is serial number or host name. The host name appears in the CLI prompt.

2. Enter the following command to change the port8 IP address to `10.11.101.102` and set management access to HTTPS, ping, SSH, and SNMP.

```
config system interface
   edit port8
      set ip 10.11.101.102/24
      set allowaccess https ping ssh snmp
end
```

   You can now log into the subordinate unit web-based manager by browsing to https://10.11.101.102. You can also log into this subordinate unit CLI by using an SSH client to connect to 10.11.101.102.

To configure the cluster for SNMP management using the reserved management interfaces - CLI

This procedure describes how to configure the cluster to allow the SNMP server to get status information from the primary unit and the subordinate unit. The SNMP configuration is synchronized to all cluster units. To support using the reserved management interfaces, you must add at least one HA direct management host to an SNMP community. If your SNMP configuration includes SNMP users with user names and passwords you must also enable HA direct management for SNMP users.

1. Enter the following command to add an SNMP community called `Community` and add a host to the community for the reserved management interface of each cluster unit. The host includes the IP address of the SNMP server (10.11.101.20).

```
config system snmp community
   edit 1
      set name Community
      config hosts
         edit 1
            set ha-direct enable
            set ip 10.11.101.20
         end
end
```

Enabling ha-direct in non-HA environments makes SNMP unusable.

2.

3. Enter the following command to add an SNMP user for the reserved management interface.

```
config system snmp user
   edit 1
      set ha-direct enable
      set notify-hosts 10.11.101.20
   end
```

   Configure other settings as required.

To get CPU, memory, and network usage of each cluster unit using the reserved management IP addresses

From the command line of an SNMP manager, you can use the following SNMP commands to get CPU, memory and network usage information for each cluster unit. In the examples, the community name is `Community`. The commands use the MIB field names and OIDs listed below.

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.101 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.101 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the primary unit with reserved management IP address 10.11.101.101 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.101 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the MIB fields:

```
snmpget -v2c -c Community 10.11.101.102 fgHaStatsCpuUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsMemUsage
snmpget -v2c -c Community 10.11.101.102 fgHaStatsNetUsage
```

Enter the following commands to get CPU, memory and network usage information for the subordinate unit with reserved management IP address 10.11.101.102 using the OIDs:

```
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.4.1
snmpget -v2c -c Community 10.11.101.102 1.3.6.1.4.1.12356.101.13.2.1.1.5.1
```

Managing individual cluster units in a virtual cluster

You can select the HA option **Do NOT Synchronize Management VDOM Configuration** if you have enabled multiple VDOMS and set a VDOM other than the root VDOM to be the management VDOM. You can select this option to prevent the management VDOM configuration from being synchronized between cluster units in a virtual cluster. This allows you to add an interface to the VDOM in each cluster unit and then to give the interfaces different IP addresses in each cluster unit, allowing you to manage each cluster unit separately.

You can also enable this feature using the following command:

```
config system ha
   set standalone-mgmt-vdom enable
end
```

This feature must be disabled to manage a cluster using FortiManager.

The primary unit acts as a router for subordinate unit management traffic

HA uses routing and inter-VDOM links to route subordinate unit management traffic through the primary unit to the network. Similar to a standalone FortiGate unit, subordinate units may generate their own management traffic, including:

- DNS queries.
- FortiGuard Web Filtering rating requests.
- Log messages to be sent to a FortiAnalyzer unit, to a syslog server, or to the FortiGuard Analysis and Management Service.
- Log file uploads to a FortiAnalyzer unit.
- Quarantine file uploads to a FortiAnalyzer unit.
- SNMP traps.
- Communication with remote authentication servers (RADIUS, LDAP, TACACS+ and so on)

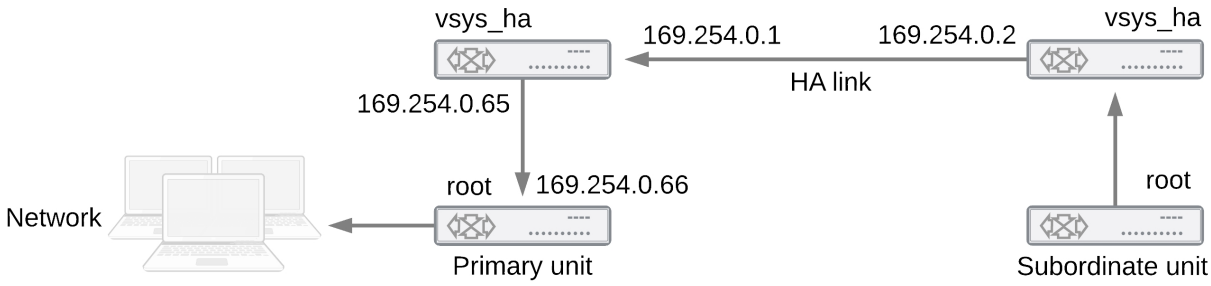
Subordinate units send this management traffic over the HA heartbeat link to the primary unit. The primary unit forwards the management traffic to its destination. The primary unit also routes replies back to the subordinate unit in the same way.

HA uses a hidden VDOM called vsys_ha for HA operations. The vsys_ha VDOM includes the HA heartbeat interfaces, and all communication over the HA heartbeat link goes through the vsys_ha VDOM. To provide communication from a subordinate unit to the network, HA adds hidden inter-VDOM links between the primary unit management VDOM and the primary unit vsys_ha VDOM. By default, root is the management VDOM.

Management traffic from the subordinate unit originates in the subordinate unit vsys_ha VDOM. The vsys_ha VDOM routes the management traffic over the HA heartbeat link to the primary unit vsys_ha VDOM. This management traffic is then routed to the primary unit management VDOM and from there out onto the network.

DNS queries and FortiGuard Web Filtering and Email Filter requests are still handled by the HA proxy so the primary unit and subordinate units share the same DNS query cache and the same FortiGuard Web Filtering and Email Filter cache. In a virtual clustering configuration, the cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering, Email Filtering, and DNS query cache.

Subordinate unit management traffic path



Cluster communication with RADIUS and LDAP servers

In an active-passive cluster, only the primary unit processes traffic, so the primary unit communicates with RADIUS or LDAP servers. In a cluster that is operating in active-active mode, subordinate units send RADIUS and LDAP requests to the primary unit over the HA heartbeat link and the primary units routes them to their destination. The primary unit relays the responses back to the subordinate unit.

Clusters and FortiGuard services

This section describes how various FortiGate HA clustering configurations communicate with the FDN.

In an operating cluster, the primary unit communicates directly with the FortiGuard Distribution Network (FDN). Subordinate units also communicate directly with the FDN but as described above, all communication between subordinate units and the FDN is routed through the primary unit.

You must register and license all of the units in a cluster for all required FortiGuard services, both because all cluster units communicate with the FDN and because any cluster unit could potentially become the primary unit.

FortiGuard and active-passive clusters

For an active-passive cluster, only the primary unit processes traffic. Even so, all cluster units communicate with the FDN. Only the primary unit sends FortiGuard Web Filtering and Antispam requests to the FDN. All cluster units receive FortiGuard Antivirus, IPS, and application control updates from the FDN.

In an active-passive cluster the FortiGuard Web Filter and Email Filter caches are located on the primary unit in the same way as for a standalone FortiGate unit. The caches are not shared among cluster units so after a failover the new primary unit must build up new caches.

In an active-passive cluster all cluster units also communicate with the FortiGuard Analysis and Management Service (FAMS).

FortiGuard and active-active clusters

For an active-active cluster, both the primary unit and the subordinate units process traffic. Communication between the cluster units and the FDN is the same as for active-passive clusters with the following exception.

Because the subordinate units process traffic, they may also be making FortiGuard Web Filtering and Email Filter requests. The primary unit receives all such requests from the subordinate units and relays them to the FDN and then relays the FDN responses back to the subordinate units. The FortiGuard Web Filtering and Email Filtering URL caches are maintained on the primary unit. The primary unit caches are used for primary and subordinate unit requests.

FortiGuard and virtual clustering

For a virtual clustering configuration the management virtual domain of each cluster unit communicates with the FDN. The cluster unit that is the primary unit for the management virtual domain maintains the FortiGuard Web Filtering and Email Filtering caches. All FortiGuard Web Filtering and Email Filtering requests are proxied by the management VDOM of the cluster unit that is the primary unit for the management virtual domain.

Clusters and logging

This section describes the log messages that provide information about how HA is functioning, how to view and manage logs for each unit in a cluster, and provides some example log messages that are recorded during specific cluster events.

You configure logging for a cluster in the same way as you configuring logging for a standalone FortiGate unit. Log configuration changes made to the cluster are synchronized to all cluster units.

All cluster units record log messages separately to the individual cluster unit's log disk, to the cluster unit's system memory, or both. You can view and manage log messages for each cluster unit from the cluster web-based manager Log Access page.

When remote logging is configured, all cluster units send log messages to remote FortiAnalyzer units or other remote servers as configured. HA uses routing and inter-VDOM links to route subordinate unit log traffic through the primary unit to the network.

When you configure a FortiAnalyzer unit to receive log messages from a FortiGate cluster, you should add a cluster to the FortiAnalyzer unit configuration so that the FortiAnalyzer unit can receive log messages from all cluster units.

Viewing and managing log messages for individual cluster units

This section describes how to view and manage log messages for an individual cluster unit.

To view HA cluster log messages

1. Log into the cluster web-based manager.
2. Go to **Log&Report > Log Config > Log Settings > GUI Preferences** and select to display logs from **Memory**, **Disk or FortiAnalyzer**.
   For each log display, the **HA Cluster** list displays the serial number of the cluster unit for which log messages are displayed. The serial numbers are displayed in order in the list.
3. Set **HA Cluster** to the serial number of one of the cluster units to display log messages for that unit.

About HA event log messages

HA event log messages always include the host name and serial number of the cluster unit that recorded the message. HA event log messages also include the HA state of the unit and also indicate when a cluster unit switches (or moves) from one HA state to another. Cluster units can operate in the HA states listed below:

HA states

Hello	A FortiGate unit configured for HA operation has started up and is looking for other FortiGate units with which to form a cluster.
Work	In an active-passive cluster a cluster unit is operating as the primary unit. In an active-active cluster unit is operating as the primary unit or a subordinate unit.
Standby	In an active-passive cluster the cluster unit is operating as a subordinate unit.

HA log Event log messages also indicate the virtual cluster that the cluster unit is operating in as well as the member number of the unit in the cluster. If virtual domains are not enabled, all clusters unit are always operating in virtual cluster 1. If virtual domains are enabled, a cluster unit may be operating in virtual cluster 1 or virtual cluster 2. The member number indicates the position of the cluster unit in the cluster members list. Member 0 is the primary unit. Member 1 is the first subordinate unit, member 2 is the second subordinate unit, and so on.

HA log messages

See the FortiOS log message reference for a listing of and descriptions of the HA log messages.

FortiGate HA message "HA master heartbeat interface <intf_name> lost neighbor information"

The following HA log messages may be recorded by an operating cluster:

2009-02-16 11:06:34 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=critical vd=root msg="HA slave heartbeat interface internal lost neighbor information"

2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=notice vd=root msg="Virtual cluster 1 of group 0 detected new joined HA member"

2009-02-16 11:06:40 device_id=FG2001111111 log_id=0105035001 type=event subtype=ha pri=notice vd=root msg="HA master heartbeat interface internal get peer information"

These log messages indicate that the cluster units could not connect to each other over the HA heartbeat link for the period of time that is given by hb-interval x hb-lost-threshold, which is 1.2 seconds with the default values.

To diagnose this problem

1. Check all heartbeat interface connections including cables and switches to make sure they are connected and operating normally.
2. Use the following commands to display the status of the heartbeat interfaces.

   ```
   get hardware nic <heartbeat_interface_name>
   diagnose hardware deviceinfo nic <heartbeat_interface_name>
   ```

   The status information may indicate the interface status and link status and also indicate if a large number of errors have been detected.
3. If the log message only appears during peak traffic times, increase the tolerance for missed HA heartbeat packets by using the following commands to increase the lost heartbeat threshold and heartbeat interval:

   ```
   config system ha
      set hb-lost-threshold 12
      set hb-interval 4
   end
   ```

   These settings multiply by 4 the loss detection interval. You can use higher values as well.

   This condition can also occur if the cluster units are located in different buildings or even different geographical locations. Called a distributed cluster, as a result of the separation it may take a relatively long time for heartbeat packets to be transmitted between cluster units. You can support a distributed cluster by increasing the heartbeat interval so that the cluster expects extra time between heartbeat packets.
4. Optionally disable session-pickup to reduce the processing load on the heartbeat interfaces.
5. Instead of disabling session-pickup you can enable `session-pickup-delay` to reduce the number of sessions that are synchronized. With this option enabled only sessions that are active for more than 30 seconds are synchronized.

It may be useful to monitor CPU and memory usage to check for low memory and high CPU usage. You can configure event logging to monitor CPU and memory usage. You can also enable the CPU over usage and memory low SNMP events.

Once this monitoring is in place, try and determine if there have been any changes in the network or an increase of traffic recently that could be the cause. Check to see if the problem happens frequently and if so what the pattern is.

To monitor the CPU of the cluster units and troubleshoot further, use the following procedure and commands:

```
get system performance status
get system performance top 2
diagnose sys top 2
```

These commands repeated at frequent intervals will show the activity of the CPU and the number of sessions.

Search the Fortinet Knowledge Base for articles about monitoring CPU and Memory usage.

If the problem persists, gather the following information (a console connection might be necessary if connectivity is lost) and provide it to Technical Support when opening a ticket:

- Debug log from the web-based manager: **System > Config > Advanced > Download Debug Log**
- CLI command output:

```
diagnose sys top 2 (keep it running for 20 seconds)
get system performance status (repeat this command multiple times to get good samples)
get system ha status
diagnose sys ha status
diagnose sys ha dump-by {all options}
diagnose netlink device list
diagnose hardware deviceinfo nic <heartbeat-interface-name>
execute log filter category 1
execute log display
```

Formatting cluster unit hard disks (log disks)

If you need to format the hard disk (also called log disk or disk storage) of one or more cluster units you should disconnect the unit from the cluster and use the `execute formatlogdisk` command to format the cluster unit hard disk then add the unit back to the cluster.

For information about how to remove a unit from a cluster and add it back, see Disconnecting a cluster unit from a cluster on page 1451 and Adding a disconnected FortiGate unit back to its cluster on page 1452 .

Once you add the cluster unit with the formatted log disk back to the cluster you should make it the primary unit before removing other units from the cluster to format their log disks and then add them back to the cluster.

Clusters and SNMP

You can use SNMP to manage a cluster by configuring a cluster interface for SNMP administrative access. Using an SNMP manager you can get cluster configuration and status information and receive traps.

You configure SNMP for a cluster in the same way as configuring SNMP for a standalone FortiGate unit. SNMP configuration changes made to the cluster are shared by all cluster units.

Each cluster unit sends its own traps and SNMP manager systems can use SNMP get commands to query each cluster unit separately. To set SNMP get queries to each cluster unit you must create a special get command that includes the serial number of the cluster unit.

Alternatively you can use the HA reserved management interface feature to give each cluster unit a different management IP address. Then you can create an SNMP get command for each cluster unit that just includes the management IP address and does not have to include the serial number.

SNMP get command syntax for the primary unit

Normally, to get configuration and status information for a standalone FortiGate unit or for a primary unit, an SNMP manager would use an SNMP get commands to get the information in a MIB field. The SNMP get command syntax would be similar to the following:

```
snmpget -v2c -c <community_name> <address_ipv4> {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. The HA MIB fields and OIDs are listed below:

SNMP field names and OIDs

MIB field	OID	Description
fgHaSystemMode	.1.3.6.1.4.1.12356.101.13.1.1.0	HA mode (standalone, a-a, or a-p)
fgHaGroupId	.1.3.6.1.4.1.12356.101.13.1.2.0	The HA priority of the cluster unit. Default 128.
fgHaPriority	.1.3.6.1.4.1.12356.101.13.1.3.0	The HA priority of the cluster unit. Default 128.
fgHaOverride	.1.3.6.1.4.1.12356.101.13.1.4.0	Whether HA override is disabled or enabled for the cluster unit.
fgHaAutoSync	.1.3.6.1.4.1.12356.101.13.1.5.0	Whether automatic HA synchronization is disabled or enabled.
fgHaSchedule	.1.3.6.1.4.1.12356.101.13.1.6.0	The HA load balancing schedule. Set to none unless operating in a-p mode.
fgHaGroupName	.1.3.6.1.4.1.12356.101.13.1.7.0	The HA group name.
fgHaStatsIndex	.1.3.6.1.4.1.12356.101.13.2.1.1.1.1	The cluster index of the cluster unit. 1 for the primary unit, 2 to x for the subordinate units.
fgHaStatsSerial	.1.3.6.1.4.1.12356.101.13.2.1.1.2.1	The serial number of the cluster unit.
fgHaStatsCpuUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.3.1	The cluster unit's current CPU usage.
fgHaStatsMemUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.4.1	The cluster unit's current Memory usage.
fgHaStatsNetUsage	.1.3.6.1.4.1.12356.101.13.2.1.1.5.1	The cluster unit's current Network bandwidth usage.
fgHaStatsSesCount	.1.3.6.1.4.1.12356.101.13.2.1.1.6.1	The cluster unit's current session count.
fgHaStatsPktCount	.1.3.6.1.4.1.12356.101.13.2.1.1.7.1	The cluster unit's current packet count.
fgHaStatsByteCount	.1.3.6.1.4.1.12356.101.13.2.1.1.8.1	The cluster unit's current byte count.
fgHaStatsIdsCount	.1.3.6.1.4.1.12356.101.13.2.1.1.9.1	The number of attacks reported by the IPS for the cluster unit.
fgHaStatsAvCount	.1.3.6.1.4.1.12356.101.13.2.1.1.10.1	The number of viruses reported by the anti-virus system for the cluster unit.
fgHaStatsHostname	.1.3.6.1.4.1.12356.101.13.2.1.1.11.1	The hostname of the cluster unit.

To get the HA priority for the primary unit

The following SNMP get command gets the HA priority for the primary unit. The community name is `public`. The IP address of the cluster interface configured for SNMP management access is 10.10.10.1. The HA priority MIB field is fgHaPriority and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.1.3.0 The first command uses the MIB field name and the second uses the OID:

```
snmpget -v2c -c public 10.10.10.1 fgHaPriority
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.1.3.0
```

SNMP get command syntax for any cluster unit

To get configuration status information for a specific cluster unit (for the primary unit or for any subordinate unit), the SNMP manager must add the serial number of the cluster unit to the SNMP get command after the community name. The community name and the serial number are separated with a dash. The syntax for this SNMP get command would be:

```
snmpget -v2c -c <community_name>-<fgt_serial> <address_ipv4> {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community name to a FortiGate SNMP configuration. All units in the cluster have the same community name. The most commonly used community name is `public`.

`<fgt_serial>` is the serial number of any cluster unit. For example, FGT4002803033172. You can specify the serial number of any cluster unit, including the primary unit, to get information for that unit.

`<address_ipv4>` is the IP address of the FortiGate interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself.

If the serial number matches the serial number of a subordinate unit, the SNMP get request is sent over the HA heartbeat link to the subordinate unit. After processing the request, the subordinate unit sends the reply back over the HA heartbeat link back to the primary unit. The primary unit then forwards the response back to the SNMP manager.

If the serial number matches the serial number of the primary unit, the SNMP get request is processed by the primary unit. You can actually add a serial number to the community name of any SNMP get request. But normally you only need to do this for getting information from a subordinate unit.

To get the CPU usage for a subordinate unit

The following SNMP get command gets the CPU usage for a subordinate unit in a FortiGate-5001SX cluster. The subordinate unit has serial number FG50012205400050. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1. The HA status table MIB field is fgHaStatsCpuUsage and the OID for this MIB field is 1.3.6.1.4.1.12356.101.13.2.1.1.3.1. The first command uses the MIB field name and the second uses the OID for this table:

```
snmpget -v2c -c public-FG50012205400050 10.10.10.1 fgHaStatsCpuUsage
snmpget -v2c -c public-FG50012205400050 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.3.1
```

FortiGate SNMP recognizes the community name with syntax `<community_name>-<fgt_serial>`. When the primary unit receives an SNMP get request that includes the community name followed by serial number, the FGCP extracts the serial number from the request. Then the primary unit redirects the SNMP get request to the cluster unit with that serial number. If the serial number matches the serial number of the primary unit, the SNMP get is processed by the primary unit.

Getting serial numbers of cluster units

The following SNMP get commands use the MIB field name fgHaStatsSerial.<index> to get the serial number of each cluster unit. Where <index> is the cluster unit's cluster index and 1 is the cluster index of the primary unit, 2 is the cluster index of the first subordinate unit, and 3 is the cluster index of the second subordinate unit.

The OID for this MIB field is `1.3.6.1.4.1.12356.101.13.2.1.1.2.1`. The community name is `public`. The IP address of the FortiGate interface is 10.10.10.1.

The first command uses the MIB field name and the second uses the OID for this table and gets the serial number of the primary unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.1
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.1.1.2.1
```

The second command uses the MIB field name and the second uses the OID for this table and gets the serial number of the first subordinate unit:

```
snmpget -v2c -c public 10.10.10.1 fgHaStatsSerial.2
snmpget -v2c -c public 10.10.10.1 1.3.6.1.4.1.12356.101.13.2.2.2
```

SNMP get command syntax - reserved management interface enabled

To get configuration and status information for any cluster unit where you have enabled the HA reserved management interface feature and assigned IP addresses to the management interface of each cluster unit, an SNMP manager would use the following get command syntax:

```
snmpget -v2c -c <community_name> <mgmt_address_ipv4> {<OID> | <MIB_field>}
```

where:

`<community_name>` is an SNMP community name added to the FortiGate configuration. You can add more than one community names to a FortiGate SNMP configuration. The most commonly used community name is `public`.

`<mgmt_address_ipv4>` is the IP address of the FortiGate HA reserved management interface that the SNMP manager connects to.

`{<OID> | <MIB_field>}` is the object identifier (OID) for the MIB field or the MIB field name itself. To find OIDs and MIB field names see your FortiGate unit's online help.

Adding FortiClient licenses to a cluster

Each FortiGate unit in a cluster must have its own FortiClient license. Contact your reseller to purchase FortiClient licenses for all of the FortiGate units in your cluster.

When you receive the license keys you can log into the Fortinet Support site and add the FortiClient license keys to each FortiGate unit. Then, as long as the cluster can connect to the Internet each cluster unit receives its FortiClient license key from the FortiGuard network.

Adding FortiClient licenses to cluster units with a reserved management interface

You can also use the following steps to manually add license keys to your cluster units from the web-based manager or CLI. Your cluster must be connected to the Internet and you must have configured a reserved management interface for each cluster unit.

1. Log into the -web-based manager of each cluster unit using its reserved management interface IP address.
2. Go to the **License Information** dashboard widget and beside **FortiClient** select **Enter License**.

3. Enter the license key and select **OK**.
4. Confirm that the license has been installed and the correct number of FortiClients are licensed.
5. Repeat for all of the cluster units.

You can also use the reserved management IP address to log into each cluster unit CLI and use following command to add the license key:

```
execute FortiClient-NAC update-registration-license <license-key>
```

You can connect to the CLIs of each cluster unit using their reserved management IP address.

Adding FortiClient licenses to cluster units with no reserved management interface

If you have not set up reserved management IP addresses for your cluster units, you can still add FortiClient license keys to each cluster unit. You must log into the primary unit and then use the `execute ha manage` command to connect to each cluster unit CLI. For example, use the following steps to add a FortiClient license key a cluster of three FortiGate units:

1. Log into the primary unit CLI and enter the following command to confirm the serial number of the primary unit:
   ```
   get system status
   ```
2. Add the FortiClient license key for that serial number to the primary unit:
   ```
   execute FortiClient-NAC update-registration-license <license-key>
   ```
   You can also use the web-based manager to add the license key to the primary unit.
3. Enter the following command to log into the first subordinate unit:
   ```
   execute ha manage 1
   ```
4. Enter the following command to confirm the serial number of the cluster unit that you have logged into:
   ```
   get system status
   ```
5. Add the FortiClient license key for that serial number to the cluster unit:
   ```
   execute FortiClient-NAC update-registration-license <license-key>
   ```
6. Enter the following command to log into the second subordinate unit:
   ```
   execute ha manage 2
   ```
7. Enter the following command to confirm the serial number of the cluster unit that you have logged into:
   ```
   get system status
   ```
8. Add the FortiClient license key for that serial number to the cluster unit:
   ```
   execute FortiClient-NAC update-registration-license <license-key>
   ```

Viewing FortiClient license status and active FortiClient users for each cluster unit

To view FortiClient license status and FortiClient information for each cluster unit you must log into each cluster unit's web-based manager or CLI. You can do this by connecting to each cluster unit's reserved management interface if they are configured. If you have not configured reserved management interfaces you can use the execute ha manage command to log into each cluster unit CLI.

From the web-based manager, view FortiClient License status from the License Information dashboard widget and select **Details** to display the list of active FortiClient users connecting through that cluster unit. You can also see active FortiClient users by going to **User & Device > Monitor > FortiClient**.

From the CLI you can use the `execute FortiClient {list | info}` command to display FortiClient license status and active FortiClient users.

For example, use the following command to display the FortiClient license status of the cluster unit that you are logged into:

```
execute forticlient info
Maximum FortiClient connections: unlimited.
Licensed connections: 114
   NAC: 114
WANOPT: 0
Test: 0
Other connections:
   IPsec: 0
   SSLVPN: 0
```

Use the following command to display the list of active FortiClient users connecting through the cluster unit. The output shows the time the connection was established, the type of FortiClient connection, the name of the device, the user name of the person connecting, the FortiClient ID, the host operating system, and the source IP address of the session.

```
execute forticlient list
TIMESTAMP TYPE CONNECT-NAME USER CLIENT-ID HOST-OS SRC-IP

```

Cluster members list

To display the cluster members list, go to **System > Config > HA**.

The cluster members list displays illustrations of the front panels of the cluster units. If the network jack for an interface is shaded green, the interface is connected. Hover the mouse pointer over each illustration to view the cluster unit host name, serial number, and how long the unit has been operating (up time). The list of monitored interfaces is also displayed.

From the cluster members list you can:

- View HA statistics.
- Use the up and down arrows to change the order in which cluster units are listed.
- See the host name of each cluster unit. To change the primary unit host name, go to the system dashboard and select Change beside the current host name in the System Information widget. To view and change a subordinate unit host name, from the cluster members list select the edit icon for a subordinate unit.
- View the status or role of each cluster unit.
- View and optionally change the HA configuration of the operating cluster.
- View and optionally change the host name and device priority of a subordinate unit.
- Disconnect a cluster unit from a cluster.
- Download the Debug log for any cluster unit. You can send this debug log file to Fortinet Technical Support to help diagnose problems with the cluster or with individual cluster units.

Virtual cluster members list

If virtual domains are enabled, you can display the cluster members list to view the status of the operating virtual clusters. The virtual cluster members list shows the status of both virtual clusters including the virtual domains added to each virtual cluster.

To display the virtual cluster members list for an operating cluster log in as the admin administrator, select Global Configuration and go to **System > Config > HA**.

The functions of the virtual cluster members list are the same as the functions of the Cluster Members list with the following exceptions.

- When you select the edit icon for a primary unit in a virtual cluster, you can change the virtual cluster 1 and virtual cluster 2 device priority of this cluster unit and you can edit the VDOM partitioning configuration of the cluster.
- When you select the edit icon for a subordinate unit in a virtual cluster, you can change the device priority for the subordinate unit for the selected virtual cluster.

Also, the HA cluster members list changes depending on the cluster unit that you connect to.

Viewing HA statistics

From the cluster members list you can select **View HA statistics** to display the serial number, status, and monitor information for each cluster unit. To view HA statistics, go to **System > Config > HA** and select View HA Statistics. Note the following about the HA statistics display:

- Use the serial number ID to identify each FortiGate unit in the cluster. The cluster ID matches the FortiGate unit serial number.
- Status indicates the status of each cluster unit. A green check mark indicates that the cluster unit is operating normally. A red X indicates that the cluster unit cannot communicate with the primary unit.
- The up time is the time in days, hours, minutes, and seconds since the cluster unit was last started.
- The web-based manager displays CPU usage for core processes only. CPU usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.
- The web-based manager displays memory usage for core processes only. Memory usage for management processes (for example, for HTTPS connections to the web-based manager) is excluded.

Changing the HA configuration of an operating cluster

To change the configuration settings of an operating cluster, go to **System > Config > HA** to display the cluster members list. Select Edit for the master (or primary) unit in the cluster members list to display the HA configuration page for the cluster.

You can use the HA configuration page to check and fine tune the configuration of the cluster after the cluster is up and running. For example, if you connect or disconnect cluster interfaces you may want to change the Port Monitor configuration.

Any changes you make on this page, with the exception of changes to the device priority, are first made to the primary unit configuration and then synchronized to the subordinate units. Changing the device priority only affects the primary unit.

Changing the HA configuration of an operating virtual cluster

To change the configuration settings of the primary unit in a functioning cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > Config > HA** to display the cluster members list. Select Edit for the master (or primary) unit in virtual cluster 1 or virtual cluster 2 to display the HA configuration page for the virtual cluster.

You can use the virtual cluster HA configuration page to check and fine tune the configuration of both virtual clusters after the cluster is up and running. For example, you may want to change the Port Monitor configuration for virtual cluster 1 and virtual cluster 2 so that each virtual cluster monitors its own interfaces.

You can also use this configuration page to move virtual domains between virtual cluster 1 and virtual cluster 2. Usually you would distribute virtual domains between the two virtual clusters to balance the amount of traffic being processed by each virtual cluster.

Any changes you make on this page, with the exception of changes to the device priorities, are first made to the primary unit configuration and then synchronized to the subordinate unit.

You can also adjust device priorities to configure the role of this cluster unit in the virtual cluster. For example, to distribute traffic to both cluster units in the virtual cluster configuration, you would want one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. You can create this configuration by setting the device priorities. The cluster unit with the highest device priority in virtual cluster 1 becomes the primary unit for virtual cluster 1. The cluster unit with the highest device priority in virtual cluster 2 becomes the primary unit in virtual cluster 2.

Changing the subordinate unit host name and device priority

To change the host name and device priority of a subordinate unit in an operating cluster, go to **System > Config > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

To change the host name and device priority of a subordinate unit in an operating cluster with virtual domains enabled, log in as the admin administrator, select Global Configuration and go to **System > Config > HA** to display the cluster members list. Select Edit for any slave (subordinate) unit in the cluster members list.

You can change the host name (Peer) and device priority (Priority) of this subordinate unit. These changes only affect the configuration of the subordinate unit.

The device priority is not synchronized among cluster members. In a functioning cluster you can change device priority to change the priority of any unit in the cluster. The next time the cluster negotiates, the cluster unit with the highest device priority becomes the primary unit.

The device priority range is 0 to 255. The default device priority is 128.

Upgrading cluster firmware

You can upgrade the FortiOS firmware running on an HA cluster in the same manner as upgrading the firmware running on a standalone FortiGate unit. During a normal firmware upgrade, the cluster upgrades the primary unit and all subordinate units to run the new firmware image. The firmware upgrade takes place without interrupting communication through the cluster.

Upgrading cluster firmware to a new major release (for example upgrading from 5.0 MRx to 5.2.2) is supported for clusters. Make sure you are taking an upgrade path described in the release notes. Even so you should back up your configuration and only perform such a firmware upgrade during a maintenance window.

To upgrade the firmware without interrupting communication through the cluster, the cluster goes through a series of steps that involve first upgrading the firmware running on the subordinate units, then making one of the subordinate units the primary unit, and finally upgrading the firmware on the former primary unit. These steps are transparent to the user and the network, but depending upon your HA configuration may result in the cluster selecting a new primary unit.

The following sequence describes in detail the steps the cluster goes through during a firmware upgrade and how different HA configuration settings may affect the outcome.

1. The administrator uploads a new firmware image from the web-based manager or CLI.
2. If the cluster is operating in active-active mode load balancing is turned off.
3. The cluster upgrades the firmware running on all of the subordinate units.
4. Once the subordinate units have been upgraded, a new primary unit is selected.

   This primary unit will be running the new upgraded firmware.
5. The cluster now upgrades the firmware of the former primary unit.

   If the age of the new primary unit is more than 300 seconds (5 minutes) greater than the age of all other cluster units, the new primary unit continues to operate as the primary unit.

   This is the intended behavior but does not usually occur because the age difference of the cluster units is usually less than the cluster age difference margin of 300 seconds. So instead, the cluster negotiates again to select a primary unit as described in An introduction to the FGCP on page 1270.

   You can keep the cluster from negotiating again by reducing the cluster age difference margin using the `ha-uptime-diff-margin` option. However, you should be cautious when reducing the age or other problems may occur. For information about the cluster age difference margin, see An introduction to the FGCP on page 1270. For more information about changing the cluster age margin, see An introduction to the FGCP on page 1270.
6. If the cluster is operating in active-active mode, load balancing is turned back on.

Changing how the cluster processes firmware upgrades

By default cluster firmware upgrades proceed as uninterruptable upgrades that do not interrupt traffic flow. If required, you can use the following CLI command to change how the cluster handles firmware upgrades. You might want to change this setting if you are finding uninterruptable upgrades take too much time.

```
config system ha
   set uninterruptible-upgrade disable
end
```

`uninterruptible-upgrade` is enabled by default. If you disable `uninterruptible-upgrade` the cluster still upgrades the firmware on all cluster units, but all cluster units are upgraded at once; which takes less time but interrupts communication through the cluster.

Synchronizing the firmware build running on a new cluster unit

If the firmware build running on a FortiGate unit that you add to a cluster is older than the cluster firmware build, you may be able to use the following steps to synchronize the firmware running on the new cluster unit.

This procedure describes re-installing the same firmware build on a cluster to force the cluster to upgrade all cluster units to the same firmware build.

Due to firmware upgrade and synchronization issues, in some cases this procedure may not work. In all cases it will work to install the same firmware build on the new unit as the one that the cluster is running before adding the new unit to the cluster.

To synchronize the firmware build running on a new cluster unit

1. Obtain a firmware image that is the same as build already running on the cluster.
2. Connect to the cluster using the web-based manager.
3. Go to the **System Information** dashboard widget.
4. Select **Update** beside **Firmware Version**.
   You can also install a newer firmware build.
5. Select **OK**.
   After the firmware image is uploaded to the cluster, the primary unit upgrades all cluster units to this firmware build.

Downgrading cluster firmware

For various reasons you may need to downgrade the firmware that a cluster is running. You can use the information in this section to downgrade the firmware version running on a cluster.

In most cases you can downgrade the firmware on an operating cluster using the same steps as for a firmware upgrade. A warning message appears during the downgrade but the downgrade usually works and after the downgrade the cluster continues operating normally with the older firmware image.

Downgrading between some firmware versions, especially if features have changed between the two versions, may not always work without the requirement to fix configuration issues after the downgrade.

Only perform firmware downgrades during maintenance windows and make sure you back up your cluster configuration before the downgrade.

If the firmware downgrade that you are planning may not work without configuration loss or other problems, you can use the following downgrade procedure to make sure your configuration is not lost after the downgrade.

To downgrade cluster firmware

This example shows how to downgrade the cluster shown in Example NAT/Route mode HA network topology. The cluster consists of two cluster units (FGT_ha_1 and FGT_ha_2). The port1 and port2 interfaces are connected to networks and the port3 and port4 interfaces are connected together for the HA heartbeat.

This example, describes separating each unit from the cluster and downgrading the firmware for the standalone FortiGate units. There are several ways you could disconnect units from the cluster. This example describes using the disconnect from cluster function on the cluster members list GUI page.

1. Go to the **System Information** dashboard widget and backup the cluster configuration.
   From the CLI use `execute backup config`.
2. Go to **System > Config > HA** and for FGT_ha_1 select the **Disconnect from cluster** icon.
3. Select the port2 interface and enter an IP address and netmask of 10.11.101.101/24 and select **OK**.
   From the CLI you can enter the following command (FG600B3908600705 is the serial number of the

cluster unit) to be able to manage the standalone FortiGate unit by connecting to the port2 interface with IP address and netmask 10.11.101.101/24.

```
execute ha disconnect FG600B3908600705 port2 10.11.101.101/24
```

After FGT_ha_1 is disconnected, FGT_ha_2 continues processing traffic.

4. Connect to the FGT_ha_1 web-based manager or CLI using IP address 10.11.101.101/24 and follow normal procedures to downgrade standalone FortiGate unit firmware.
5. When the downgrade is complete confirm that the configuration of 620_ha_1 is correct.
6. Set the HA mode of FGT_ha_2 to Standalone and follow normal procedures to downgrade standalone FortiGate unit firmware.

   Network communication will be interrupted for a short time during the downgrade.
7. When the downgrade is complete confirm that the configuration of FGT_ha_2 is correct.
8. Set the HA mode of FGT_ha_2 to Active-Passive or the required HA mode.
9. Set the HA mode of FGT_ha_1 to the same mode as FGT_ha_2.

   If you have not otherwise changed the HA settings of the cluster units and if the firmware downgrades have not affected the configurations the units should negotiate and form cluster running the downgraded firmware.

Backing up and restoring the cluster configuration

You can backup the configuration of the primary unit by logging into the web-based manager or CLI and following normal configuration backup procedures.

The following configuration settings are not synchronized to all cluster units:

- HA override and priority
- The interface configuration of the HA reserved management interface (`config system interface`)
- The HA reserved management interface default IPv4 route (`ha-mgmt-interface-gateway`)
- The HA reserved management interface default IPv6 route (`ha-mgmt-interface-gateway6`)
- The FortiGate unit host name.

To backup these configuration settings for each cluster unit you must log into each cluster unit and backup its configuration.

If you need to restore the configuration of the cluster including the configuration settings that are not synchronized you should first restore the configuration of the primary unit and then restore the configuration of each cluster unit. Alternatively you could log into each cluster unit and manually add the configuration settings that were not restored.

Monitoring cluster units for failover

If the primary unit in the cluster fails, the units in the cluster renegotiate to select a new primary unit. Failure of the primary unit results in the following:

- If SNMP is enabled, the new primary unit sends HA trap messages. The messages indicate a cluster status change, HA heartbeat failure, and HA member down.
- If event logging is enabled and HA activity event is selected, the new primary unit records log messages that show that the unit has become the primary unit.

- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed primary unit no longer appears on the Cluster Members list.
- The host name and serial number of the primary unit changes. You can see these changes when you log into the web-based manager or CLI.
- The cluster info displayed on the dashboard, cluster members list or from the `get system ha status` command changes.

If a subordinate unit fails, the cluster continues to function normally. Failure of a subordinate unit results in the following:

- If event logging is enabled and HA activity event is selected, the primary unit records log messages that show that a subordinate has been removed from the cluster.
- If alert email is configured to send email for HA activity events, the new primary unit sends an alert email containing the log message recorded by the event log.
- The cluster contains fewer FortiGate units. The failed unit no longer appears on the Cluster Members list.

Viewing cluster status from the CLI

Use the `get system ha status` command to display information about an HA cluster. The command displays general HA configuration settings. The command also displays information about how the cluster unit that you have logged into is operating in the cluster.

Usually you would log into the primary unit CLI using SSH or telnet. In this case the `get system ha status` command displays information about the primary unit first, and also displays the HA state of the primary unit (the primary unit operates in the work state). However, if you log into the primary unit and then use the `execute ha manage` command to log into a subordinate unit, (or if you use a console connection to log into a subordinate unit) the `get system status` command displays information about this subordinate unit first, and also displays the HA state of this subordinate unit. The state of a subordinate unit is work for an active-active cluster and standby for an active-passive cluster.

For a virtual cluster configuration, the `get system ha status` command displays information about how the cluster unit that you have logged into is operating in virtual cluster 1 and virtual cluster 2. For example, if you connect to the cluster unit that is the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2, the output of the `get system ha status` command shows virtual cluster 1 in the work state and virtual cluster 2 in the standby state. The `get system ha status` command also displays additional information about virtual cluster 1 and virtual cluster 2.

The command display includes the following fields.

Fields	Description
`Model`	The FortiGate model number.
`Mode`	The HA mode of the cluster: a-a or a-p.
`Group`	The group ID of the cluster.
`Debug`	The debug status of the cluster.
`ses_pickup`	The status of session pickup: enable or disable.
`load balance`	The status of the `load-balance-all` keyword: enable or disable. Relevant to active-active clusters only.
`schedule`	The active-active load balancing schedule. Relevant to active-active clusters only.
`Master Slave`	`Master` displays the device priority, host name, serial number, and cluster index of the primary (or master) unit. `Slave` displays the device priority, host name, serial number, and cluster index of the subordinate (or slave, or backup) unit or units. The list of cluster units changes depending on how you log into the CLI. Usually you would use SSH or telnet to log into the primary unit CLI. In this case the primary unit would be at the top the list followed by the other cluster units. If you use `execute ha manage` or a console connection to log into a subordinate unit CLI, and then enter `get system ha status` the subordinate unit that you have logged into appears at the top of the list of cluster units.
`number of vcluster`	The number of virtual clusters. If virtual domains are not enabled, the cluster has one virtual cluster. If virtual domains are enabled the cluster has two virtual clusters.

Fields	Description
	The HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 1. If virtual domains are not enabled, `vcluster 1` displays information for the cluster. If virtual domains are enabled, `vcluster 1` displays information for virtual cluster 1. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 1 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 1. `vcluster 1` also lists the primary unit (master) and subordinate units (slave) in virtual cluster 1. The list includes the cluster index and serial number of each cluster unit in virtual cluster 1. The cluster unit that you have logged into is at the top of the list.
`vcluster 1` `Master Slave`	If virtual domains are not enabled and you connect to the primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the primary unit. If virtual domains are not enabled and you connect to a subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you have logged into. If virtual domains are enabled and you connect to the virtual cluster 1 primary unit CLI, the HA state of the cluster unit in virtual cluster 1 is work. The display lists the cluster units starting with the virtual cluster 1 primary unit. If virtual domains are enabled and you connect to the virtual cluster 1 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 1 is standby. The display lists the cluster units starting with the subordinate unit that you are logged into.
`vcluster 2` `Master Slave`	`vcluster 2` only appears if virtual domains are enabled. `vcluster 2` displays the HA state (hello, work, or standby) and HA heartbeat IP address of the cluster unit that you have logged into in virtual cluster 2. The HA heartbeat IP address is 169.254.0.2 if you are logged into the primary unit of virtual cluster 2 and 169.254.0.1 if you are logged into a subordinate unit of virtual cluster 2. `vcluster 2` also lists the primary unit (master) and subordinate units (slave) in virtual cluster 2. The list includes the cluster index and serial number of each cluster unit in virtual cluster 2. The cluster unit that you have logged into is at the top of the list. If you connect to the virtual cluster 2 primary unit CLI, the HA state of the cluster unit in virtual cluster 2 is `work`. The display lists the cluster units starting with the virtual cluster 2 primary unit. If you connect to the virtual cluster 2 subordinate unit CLI, the HA state of the cluster unit in virtual cluster 2 is `standby`. The display lists the cluster units starting with the subordinate unit that you are logged into.

Examples

The following example shows `get system ha status` output for a cluster of two FortiGate-5001SX units operating in active-active mode. The cluster group ID, session pickup, load balance all, and the load balancing schedule are all set to the default values. The device priority of the primary unit is also set to the default value. The device priority of the subordinate unit has been reduced to 100. The host name of the primary unit is `5001_Slot_4`. The host name of the subordinate unit in is `5001_Slot_3`.

The command output was produced by connecting to the primary unit CLI (host name `5001_Slot_4`).

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4 FG50012204400045 1
Slave :100 5001_Slot_3 FG50012205400050 0
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
```

The following command output was produced by using `execute HA manage 0` to log into the subordinate unit CLI of the cluster shown in the previous example. The host name of the subordinate unit is `5001_Slot_3`.

```
Model: 5000
Mode: a-a
Group: 0
Debug: 0
ses_pickup: disable
load_balance: disable
schedule: round robin
Slave :100 5001_Slot_3 FG50012205400050 0
Master:128 5001_Slot_4 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.2
Slave :1 FG50012205400050
Master:0 FG50012204400045
```

The following example shows `get system ha status` output for a cluster of three FortiGate-5001 units operating in active-passive mode. The cluster group ID is set to 20 and session pickup is enabled. Load balance all and the load balancing schedule are set to the default value. The device priority of the primary unit is set to 200. The device priorities of the subordinate units are set to 128 and 100. The host name of the primary unit is `5001_Slot_5`. The host names of the subordinate units are `5001_Slot_3` and `5001_Slot_4`.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:200 5001_Slot_5 FG50012206400112 0
Slave :100 5001_Slot_3 FG50012205400050 1
Slave :128 5001_Slot_4 FG50012204400045 2
number of vcluster: 1
```

```
vcluster 1: work 169.254.0.1
Master:0 FG50012206400112
Slave :1 FG50012204400045
Slave :2 FG50012205400050
```

The following example shows `get system ha status` output for a cluster of two FortiGate-5001 units with virtual clustering enabled. This command output was produced by logging into the primary unit for virtual cluster 1 (hostname: 5001_Slot_4, serial number FG50012204400045).

The virtual clustering output shows that the cluster unit with host name 5001_Slot_4 and serial number FG50012204400045 is operating as the primary unit for virtual cluster 1 and the subordinate unit for virtual cluster 2.

For virtual cluster 1 the cluster unit that you have logged into is operating in the work state and the serial number of the primary unit for virtual cluster 1 is FG50012204400045. For virtual cluster 2 the cluster unit that you have logged into is operating in the standby state and the serial number of the primary unit for virtual cluster 2 is FG50012205400050.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4 FG50012204400045 1
Slave :100 5001_Slot_3 FG50012205400050 0
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
vcluster 2: standby 169.254.0.1
Slave :1 FG50012204400045
Master:0 FG50012205400050
```

The following example shows `get system ha status` output for the same cluster as shown in the previous example after using `execute ha manage 0` to log into the primary unit for virtual cluster 2 (hostname: 5001_Slot_3, serial number FG50012205400050).

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Slave :100 5001_Slot_3 FG50012205400050 0
Master:128 5001_Slot_4 FG50012204400045 1
number of vcluster: 2
vcluster 1: standby 169.254.0.2
Slave :1 FG50012205400050
Master:0 FG50012204400045
vcluster 2: work 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

The following example shows `get system ha status` output for a virtual cluster configuration where the cluster unit with hostname: 5001_Slot_4 and serial number FG50012204400045 is the primary unit for both

virtual clusters. This command output is produced by logging into cluster unit with host name 5001_Slot_4 and serial number FG50012204400045.

```
Model: 5000
Mode: a-p
Group: 20
Debug: 0
ses_pickup: enable
load_balance: disable
schedule: round robin
Master:128 5001_Slot_4 FG50012204400045 1
Slave :100 5001_Slot_3 FG50012205400050 0
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
vcluster 2: work 169.254.0.2
Master:0 FG50012204400045
Slave :1 FG50012205400050
```

About the HA cluster index and the execute ha manage command

When a cluster starts up, the FortiGate Cluster Protocol (FGCP) assigns a cluster index and a HA heartbeat IP address to each cluster unit based on the serial number of the cluster unit. The FGCP selects the cluster unit with the highest serial number to become the primary unit. The FGCP assigns a cluster index of 0 and an HA heartbeat IP address of 169.254.0.1 to this unit. The FGCP assigns a cluster index of 1 and an HA heartbeat IP address of 169.254.0.2 to the cluster unit with the second highest serial number. If the cluster contains more units, the cluster unit with the third highest serial number is assigned a cluster index of 2 and an HA heartbeat IP address of 169.254.0.3, and so on. You can display the cluster index assigned to each cluster unit using the `get system ha status` command. Also when you use the `execute ha manage` command you select a cluster unit to log into by entering its cluster index.

The cluster index and HA heartbeat IP address only change if a unit leaves the cluster or if a new unit joins the cluster. When one of these events happens, the FGCP resets the cluster index and HA heartbeat IP address of each cluster unit according to serial number in the same way as when the cluster first starts up.

Each cluster unit keeps its assigned cluster index and HA heartbeat IP address even as the units take on different roles in the cluster. After the initial cluster index and HA heartbeat IP addresses are set according to serial number, the FGCP checks other primary unit selection criteria such as device priority and monitored interfaces. Checking these criteria could result in selecting a cluster unit without the highest serial number to operate as the primary unit.

Even if the cluster unit without the highest serial number now becomes the primary unit, the cluster indexes and HA heartbeat IP addresses assigned to the individual cluster units do not change. Instead the FGCP assigns a second cluster index, which could be called the operating cluster index, to reflect this role change. The operating cluster index is 0 for the primary unit and 1 and higher for the other units in the cluster. By default both sets of cluster indexes are the same. But if primary unit selection selects the cluster unit that does not have the highest serial number to be the primary unit then this cluster unit is assigned an operating cluster index of 0. The operating cluster index is used by the FGCP only. You can display the operating cluster index assigned to each cluster unit using the `get system ha status` command. There are no CLI commands that reference the operating cluster index.

Even though there are two cluster indexes there is only one HA heartbeat IP address and the HA heartbeat address is not affected by a change in the operating cluster index.

Using the execute ha manage command

When you use the CLI command `execute ha manage <index_integer>` to connect to the CLI of another cluster unit, the `<index_integer>` that you enter is the cluster index of the unit that you want to connect to.

Using get system ha status to display cluster indexes

You can display the cluster index assigned to each cluster unit using the CLI command `get system ha status`. The following example shows the information displayed by the `get system ha status` command for a cluster consisting of two FortiGate-5001SX units operating in active-passive HA mode with virtual domains not enabled and without virtual clustering.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :128 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

In this example, the cluster unit with serial number FG50012205400050 has the highest serial number and so has a cluster index of 0 and the cluster unit with serial number FG50012204400045 has a cluster index of 1. From the CLI of the primary (or master) unit of this cluster you can connect to the CLI of the subordinate (or slave) unit using the following command:

```
execute ha manage 1
```

This works because the cluster unit with serial number FG50012204400045 has a cluster index of 1.

The `get system ha status` command output shows two similar lists of indexes and serial numbers. The listing on the sixth and seventh lines of the command output are the cluster indexes assigned according to cluster unit serial number. These are the cluster indexes that you enter when using the `execute ha manage` command. The cluster indexes shown in the last two lines of the command output are the operating cluster indexes that reflect how the cluster units are actually operating in the cluster. In this example both sets of cluster indexes are the same.

The last three lines of the command output display the status of vcluster 1. In a cluster consisting of two cluster units operating without virtual domains enabled all clustering actually takes place in virtual cluster 1. HA is designed to work this way to support virtual clustering. If this cluster was operating with virtual domains enabled, adding virtual cluster 2 is similar to adding a new copy of virtual cluster 1. Virtual cluster 2 is visible in the `get system ha status` command output when you add virtual domains to virtual cluster 2.

The HA heartbeat IP address displayed on line 8 is the HA heartbeat IP address of the cluster unit that is actually operating as the primary unit. For a default configuration this IP address will always be 169.254.0.1 because the cluster unit with the highest serial number will be the primary unit. This IP address changes if the operating primary unit is not the primary unit with the highest serial number.

Example actual and operating cluster indexes do not match

This example shows get system ha status command output for same cluster of two FortiGate-5001SX units. However, in this example the device priority of the cluster unit with the serial number FG50012204400045 is increased to 200. As a result the cluster unit with the lowest serial number becomes the primary unit. This means the actual and operating cluster indexes of the cluster units do not match.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 1
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
```

The actual cluster indexes have not changed but the operating cluster indexes have. Also, the HA heartbeat IP address displayed for vcluster 1 has changed to 169.254.0.2.

Virtual clustering example output

The `get system ha status` command output is the same if a cluster is operating with virtual clustering turned on but with all virtual domains in virtual cluster 1. The following `get system ha status` command output example shows the same cluster operating as a virtual cluster with virtual domains in virtual cluster 1 and added to virtual cluster 2. In this example the cluster unit with serial number FG50012204400045 is the primary unit for virtual cluster 1 and the cluster unit with serial number FG50012205400050 is the primary unit for virtual cluster 2.

```
get system ha status
Model: 5000
Mode: a-p
Group: 0
Debug: 0
ses_pickup: disable
Master:128 5001_slot_7 FG50012205400050 0
Slave :200 5001_slot_11 FG50012204400045 1
number of vcluster: 2
vcluster 1: work 169.254.0.2
Master:1 FG50012205400050
Slave :0 FG50012204400045
vcluster 2: standby 169.254.0.1
Master:0 FG50012205400050
Slave :1 FG50012204400045
```

This example shows three sets of indexes. The indexes in lines six and seven are still used by the `execute ha manage` command. The indexes on lines ten and eleven are for the primary and subordinate units in virtual cluster 1 and the indexes on the last two lines are for virtual cluster 2.

Managing individual cluster units

The following procedure describes how to use SSH to log into the primary unit CLI and from there to use the `execute ha manage` command to connect to the CLI of any other unit in the cluster. The procedure is very similar if you use telnet, or the web-based manager dashboard CLI console.

You can use the `execute ha manage` command from the CLI of any cluster unit to log into the CLI of another the cluster unit. Usually you would use this command from the CLI of the primary unit to log into the CLI of a subordinate unit. However, if you have logged into a subordinate unit CLI, you can use this command to log into the primary unit CLI, or the CLI of another subordinate unit.

Using SSH or telnet or the web-based manager dashboard CLI console you can only log into the primary unit CLI. Using a direct console connection you can log into any cluster unit. In both cases you can use `execute ha manage` to connect to the CLI of other cluster units.

1. Use SSH to connect to the cluster and log into the primary unit CLI.
   Connect to any cluster interface configured for SSH administrative access to log into the cluster.
2. Enter the following command followed by a space and type a question mark (`?`):
   ```
   execute ha manage
   ```
   The CLI displays a list of all the subordinate units in the cluster. Each cluster unit is numbered, starting at 1. The information displayed for each cluster unit includes the unit serial number and the host name of the unit.
3. Complete the command with the number of the subordinate unit to log into. For example, to log into subordinate unit 1, enter the following command:
   ```
   execute ha manage 1
   ```
   Press Enter to connect to and use an administrator account to log into the CLI of the selected subordinate unit. If this subordinate unit has a different host name, the CLI prompt changes to this host name.

   You can use CLI commands to manage this subordinate unit. If you make changes to the configuration of any cluster unit (primary or subordinate unit) these changes are synchronized to all cluster units.
4. You can now use the `execute ha manage` command to connect to any other cluster unit (including the primary unit). You can also use the `exit` command to return to the primary unit CLI.

Disconnecting a cluster unit from a cluster

Use the following procedures to disconnect a cluster unit from a functioning cluster without disrupting the operation of the cluster. You can disconnect a cluster unit if you need to use the disconnected FortiGate unit for another purpose, such as to act as a standalone firewall.

You can use the following procedures for a standard cluster and for a virtual clustering configuration. To use the following procedures from a virtual cluster you must be logged in as the admin administrator and you must have selected Global Configuration.

When you disconnect a cluster unit you must assign an IP address and netmask to one of the interfaces of the disconnected unit. You can disconnect any unit from the cluster even the primary unit. After the unit is disconnected, the cluster responds as if the disconnected unit has failed. The cluster may renegotiate and may select a new primary unit.

When the cluster unit is disconnected the HA mode is changed to standalone. In addition, all interface IP addresses of the disconnected unit are set to 0.0.0.0 except for the interface that you configure.

Otherwise the configuration of the disconnected unit is not changed. The HA configuration of the disconnected unit is not changed either (except to change the HA mode to Standalone).

To disconnect a cluster unit from a cluster - web-based manager

1. Go to **System > Config > HA** to view the cluster members list.
2. Select the Disconnect from cluster icon for the cluster unit to disconnect from the cluster.
3. Select the interface that you want to configure. You also specify the IP address and netmask for this interface. When the FortiGate unit is disconnected, all management access options are enabled for this interface.
4. Specify an IP address and netmask for the interface. You can use this IP address to connect to the interface to configure the disconnected FortiGate unit.
5. Select **OK**.

   The FortiGate unit is disconnected from the cluster and the cluster may renegotiate and select a new primary unit. The selected interface of the disconnected unit is configured with the specified IP address and netmask.

To disconnect a cluster unit from a cluster - CLI

1. Enter the following command to disconnect a cluster unit with serial number FGT5002803033050. The internal interface of the disconnected unit is set to IP address 1.1.1.1 and netmask 255.255.255.0.

```
execute ha disconnect FGT5002803033050 internal 1.1.1.1 255.255.255.0
```

Adding a disconnected FortiGate unit back to its cluster

If you disconnect a FortiGate unit from a cluster, you can re-connect the disconnected FortiGate unit to the cluster by setting the HA mode of the disconnected unit to match the HA mode of the cluster. Usually the disconnected unit rejoins the cluster as a subordinate unit and the cluster automatically synchronizes its configuration.

You do not have to change the HA password on the disconnected unit unless the HA password has been changed after the unit was disconnected. Disconnecting a unit from a cluster does not change the HA password.

You should make sure that the device priority of the disconnected unit is lower than the device priority of the current primary unit. You should also make sure that the HA `override` CLI option is not enabled on the disconnected unit. Otherwise, when the disconnected unit joins the cluster, the cluster will renegotiate and the disconnected unit may become the primary unit. If this happens, the configuration of the disconnected unit is synchronized to all other cluster units. This configuration change might disrupt the operation of the cluster.

The following procedure assumes that the disconnected FortiGate unit is correctly physically connected to your network and to the cluster but is not running in HA mode and not part of the cluster.

Before you start this procedure you should note the device priority of the primary unit.

To add a disconnected FortiGate unit back to its cluster - web-based manager

1. Log into the disconnected FortiGate unit.
   If virtual domains are enabled, log in as the admin administrator and select Global Configuration.
2. Go to **System > Config > HA**.
3. Change Mode to match the mode of the cluster.
4. If required, change the group name and password to match the cluster.
5. Set the Device Priority lower than the device priority of the primary unit.
6. Select **OK**.
   The disconnected FortiGate unit joins the cluster.

To add a disconnected FortiGate unit back to its cluster - CLI

1. Log into the CLI of the FortiGate unit to be added back to the cluster.
2. Enter the following command to access the global configuration and add the FortiGate unit back to a cluster operating in active-passive mode and set the device priority to 50 (a low number) so that this unit will not become the primary unit:

```
config global
   config system ha
      set mode a-p
      set priority 50
   end
end
```

   You may have to also change the group name, group id and password. However if you have not changed these for the cluster or the FortiGate unit after it was disconnected from the cluster you should not have to adjust them now.

HA diagnose commands

You can use the following diagnose command to display a data about a cluster:

```
diagnose sys ha dump-by {all-xdb | all-vcluster| rcache | all-group |
   memory | debug-zone | vdom | kernel | device | stat| sesync}
```

The example out put below is from a cluster of two FortiGate-5001Cs. In this cluster the base1 and base2 interfaces communicate the HA heartbeat and port monitoring has been added to poort1.

all-xdb

This command displays information about the current configuration of the cluster and how its operating. You can use the out to determine the primary unit, the state of port monitoring as well as most cluster configuration details and status.

```
diagnose sys ha dump-by all-xdb
HA information.
idx=1,nxentry=2,linkfails=7,flags=0,digest=7.72.e3.2e.8e.d1...

```

stat

This command displays some statistics about how well the cluster is functioning. Information includes packet counts, memory use, failed links and ping failures.

```
diagnose sys ha dump-by stat
HA information.
packet count = 1, memory = 220.
check_linkfails = 0, linkfails = 0, check_pingsvrfails = 2822
bufcnt = -5, bufmem = 0
```

HA and failover protection

In FortiGate active-passive HA, the FortiGate Clustering Protocol (FGCP) provides failover protection. This means that an active-passive cluster can provide FortiGate services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-aloneFortiGate unit. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially in a mission-critical environment.

The FGCP supports three kinds of failover protection. Device failover automatically replaces a failed device and restarts traffic flow with minimal impact on the network. Link failover maintains traffic flow if a link fails. Session failover resumes communication sessions with minimal loss of data if a device or link failover occurs.

This chapter describes how FGCP failover protection works and provides detailed NAT/Route and Transparent mode packet flow descriptions.

About active-passive failover

To achieve failover protection in an active-passive cluster, one of the cluster units functions as the primary unit, while the rest of the cluster units are subordinate units, operating in an active stand-by mode. The cluster IP addresses and HA virtual MAC addresses are associated with the cluster interfaces of the primary unit. All traffic directed at the cluster is actually sent to and processed by the primary unit.

While the cluster is functioning, the primary unit functions as the FortiGate network security device for the networks that it is connected to. In addition, the primary unit and subordinate units use the HA heartbeat to keep in constant communication. The subordinate units report their status to the cluster unit and receive and store connection and state table updates.

Device failure

If the primary unit encounters a problem that is severe enough to cause it to fail, the remaining cluster units negotiate to select a new primary unit. This occurs because all of the subordinate units are constantly waiting to negotiate to become primary units. Only the heartbeat packets sent by the primary unit keep the subordinate units from becoming primary units. Each received heartbeat packet resets negotiation timers in the subordinate units. If this timer is allowed to run out because the subordinate units do not receive heartbeat packets from the primary unit, the subordinate units assume that the primary unit has failed, and negotiate to become primary units themselves.

Using the same FGCP negotiation process that occurs when the cluster starts up, after they determine that the primary unit has failed, the subordinate units negotiate amongst themselves to select a new primary unit. The subordinate unit that wins the negotiation becomes the new primary unit with the same MAC and IP addresses as the former primary unit. The new primary unit then sends gratuitous ARP packets out all of its interfaces to inform attached switches to send traffic to the new primary unit. Sessions then resume with the new primary unit.

Link failure

If a primary unit interface fails or is disconnected while a cluster is operation, a link failure occurs. When a link failure occurs the cluster units negotiate to select a new primary unit. Since the primary unit has not stopped operating, it participates in the negotiation. The link failure means that a new primary unit must be selected and the cluster unit with the link failure joins the cluster as a subordinate unit.

Just as for a device failover, the new primary unit sends gratuitous arp packets out all of its interfaces to inform attached switches to send traffic to it. Sessions then resume with the new primary unit.

If a subordinate unit experiences a device failure its status in the cluster does not change. However, in future negotiations a cluster unit with a link failure is unlikely to become the primary unit.

Session failover

If you enable session failover (also called session pickup) for the cluster, during cluster operation the primary unit informs the subordinate units of changes to the primary unit connection and state tables, keeping the subordinate units up-to-date with the traffic currently being processed by the cluster.

After a failover the new primary unit recognizes open sessions that were being handled by the cluster. The sessions continue to be processed by the new primary unit and are handled according to their last known state.

If you leave session pickup disabled, the cluster does not keep track of sessions and after a failover, active sessions have to be restarted or resumed.

Primary unit recovery

If a primary unit recovers after a device or link failure, it will operate as a subordinate unit, unless the `override` CLI keyword is enabled and its device priority is set higher than the unit priority of other cluster units (see HA override).

About active-active failover

HA failover in a cluster running in active-active mode is similar to active-passive failover described above. Active-active subordinate units are constantly waiting to negotiate to become primary units and, if session failover is enabled, continuously receive connection state information from the primary unit. If the primary unit fails, or one of the primary unit interfaces fails, the cluster units use the same mechanisms to detect the failure and to negotiate to select a new primary unit. If session failover is enabled, the new primary unit also maintains communication sessions through the cluster using the shared connection state table.

Active-active HA load balances sessions among all cluster units. For session failover, the cluster must maintain all of these sessions. To load balance sessions, the functioning cluster uses a load balancing schedule to distribute sessions to all cluster units. The shared connection state table tracks the communication sessions being processed by all cluster units (not just the primary unit). After a failover, the new primary unit uses the load balancing schedule to re-distribute all of the communication sessions recorded in the shared connection state table among all of the remaining cluster units. The connections continue to be processed by the cluster, but possibly by a different cluster unit, and are handled according to their last known state.

Device failover

The FGCP provides transparent device failover. Device failover is a basic requirement of any highly available system. Device failover means that if a device fails, a replacement device automatically takes the place of the failed device and continues operating in the same manner as the failed device.

In the case of FortiOS HA, the device is the primary unit. If the primary unit fails, device failover ensures that one of the subordinate units in the cluster automatically takes the place of the primary unit and can continue processing network traffic in the same way as the failed primary unit.

Device failover does not maintain communication sessions. After a device failover, communication sessions have to be restarted. To maintain communication sessions, you must enable session failover. See Session failover (session pick-up) on page 1496.

FortiGate HA device failover is supported by the HA heartbeat, virtual MAC addresses, configuration synchronization, route synchronization and IPsec VPN SA synchronization.

The HA heartbeat makes sure that the subordinate units detect a primary unit failure. If the primary unit fails to respond on time to HA heartbeat packets the subordinate units assume that the primary unit has failed and negotiate to select a new primary unit.

The new primary unit takes the place of the failed primary unit and continues functioning in the same way as the failed primary unit. For the new primary unit to continue functioning like the failed primary unit, the new primary unit must be able to reconnect to network devices and the new primary unit must have the same configuration as the failed primary unit.

FortiGate HA uses virtual MAC addresses to reconnect the new primary unit to network devices. The FGCP causes the new primary unit interfaces to acquire the same virtual MAC addresses as the failed primary unit. As a result, the new primary unit has the same network identity as the failed primary unit.

The new primary unit interfaces have different physical connections than the failed primary unit. Both the failed and the new primary unit interfaces are connected to the same switches, but the new primary unit interfaces are connected to different ports on these switches. To make sure that the switches send packets to the new primary unit, the new primary unit interfaces send gratuitous ARP packets to the connected switches. These gratuitous ARP packets notify the switches that the primary unit MAC and IP addresses are on different switch ports and cause the switches to send packets to the ports connected to the new primary unit. In this way, the new primary unit continues to receive packets that would otherwise have been sent to the failed primary unit.

Configuration synchronization means that the new primary unit always has the same configuration as the failed primary unit. As a result the new primary unit operates in exactly the same way as the failed primary unit. If configuration synchronization were not available the new primary unit may not process network traffic in the same way as the failed primary unit.

Kernel routing table synchronization synchronizes the primary unit kernel routing table to all subordinate units so that after a failover the new primary unit does not have to form a completely new routing table. IPsec VPN SA synchronization synchronizes IPsec VPN security associations (SAs) and other IPsec session data so that after a failover the new primary unit can resume IPsec tunnels without having to establish new SAs.

HA heartbeat and communication between cluster units

The HA heartbeat keeps cluster units communicating with each other. The heartbeat consists of hello packets that are sent at regular intervals by the heartbeat interface of all cluster units. These hello packets describe the state of the cluster unit and are used by other cluster units to keep all cluster units synchronized.

HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8890. The default time interval between HA heartbeats is 200 ms. The FGCP uses link-local IP4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

For best results, isolate the heartbeat devices from your user networks by connecting the heartbeat devices to a separate switch that is not connected to any network. If the cluster consists of two FortiGate units you can connect the heartbeat device interfaces directly using a crossover cable. Heartbeat packets contain sensitive

information about the cluster configuration. Heartbeat packets may also use a considerable amount of network bandwidth. For these reasons, it is preferable to isolate heartbeat packets from your user networks.

On startup, a FortiGate unit configured for HA operation broadcasts HA heartbeat hello packets from its HA heartbeat interface to find other FortiGate units configured to operate in HA mode. If two or more FortiGate units operating in HA mode connect with each other, they compare HA configurations (HA mode, HA password, and HA group ID). If the HA configurations match, the units negotiate to form a cluster.

While the cluster is operating, the HA heartbeat confirms that all cluster units are functioning normally. The heartbeat also reports the state of all cluster units, including the communication sessions that they are processing.

Heartbeat interfaces

A heartbeat interface is an Ethernet network interface in a cluster that is used by the FGCP for HA heartbeat communications between cluster units.

To change the HA heartbeat configuration go to **System > Config > HA** and select the *FortiGate interfaces* to use as HA heartbeat interfaces.

Do not use a switch port for the HA heartbeat traffic. This configuration is not supported.

From the CLI enter the following command to make port4 and port5 HA heartbeat interfaces and give both interfaces a heartbeat priority of 150:

```
config system ha
   set hbdev port4 150 port5 150
end
```

The following example shows how to change the default heartbeat interface configuration so that the port4 and port1 interfaces can be used for HA heartbeat communication and to give the port4 interface the highest heartbeat priority so that port4 is the preferred HA heartbeat interface.

```
config system ha
   set hbdev port4 100 port1 50
end
```

By default, for most FortiGate models two interfaces are configured to be heartbeat interfaces. You can change the heartbeat interface configuration as required. For example you can select additional or different heartbeat interfaces. You can also select only one heartbeat interface.

In addition to selecting the heartbeat interfaces, you also set the **Priority** for each heartbeat interface. In all cases, the heartbeat interface with the highest priority is used for all HA heartbeat communication. If the interface fails or becomes disconnected, the selected heartbeat interface that has the next highest priority handles all heartbeat communication.

If more than one heartbeat interface has the same priority, the heartbeat interface with the highest priority that is also highest in the heartbeat interface list is used for all HA heartbeat communication. If this interface fails or becomes disconnected, the selected heartbeat interface with the highest priority that is next highest in the list handles all heartbeat communication.

The default heartbeat interface configuration sets the priority of two heartbeat interfaces to 50. You can accept the default heartbeat interface configuration if one or both of the default heartbeat interfaces are connected. You can select different heartbeat interfaces, select more heartbeat interfaces and change heartbeat priorities according to your requirements.

For the HA cluster to function correctly, you must select at least one heartbeat interface and this interface of all of the cluster units must be connected together. If heartbeat communication is interrupted and cannot failover to a second heartbeat interface, the cluster units will not be able to communicate with each other and more than one cluster unit may become a primary unit. As a result the cluster stops functioning normally because multiple devices on the network may be operating as primary units with the same IP and MAC addresses creating a kind if split brain scenario.

The heartbeat interface priority range is 0 to 512. The default priority when you select a new heartbeat interface is 0. The higher the number the higher the priority.

In most cases you can maintain the default heartbeat interface configuration as long as you can connect the heartbeat interfaces together. Configuring HA heartbeat interfaces is the same for virtual clustering and for standard HA clustering.

You can enable heartbeat communications for physical interfaces, but not for VLAN subinterfaces, IPsec VPN interfaces, redundant interfaces, or for 802.3ad aggregate interfaces. You cannot select these types of interfaces in the heartbeat interface list.

Selecting more heartbeat interfaces increases reliability. If a heartbeat interface fails or is disconnected, the HA heartbeat fails over to the next heartbeat interface.

You can select up to 8 heartbeat interfaces. This limit only applies to FortiGate units with more than 8 physical interfaces.

HA heartbeat traffic can use a considerable amount of network bandwidth. If possible, enable HA heartbeat traffic on interfaces used only for HA heartbeat traffic or on interfaces connected to less busy networks.

Connecting HA heartbeat interfaces

For most FortiGate models if you do not change the heartbeat interface configuration, you can isolate the default heartbeat interfaces of all of the cluster units by connecting them all to the same switch. Use one switch per heartbeat interface. If the cluster consists of two units you can connect the heartbeat interfaces together using crossover cables.

HA heartbeat and data traffic are supported on the same cluster interface. In NAT/Route mode, if you decide to use heartbeat interfaces for processing network traffic or for a management connection, you can assign the interface any IP address. This IP address does not affect HA heartbeat traffic.

In Transparent mode, you can connect the heartbeat interface to your network and enable management access. You would then establish a management connection to the interface using the Transparent mode management IP address. This configuration does not affect HA heartbeat traffic.

Heartbeat packets and heartbeat interface selection

HA heartbeat hello packets are constantly sent by all of the enabled heartbeat interfaces. Using these hello packets, each cluster unit confirms that the other cluster units are still operating. The FGCP selects one of the heartbeat interfaces to be used for communication between the cluster units. The FGCP selects the heartbeat interface for heartbeat communication based on the linkfail states of the heartbeat interfaces, on the priority of the heartbeat interfaces, and on the interface index.

The FGCP checks the linkfail state of all heartbeat interfaces to determine which ones are connected. The FGCP selects one of these connected heartbeat interfaces to be the one used for heartbeat communication. The FGCP selects the connected heartbeat interface with the highest priority for heartbeat communication.

If more than one connected heartbeat interface has the highest priority the FGCP selects the heartbeat interface with the lowest interface index. The web-based manager lists the FortiGate unit interfaces in alphabetical order. This order corresponds to the interface index order with lowest index at the top and highest at the bottom. If more than one heartbeat interface has the highest priority, the FGCP selects the interface that is highest in the heartbeat interface list (or first in alphabetical order) for heartbeat communication.

If the interface that is processing heartbeat traffic fails or becomes disconnected, the FGCP uses the same criteria to select another heartbeat interface for heartbeat communication. If the original heartbeat interface is fixed or reconnected, the FGCP again selects this interface for heartbeat communication.

The HA heartbeat communicates cluster session information, synchronizes the cluster configuration, synchronizes the cluster kernel routing table, and reports individual cluster member status. The HA heartbeat constantly communicates HA status information to make sure that the cluster is operating properly.

Interface index and display order

The web-based manager and CLI display interface names in alphanumeric order. For example, the sort order for a FortiGate unit with 10 interfaces (named port1 through port10) places port10 at the bottom of the list:

- port1
- port2 through 9
- port10

However, interfaces are indexed in hash map order, rather than purely by alphabetic order or purely by interface number value comparisons. As a result, the list is sorted primarily alphabetical by interface name (for example, base1 is before port1), then secondarily by index numbers:

- port1
- port10
- port2 through port9

HA heartbeat interface IP addresses

The FGCP uses link-local IP4 addresses (RFC 3927) in the 169.254.0.x range for HA heartbeat interface IP addresses and for inter-VDOM link interface IP addresses. When a cluster initially starts up, the primary unit heartbeat interface IP address is 169.254.0.1. Subordinate units are assigned heartbeat interface IP addresses in the range 169.254.0.2 to 169.254.0.63. HA inter-VDOM link interfaces on the primary unit are assigned IP addresses 169.254.0.65 and 169.254.0.66.

The ninth line of the following CLI command output shows the HA heartbeat interface IP address of the primary unit.

```
get system ha status
   Model: 620
   Mode: a-p
   Group: 0
   Debug: 0
   ses_pickup: disable
   Master:150 head_office_upper FG600B3908600825 1
   Slave :150 head_office_lower FG600B3908600705 0
   number of vcluster: 1
   vcluster 1: work 169.254.0.1
   Master:0 FG600B3908600825
   Slave :1 FG600B3908600705
```

You can also use the `execute traceroute` command from the subordinate unit CLI to display HA heartbeat IP addresses and the HA inter-VDOM link IP addresses. For example, use `execute ha manage 1` to connect to the subordinate unit CLI and then enter the following command to trace the route to an IP address on your network:

```
execute traceroute 172.20.20.10
   traceroute to 172.20.20.10 (172.20.20.10), 32 hops max, 72 byte packets
       1 169.254.0.1 0 ms 0 ms 0 ms
       2 169.254.0.66 0 ms 0 ms 0 ms
       3 172.20.20.10 0 ms 0 ms 0 ms
```

Both HA heartbeat and data traffic are supported on the same FortiGate interface. All heartbeat communication takes place on a separate VDOM called vsys_ha. Heartbeat traffic uses a virtual interface called port_ha in the vsys_ha VDOM. Data and heartbeat traffic use the same physical interface, but they're logically separated into separate VDOMs.

Heartbeat packet Ethertypes

Normal IP packets are 802.3 packets that have an Ethernet type (Ethertype) field value of 0x0800. Ethertype values other than 0x0800 are understood as level2 frames rather than IP packets.

By default, HA heartbeat packets use the following Ethertypes:

- HA heartbeat packets for NAT/Route mode clusters use Ethertype 0x8890. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `ha-eth-type` option of the `config system ha` command.
- HA heartbeat packets for Transparent mode clusters use Ethertype 0x8891. These packets are used by cluster units to find other cluster units and to verify the status of other cluster units while the cluster is operating. You can change the Ethertype of these packets using the `hc-eth-type` option of the `config system ha` command.
- HA telnet sessions between cluster units over HA heartbeat links use Ethertype 0x8893. The telnet sessions are used to synchronize the cluster configurations. Telnet sessions are also used when an administrator uses the `execute ha manage` command to connect from one cluster unit CLI to another. You can change the Ethertype of these packets using the `l2ep-eth-type` option of the `config system ha` command.

Because heartbeat packets are recognized as level2 frames, the switches and routers on your heartbeat network that connect to heartbeat interfaces must be configured to allow them. If level2 frames are dropped by these network devices, heartbeat traffic will not be allowed between the cluster units.

Some third-party network equipment may use packets with these Ethertypes for other purposes. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8893, and 0x8891 to pass.

Alternatively, you can use the following CLI options to change the Ethertypes of the HA heartbeat packets:

```
config system ha
   set ha-eth-type <ha_ethertype_4-digit_hex
   set hc-eth-type <hc_ethertype_4-digit_ex>
   set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For example, use the following command to change the Ethertype of the HA heartbeat packets from 0x8890 to 0x8895 and to change the Ethertype of HA Telnet session packets from 0x8891 to 0x889f:

```
config system ha
   set ha-eth-type 8895
   set l2ep-eth-type 889f
end
```

Modifying heartbeat timing

In an HA cluster, if a cluster unit CPU becomes very busy, the cluster unit may not be able to send heartbeat packets on time. If heartbeat packets are not sent on time other units in the cluster may think that the cluster unit has failed and the cluster will experience a failover.

A cluster unit CPU may become very busy if the cluster is subject to a syn flood attack, if network traffic is very heavy, or for other similar reasons. You can use the following CLI commands to configure how the cluster times HA heartbeat packets:

```
config system ha
   set hb-interval <interval_integer>
   set hb-lost-threshold <threshold_integer>
   set helo-holddown <holddown_integer>
end
```

Changing the lost heartbeat threshold

The lost heartbeat threshold is the number of consecutive heartbeat packets that are not received from another cluster unit before assuming that the cluster unit has failed. The default value is 6, meaning that if the 6 heartbeat packets are not received from a cluster unit then that cluster unit is considered to have failed. The range is 1 to 60 packets.

If the primary unit does not receive a heartbeat packet from a subordinate unit before the heartbeat threshold expires, the primary unit assumes that the subordinate unit has failed.

If a subordinate unit does not receive a heartbeat packet from the primary unit before the heartbeat threshold expires, the subordinate unit assumes that the primary unit has failed. The subordinate unit then begins negotiating to become the new primary unit.

The lower the `hb-lost-threshold` the faster a cluster responds when a unit fails. However, sometimes heartbeat packets may not be sent because a cluster unit is very busy. This can lead to a false positive failure detection. To reduce these false positives you can increase the `hb-lost-threshold`.

Use the following CLI command to increase the lost heartbeat threshold to 12:

```
config system ha
   set hb-lost-threshold 12
end
```

Changing the heartbeat interval

The heartbeat interval is the time between sending HA heartbeat packets. The heartbeat interval range is 1 to 20 (100*ms). The heartbeat interval default is 2 (200 ms).

A heartbeat interval of 2 means the time between heartbeat packets is 200 ms. Changing the heartbeat interval to 5 changes the time between heartbeat packets to 500 ms (5 * 100ms = 500ms).

The HA heartbeat packets consume more bandwidth if the heartbeat interval is short. But if the heartbeat interval is very long, the cluster is not as sensitive to topology and other network changes.

Use the following CLI command to increase the heartbeat interval to 10:

```
config system ha
   set hb-interval 10
end
```

The heartbeat interval combines with the lost heartbeat threshold to set how long a cluster unit waits before assuming that another cluster unit has failed and is no longer sending heartbeat packets. By default, if a cluster unit does not receive a heartbeat packet from a cluster unit for 6 * 200 = 1200 milliseconds or 1.2 seconds the cluster unit assumes that the other cluster unit has failed.

You can increase both the heartbeat interval and the lost heartbeat threshold to reduce false positives. For example, increasing the heartbeat interval to 20 and the lost heartbeat threshold to 30 means a failure will be assumed if no heartbeat packets are received after 30 * 2000 milliseconds = 60,000 milliseconds, or 60 seconds.

Use the following CLI command to increase the heartbeat interval to 20 and the lost heartbeat threshold to 30:

```
config system ha
   set hb-lost-threshold 20
   set hb-interval 30
end
```

Changing the time to wait in the helo state

The hello state hold-down time is the number of seconds that a cluster unit waits before changing from hello state to work state. After a failure or when starting up, cluster units operate in the hello state to send and receive heartbeat packets so that all the cluster units can find each other and form a cluster. A cluster unit should change from the hello state to work state after it finds all of the other FortiGate units to form a cluster with. If for some reason all cluster units cannot find each other during the hello state then some cluster units may be joining the cluster after it has formed. This can cause disruptions to the cluster and affect how it operates.

One reason for a delay in all of the cluster units joining the cluster could be the cluster units are located at different sites of if for some other reason communication is delayed between the heartbeat interfaces.

If cluster units are joining your cluster after it has started up of if it takes a while for units to join the cluster you can increase the time that the cluster units wait in the helo state. The hello state hold-down time range is 5 to 300 seconds. The hello state hold-down time default is 20 seconds.

Use the following CLI command to increase the time to wait in the helo state to 1 minute (60 seconds):

```
config system ha
   set helo-holddown 60
end
```

Enabling or disabling HA heartbeat encryption and authentication

You can enable HA heartbeat encryption and authentication to encrypt and authenticate HA heartbeat packets. HA heartbeat packets should be encrypted and authenticated if the cluster interfaces that send HA heartbeat packets are also connected to your networks.

If HA heartbeat packets are not encrypted the cluster password and changes to the cluster configuration could be exposed and an attacker may be able to sniff HA packets to get cluster information. Enabling HA heartbeat message authentication prevents an attacker from creating false HA heartbeat messages. False HA heartbeat messages could affect the stability of the cluster.

HA heartbeat encryption and authentication are disabled by default. Enabling HA encryption and authentication could reduce cluster performance. Use the following CLI command to enable HA heartbeat encryption and authentication.

```
config system ha
```

```
    set authentication enable
    set encryption enable
end
```

HA authentication and encryption uses AES-128 for encryption and SHA1 for authentication.

Cluster virtual MAC addresses

When a cluster is operating, the FGCP assigns virtual MAC addresses to each primary unit interface. HA uses virtual MAC addresses so that if a failover occurs, the new primary unit interfaces will have the same virtual MAC addresses and IP addresses as the failed primary unit. As a result, most network equipment would identify the new primary unit as the exact same device as the failed primary unit.

If the MAC addresses changed after a failover, the network would take longer to recover because all attached network devices would have to learn the new MAC addresses before they could communicate with the cluster.

If a cluster is operating in NAT/Route mode, the FGCP assigns a different virtual MAC address to each primary unit interface. VLAN subinterfaces are assigned the same virtual MAC address as the physical interface that the VLAN subinterface is added to. Redundant interfaces or 802.3ad aggregate interfaces are assigned the virtual MAC address of the first interface in the redundant or aggregate list.

If a cluster is operating in Transparent mode, the FGCP assigns a virtual MAC address for the primary unit management IP address. Since you can connect to the management IP address from any interface, all of the FortiGate interfaces appear to have the same virtual MAC address.

A MAC address conflict can occur if two clusters are operating on the same network. See Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain on page 1469 for more information.

Subordinate unit MAC addresses do not change. You can verify this by connecting to the subordinate unit CLI and using the `get hardware interface nic` command to display the MAC addresses of each FortiGate interface.

The MAC address of a reserved management interface is not changed to a virtual MAC address. Instead the reserved management interface keeps its original MAC address.

When the new primary unit is selected after a failover, the primary unit sends gratuitous ARP packets to update the devices connected to the cluster interfaces (usually layer-2 switches) with the virtual MAC address. Gratuitous ARP packets configure connected network devices to associate the cluster virtual MAC addresses and cluster IP address with primary unit physical interfaces and with the layer-2 switch physical interfaces. This is sometimes called using gratuitous ARP packets (sometimes called GARP packets) to train the network. The gratuitous ARP packets sent from the primary unit are intended to make sure that the layer-2 switch forwarding databases (FDBs) are updated as quickly as possible.

Sending gratuitous ARP packets is not required for routers and hosts on the network because the new primary unit will have the same MAC and IP addresses as the failed primary unit. However, since the new primary unit interfaces are connected to different switch interfaces than the failed primary unit, many network switches will update their FDBs more quickly after a failover if the new primary unit sends gratuitous ARP packets.

Changing how the primary unit sends gratuitous ARP packets after a failover

When a failover occurs it is important that the devices connected to the primary unit update their FDBs as quickly as possible to reestablish traffic forwarding.

Depending on your network configuration, you may be able to change the number of gratuitous ARP packets and the time interval between ARP packets to reduce the cluster failover time.

You cannot disable sending gratuitous ARP packets, but you can use the following command to change the number of packets that are sent. For example, enter the following command to send 20 gratuitous ARP packets:

```
config system ha
   set arps 20
end
```

You can use this command to configure the primary unit to send from 1 to 60 ARP packets. Usually you would not change the default setting of 5. In some cases, however, you might want to reduce the number of gratuitous ARP packets. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending a higher number gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully, you could reduce the number of gratuitous ARP packets that are sent to reduce the amount of traffic produced after a failover.

If failover is taking longer that expected, you may be able to reduce the failover time by increasing the number gratuitous ARP packets sent.

You can also use the following command to change the time interval in seconds between gratuitous ARP packets. For example, enter the following command to change the time between ARP packets to 3 seconds:

```
config system ha
   set arps-interval 3
end
```

The time interval can be in the range of 1 to 20 seconds. The default is 8 seconds between gratuitous ARP packets. Normally you would not need to change the time interval. However, you could decrease the time to be able send more packets in less time if your cluster takes a long time to failover.

There may also be a number of reasons to set the interval higher. For example, if your cluster has a large number of VLAN interfaces and virtual domains and because gratuitous ARP packets are broadcast, sending gratuitous ARP packets may generate a lot of network traffic. As long as the cluster still fails over successfully you could increase the interval to reduce the amount of traffic produced after a failover.

For more information about gratuitous ARP packets see RFC 826 and RFC 3927.

Disabling gratuitous ARP packets after a failover

You can use the following command to turn off sending gratuitous ARP packets after a failover:

```
config system ha
   set gratuitous-arps disable
end
```

Sending gratuitous ARP packets is turned on by default.

In most cases you would want to send gratuitous ARP packets because its a reliable way for the cluster to notify the network to send traffic to the new primary unit. However, in some cases, sending gratuitous ARP packets may be less optimal. For example, if you have a cluster of FortiGate units in Transparent mode, after a failover the new primary unit will send gratuitous ARP packets to all of the addresses in its Forwarding Database (FDB). If the

FDB has a large number of addresses it may take extra time to send all the packets and the sudden burst of traffic could disrupt the network.

If you choose to disable sending gratuitous ARP packets you must first enable the `link-failed-signal` setting. The cluster must have some way of informing attached network devices that a failover has occurred.

For more information about the `link-failed-signal` setting, see Updating MAC forwarding tables when a link failover occurs on page 1489.

How the virtual MAC address is determined

The virtual MAC address is determined based on following formula:

```
00-09-0f-09-<group-id_hex>-(<vcluster_integer> + <idx>)
```

where

`<group-id_hex>` is the HA Group ID for the cluster converted to hexadecimal.The following table lists the virtual MAC address set for each group ID.

HA group ID in integer and hexadecimal format

Integer Group ID	Hexadecimal Group ID
0	00
1	01
2	02
3	03
4	04
…	…
10	0a
11	0b
…	…
63	3f
…	…
255	ff

`<vcluster_integer>` is 0 for virtual cluster 1 and 20 for virtual cluster 2. If virtual domains are not enabled, HA sets the virtual cluster to 1 and by default all interfaces are in the root virtual domain. Including virtual cluster and virtual domain factors in the virtual MAC address formula means that the same formula can be used whether or not virtual domains and virtual clustering is enabled.

<idx> is the index number of the interface. Interfaces are numbered from 0 to x (where x is the number of interfaces). Interfaces are numbered according to their has map order. See Interface index and display order on page 1460. The first interface has an index of 0. The second interface in the list has an index of 1 and so on.

Only the <idx> part of the virtual MAC address is different for each interface. The <vcluster_integer> would be different for different interfaces if multiple VDOMs have been added.

Between FortiOS releases interface indexing may change so the virtual MAC addresses assigned to individual FortiGate interfaces may also change.

Example virtual MAC addresses

An HA cluster with HA group ID unchanged (default=0) and virtual domains not enabled would have the following virtual MAC addresses for interfaces port1 to port12:

- port1 virtual MAC: 00-09-0f-09-00-00
- port10 virtual MAC: 00-09-0f-09-00-01
- port2 virtual MAC: 00-09-0f-09-00-02
- port3 virtual MAC: 00-09-0f-09-00-03
- port4 virtual MAC: 00-09-0f-09-00-04
- port5 virtual MAC: 00-09-0f-09-00-05
- port6 virtual MAC: 00-09-0f-09-00-06
- port7 virtual MAC: 00-09-0f-09-00-07
- port8 virtual MAC: 00-09-0f-09-00-08
- port9 virtual MAC: 00-09-0f-09-00-09
- port11 virtual MAC: 00-09-0f-09-00-0a
- port12 virtual MAC: 00-09-0f-09-00-0b

If the group ID is changed to 34 these virtual MAC addresses change to:

- port1 virtual MAC: 00-09-0f-09-22-00
- port3 virtual MAC: 00-09-0f-09-22-03
- port4 virtual MAC: 00-09-0f-09-22-04
- port5 virtual MAC: 00-09-0f-09-22-05
- port6 virtual MAC: 00-09-0f-09-22-06
- port7 virtual MAC: 00-09-0f-09-22-07
- port8 virtual MAC: 00-09-0f-09-22-08
- port9 virtual MAC: 00-09-0f-09-22-09
- port11 virtual MAC: 00-09-0f-09-22-0a
- port12 virtual MAC: 00-09-0f-09-22-0b
- port10 virtual MAC: 00-09-0f-09-22-01
- port2 virtual MAC: 00-09-0f-09-22-02

A cluster with virtual domains enabled where the HA group ID has been changed to 23, port5 and port 6 are in the root virtual domain (which is in virtual cluster1), and port7 and port8 are in the vdom_1 virtual domain (which is in virtual cluster 2) would have the following virtual MAC addresses:

- port5 interface virtual MAC: `00-09-0f-09-23-05`
- port6 interface virtual MAC: `00-09-0f-09-23-06`
- port7 interface virtual MAC: `00-09-0f-09-23-27`
- port8 interface virtual MAC: `00-09-0f-09-23-28`

Displaying the virtual MAC address

Every FortiGate unit physical interface has two MAC addresses: the current hardware address and the permanent hardware address. The permanent hardware address cannot be changed, it is the actual MAC address of the interface hardware. The current hardware address can be changed. The current hardware address is the address seen by the network. For a FortiGate unit not operating in HA, you can use the following command to change the current hardware address of the port1 interface:

```
config system interface
   edit port1
      set macaddr <mac_address>
   end
end
```

For an operating cluster, the current hardware address of each cluster unit interface is changed to the HA virtual MAC address by the FGCP. The `macaddr` option is not available for a functioning cluster. You cannot change an interface MAC address and you cannot view MAC addresses from the `system interface` CLI command.

You can use the `get hardware nic <interface_name_str>` command to display both MAC addresses for any FortiGate interface. This command displays hardware information for the specified interface. Depending on their hardware configuration, this command may display different information for different interfaces. You can use this command to display the current hardware address as `Current_HWaddr` and the permanent hardware address as `Permanent_HWaddr`. For some interfaces the current hardware address is displayed as `MAC`. The command displays a great deal of information about the interface so you may have to scroll the output to find the hardware addresses.

You can also use the `diagnose hardware deviceinfo nic <interface_str>` command to display both MAC addresses for any FortiGate interface.

Before HA configuration the current and permanent hardware addresses are the same. For example for one of the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
.
.
.
MAC: 02:09:0f:78:18:c9
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

During HA operation the current hardware address becomes the HA virtual MAC address, for example for the units in Cluster_1:

```
FGT60B3907503171 # get hardware nic internal
```

```
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 02:09:0f:78:18:c9
.
.
.
```

The following command output for Cluster_2 shows the same current hardware address for port1 as for the internal interface of Cluster_2, indicating a MAC address conflict.

```
FG300A2904500238 # get hardware nic port1
.
.
.
MAC: 00:09:0f:09:00:02
Permanent_HWaddr: 00:09:0F:85:40:FD
.
.
.
```

Diagnosing packet loss with two FortiGate HA clusters in the same broadcast domain

A network may experience packet loss when two FortiGate HA clusters have been deployed in the same broadcast domain. Deploying two HA clusters in the same broadcast domain can result in packet loss because of MAC address conflicts. The packet loss can be diagnosed by pinging from one cluster to the other or by pinging both of the clusters from a device within the broadcast domain. You can resolve the MAC address conflict by changing the HA Group ID configuration of the two clusters. The HA Group ID is sometimes also called the Cluster ID.

This section describes a topology that can result in packet loss, how to determine if packets are being lost, and how to correct the problem by changing the HA Group ID.

Packet loss on a network can also be caused by IP address conflicts. Finding and fixing IP address conflicts can be difficult. However, if you are experiencing packet loss and your network contains two FortiGate HA clusters you can use the information in this article to eliminate one possible source of packet loss.

Changing the HA group ID to avoid MAC address conflicts

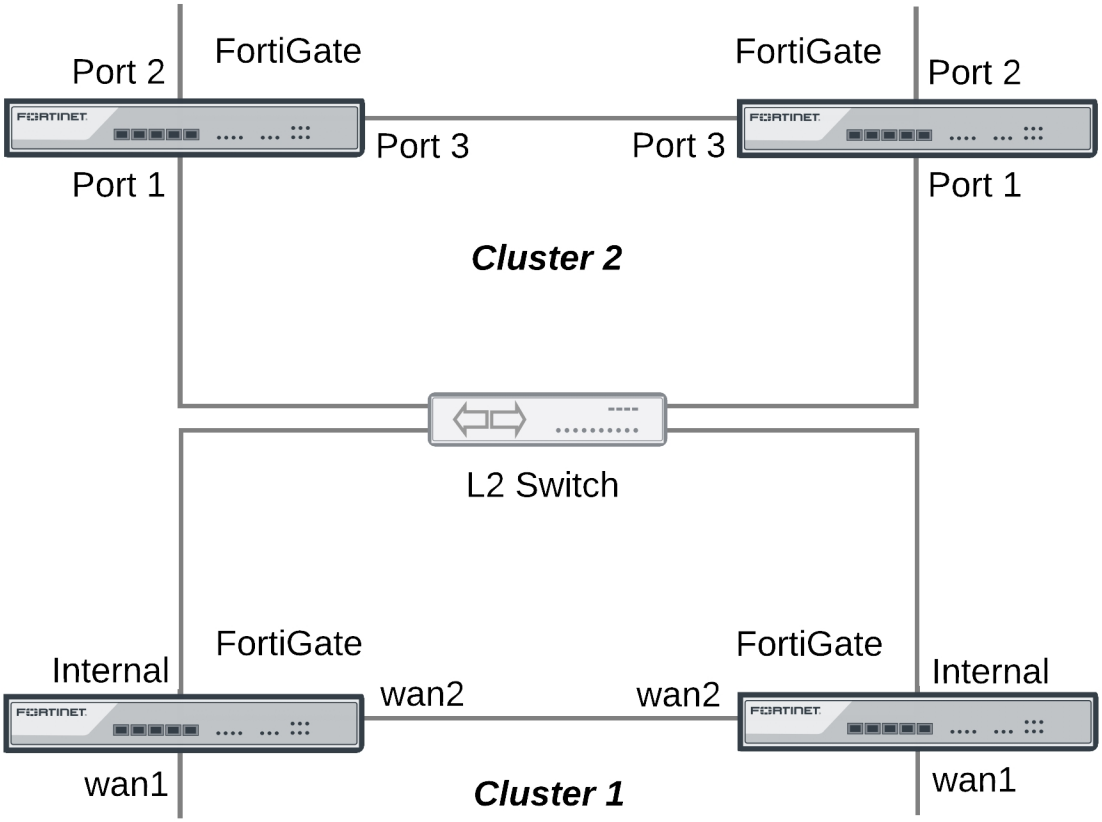
Change the Group ID to change the virtual MAC address of all cluster interfaces. You can change the Group ID from the FortiGate CLI using the following command:

```
config system ha
   set group-id <id_integer>
end
```

Example topology

The topology below shows two clusters. The Cluster_1 internal interfaces and the Cluster_2 port 1 interfaces are both connected to the same broadcast domain. In this topology the broadcast domain could be an internal network. Both clusters could also be connected to the Internet or to different networks.

Example HA topology with possible MAC address conflicts



Ping testing for packet loss

If the network is experiencing packet loss, it is possible that you will not notice a problem unless you are constantly pinging both HA clusters. During normal operation of the network you also might not notice packet loss because the loss rate may not be severe enough to timeout TCP sessions. Also many common types if TCP traffic, such as web browsing, may not be greatly affected by packet loss. However, packet loss can have a significant effect on real time protocols that deliver audio and video data.

To test for packet loss you can set up two constant ping sessions, one to each cluster. If packet loss is occurring the two ping sessions should show alternating replies and timeouts from each cluster.

Cluster_1	Cluster_2
reply	timeout
reply	timeout
reply	timeout
timeout	reply
timeout	reply
reply	timeout
reply	timeout
timeout	reply
timeout	reply
timeout	reply
timeout	reply

Viewing MAC address conflicts on attached switches

If two HA clusters with the same virtual MAC address are connected to the same broadcast domain (L2 switch or hub), the MAC address will conflict and bounce between the two clusters. This example Cisco switch MAC address table shows the MAC address flapping between different interfaces (1/0/1 and 1/0/4).

```
1 0009.0f09.0002 DYNAMIC Gi1/0/1
1 0009.0f09.0002 DYNAMIC Gi1/0/4
```

Synchronizing the configuration

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit.

The following settings are not synchronized between cluster units:

- HA override.
- HA device priority.
- The virtual cluster priority.
- The FortiGate unit host name.
- The HA priority setting for a ping server (or dead gateway detection) configuration.
- The system interface settings of the HA reserved management interface.
- The HA default route for the reserved management interface, set using the `ha-mgmt-interface-gateway` option of the `config system ha` command.

The primary unit synchronizes all other configuration settings, including the other HA configuration settings.

Disabling automatic configuration synchronization

In some cases you may want to use the following command to disable automatic synchronization of the primary unit configuration to all cluster units.

```
config system ha
   set sync-config disable
end
```

When this option is disabled the cluster no longer synchronizes configuration changes. If a device failure occurs, the new primary unit may not have the same configuration as the failed primary unit. As a result, the new primary unit may process sessions differently or may not function on the network in the same way.

In most cases you should not disable automatic configuration synchronization. However, if you have disabled this feature you can use the `execute ha synchronize` command to manually synchronize a subordinate unit's configuration to that of the primary unit.

You must enter `execute ha synchronize` commands from the subordinate unit that you want to synchronize with the primary unit. Use the `execute ha manage` command to access a subordinate unit CLI.

For example, to access the first subordinate unit and force a synchronization at any time, even if automatic synchronization is disabled enter:

```
execute ha manage 0
execute ha synchronize start
```

You can use the following command to stop a synchronization that is in progress.

```
execute ha synchronize stop
```

Incremental synchronization

When you log into the cluster web-based manager or CLI to make configuration changes, you are actually logging into the primary unit. All of your configuration changes are first made to the primary unit. Incremental synchronization then immediately synchronizes these changes to all of the subordinate units.

When you log into a subordinate unit CLI (for example using `execute ha manage`) all of the configuration changes that you make to the subordinate unit are also immediately synchronized to all cluster units, including the primary unit, using the same process.

Incremental synchronization also synchronizes other dynamic configuration information such as the DHCP server address lease database, routing table updates, IPsec SAs, MAC address tables, and so on. SeeAn introduction to the FGCP on page 1270 for more information about DHCP server address lease synchronization and Synchronizing kernel routing tables on page 1480 for information about routing table updates.

Whenever a change is made to a cluster unit configuration, incremental synchronization sends the same configuration change to all other cluster units over the HA heartbeat link. An HA synchronization process running on the each cluster unit receives the configuration change and applies it to the cluster unit. The HA synchronization process makes the configuration change by entering a CLI command that appears to be entered by the administrator who made the configuration change in the first place.

Synchronization takes place silently, and no log messages are recorded about the synchronization activity. However, log messages can be recorded by the cluster units when the synchronization process enters CLI commands. You can see these log messages on the subordinate units if you enable event logging and set the minimum severity level to **Information** and then check the event log messages written by the cluster units when you make a configuration change.

You can also see these log messages on the primary unit if you make configuration changes from a subordinate unit.

Periodic synchronization

Incremental synchronization makes sure that as an administrator makes configuration changes, the configurations of all cluster units remain the same. However, a number of factors could cause one or more cluster units to go out of sync with the primary unit. For example, if you add a new unit to a functioning cluster, the configuration of this new unit will not match the configuration of the other cluster units. Its not practical to use incremental synchronization to change the configuration of the new unit.

Periodic synchronization is a mechanism that looks for synchronization problems and fixes them. Every minute the cluster compares the configuration file checksum of the primary unit with the configuration file checksums of each of the subordinate units. If all subordinate unit checksums are the same as the primary unit checksum, all cluster units are considered synchronized.

If one or more of the subordinate unit checksums is not the same as the primary unit checksum, the subordinate unit configuration is considered out of sync with the primary unit. The checksum of the out of sync subordinate unit is checked again every 15 seconds. This re-checking occurs in case the configurations are out of sync because an incremental configuration sequence has not completed. If the checksums do not match after 5 checks the subordinate unit that is out of sync retrieves the configuration from the primary unit. The subordinate unit then reloads its configuration and resumes operating as a subordinate unit with the same configuration as the primary unit.

The configuration of the subordinate unit is reset in this way because when a subordinate unit configuration gets out of sync with the primary unit configuration there is no efficient way to determine what the configuration differences are and to correct them. Resetting the subordinate unit configuration becomes the most efficient way to resynchronize the subordinate unit.

Synchronization requires that all cluster units run the same FortiOS firmware build. If some cluster units are running different firmware builds, then unstable cluster operation may occur and the cluster units may not be able to synchronize correctly.

Re-installing the firmware build running on the primary unit forces the primary unit to upgrade all cluster units to the same firmware build.

Console messages when configuration synchronization succeeds

When a cluster first forms, or when a new unit is added to a cluster as a subordinate unit, the following messages appear on the CLI console to indicate that the unit joined the cluster and had its configuring synchronized with the primary unit.

```
slave's configuration is not in sync with master's, sequence:0
slave's configuration is not in sync with master's, sequence:1
   slave's configuration is not in sync with master's, sequence:2
   slave's configuration is not in sync with master's, sequence:3
   slave's configuration is not in sync with master's, sequence:4
   slave starts to sync with master
logout all admin users
slave succeeded to sync with master
```

Console messages when configuration synchronization fails

If you connect to the console of a subordinate unit that is out of synchronization with the primary unit, messages similar to the following are displayed.

```
slave is not in sync with master, sequence:0. (type 0x3)
slave is not in sync with master, sequence:1. (type 0x3)
slave is not in sync with master, sequence:2. (type 0x3)
slave is not in sync with master, sequence:3. (type 0x3)
slave is not in sync with master, sequence:4. (type 0x3)
global compared not matched
```

If synchronization problems occur the console message sequence may be repeated over and over again. The messages all include a type value (in the example `type 0x3`). The type value can help Fortinet Support diagnose the synchronization problem.

HA out of sync object messages and the configuration objects that they reference

Out of Sync Message	Configuration Object
HA_SYNC_SETTING_CONFIGURATION = 0x03	/data/config

Comparing checksums of cluster units

You can use the `diagnose sys ha showcsum` command to compare the configuration checksums of all cluster units. The output of this command shows checksums labelled `global` and `all` as well as checksums for each of the VDOMs including the `root` VDOM. The `get system ha-nonsync-csum` command can be used to display similar information; however, this command is intended to be used by FortiManager.

The primary unit and subordinate unit checksums should be the same. If they are not you can use the `execute ha synchronize` command to force a synchronization.

The following command output is for the primary unit of a cluster that does not have multiple VDOMs enabled:

```
diagnose sys ha showcsum
is_manage_master()=1, is_root_master()=1
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
```

```
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following command output is for a subordinate unit of the same cluster:

```
diagnose sys ha showcsum
is_manage_master()=0, is_root_master()=0
debugzone
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5

checksum
global: a0 7f a7 ff ac 00 d5 b6 82 37 cc 13 3e 0b 9b 77
root: 43 72 47 68 7b da 81 17 c8 f5 10 dd fd 6b e9 57
all: c5 90 ed 22 24 3e 96 06 44 35 b6 63 7c 84 88 d5
```

The following example shows using this command for the primary unit of a cluster with multiple VDOMs. Two VDOMs have been added named `test` and `Eng_vdm`.

From the primary unit:

```
config global
   sys ha showcsum
   is_manage_master()=1, is_root_master()=1
   debugzone
   global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
   test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
   root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
   Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
   all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

   checksum
   global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
   test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
   root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
   Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
   all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

From the subordinate unit:

```
config global
   diagnose sys ha showcsum
   is_manage_master()=0, is_root_master()=0
   debugzone
   global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
   test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
   root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
   Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
   all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53

   checksum
   global: 65 75 88 97 2d 58 1b bf 38 d3 3d 52 5b 0e 30 a9
   test: a5 16 34 8c 7a 46 d6 a4 1e 1f c8 64 ec 1b 53 fe
   root: 3c 12 45 98 69 f2 d8 08 24 cf 02 ea 71 57 a7 01
   Eng_vdm: 64 51 7c 58 97 79 b1 b3 b3 ed 5c ec cd 07 74 09
```

```
all: 30 68 77 82 a1 5d 13 99 d1 42 a3 2f 9f b9 15 53
```

How to diagnose HA out of sync messages

This section describes how to use the commands `diagnose sys ha showcsum` and `diagnose debug` to diagnose the cause of HA out of sync messages.

If HA synchronization is not successful, use the following procedures on each cluster unit to find the cause.

To determine why HA synchronization does not occur

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following commands to enable debugging and display HA out of sync messages.

   ```
   diagnose debug enable
   diagnose debug console timestamp enable
   diagnose debug application hatalk -1
   diagnose debug application hasync -1
   ```

   Collect the console output and compare the out of sync messages with the information on page 203.
3. Enter the following commands to turn off debugging.

   ```
   diagnose debug disable
   diagnose debug reset
   ```

To determine what part of the configuration is causing the problem

If the previous procedure displays messages that include sync object 0x30 (for example, `HA_SYNC_SETTING_CONFIGURATION = 0x03`) there is a synchronization problem with the configuration. Use the following steps to determine the part of the configuration that is causing the problem.

If your cluster consists of two cluster units, use this procedure to capture the configuration checksums for each unit. If your cluster consists of more that two cluster units, repeat this procedure for all cluster units that returned messages that include 0x30 sync object messages.

1. Connect to each cluster unit CLI by connected to the console port.
2. Enter the following command to turn on terminal capture

   ```
   diagnose debug enable
   ```
3. Enter the following command to stop HA synchronization.

   ```
   execute ha sync stop
   ```
4. Enter the following command to display configuration checksums.

   ```
   diagnose sys ha showcsum 1
   ```
5. Copy the output to a text file.
6. Repeat for all affected units.
7. Compare the text file from the primary unit with the text file from each cluster unit to find the checksums that do not match.

   You can use a diff function to compare text files.
8. Repeat steps 4 to 7 for each checksum level:

   ```
   diagnose sys ha showcsum 2
   diagnose sys ha showcsum 3
   diagnose sys ha showcsum 4
   diagnose sys ha showcsum 5
   ```

```
diagnose sys ha showcsum 6
diagnose sys ha showcsum 7
diagnose sys ha showcsum 8
```

9. When the non-matching checksum is found, attempt to drill down further. This is possible for objects that have sub-components.

   For example you can enter the following commands:

   ```
   diagnose sys ha showcsum system.global
   diagnose sys ha showcsum system.interface
   ```

   Generally it is the first non-matching checksum in one of the levels that is the cause of the synchronization problem.

10. Attempt to can remove/change the part of the configuration that is causing the problem. You can do this by making configuration changes from the primary unit or subordinate unit CLI.
11. Enter the following commands to start HA configuration and stop debugging:

    ```
    execute ha sync start
    diagnose debug disable
    diagnose debug reset
    ```

Recalculating the checksums to resolve out of sync messages

Sometimes an error can occur when checksums are being calculated by the cluster. As a result of this calculation error the CLI console could display out of sync error messages even though the cluster is otherwise operating normally. You can also sometimes see checksum calculation errors in `diagnose sys ha showcsum` command output when the checksums listed in the `debugzone` output don't match the checksums in the `checksum` part of the output.

One solution to this problem could be to re-calculate the checksums. The re-calculated checksums should match and the out of sync error messages should stop appearing.

You can use the following command to re-calculate HA checksums:

```
diagnose sys ha csum-recalculate [<vdom-name> | global]
```

Just entering the command without options recalculates all checksums. You can specify a VDOM name to just recalculate the checksums for that VDOM. You can also enter `global` to recalculate the global checksum.

Synchronizing kernel routing tables

In a functioning cluster, the primary unit keeps all subordinate unit kernel routing tables (also called the forwarding information base FIB) up to date and synchronized with the primary unit. After a failover, because of these routing table updates the new primary unit does not have to populate its kernel routing table before being able to route traffic. This gives the new primary unit time to rebuild its regular routing table after a failover.

Use the following command to view the regular routing table. This table contains all of the configured routes and routes acquired from dynamic routing protocols and so on. This routing table is not synchronized. On subordinate units this command will not produce the same output as on the primary unit.

```
get router info routing-table
```

Use the following command to view the kernel routing table (FIB). This is the list of resolved routes actually being used by the FortiOS kernel. The output of this command should be the same on the primary unit and the subordinate units.

```
get router info kernel
```

This section describes how clusters handle dynamic routing failover and also describes how to use CLI commands to control the timing of routing table updates of the subordinate unit routing tables from the primary unit.

Controlling how the FGCP synchronizes kernel routing table updates

You can use the following commands to control some of the timing settings that the FGCP uses when synchronizing routing updates from the primary unit to subordinate units and maintaining routes on the primary unit after a failover.

```
config system ha
   set route-hold <hold_integer>
   set route-ttl <ttl_integer>
   set route-wait <wait_integer>
end
```

Change how long routes stay in a cluster unit routing table

Change the `route-ttl` time to control how long routes remain in a cluster unit routing table. The time to live range is 5 to 3600 seconds. The default time to live is 10 seconds.

The time to live controls how long routes remain active in a cluster unit routing table after the cluster unit becomes a primary unit. To maintain communication sessions after a cluster unit becomes a primary unit, routes remain active in the routing table for the route time to live while the new primary unit acquires new routes.

By default, `route-ttl` is set to 10 which may mean that only a few routes will remain in the routing table after a failover. Normally keeping `route-ttl` to 10 or reducing the value to 5 is acceptable because acquiring new routes usually occurs very quickly, especially if graceful restart is enabled, so only a minor delay is caused by acquiring new routes.

If the primary unit needs to acquire a very large number of routes, or if for other reasons, there is a delay in acquiring all routes, the primary unit may not be able to maintain all communication sessions.

You can increase the route time to live if you find that communication sessions are lost after a failover so that the primary unit can use synchronized routes that are already in the routing table, instead of waiting to acquire new routes.

Change the time between routing updates

Change the `route-hold` time to change the time that the primary unit waits between sending routing table updates to subordinate units. The route hold range is 0 to 3600 seconds. The default route hold time is 10 seconds.

To avoid flooding routing table updates to subordinate units, set `route-hold` to a relatively long time to prevent subsequent updates from occurring too quickly. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Increasing the time between updates means that this data exchange will not have to happen so often.

The `route-hold` time should be coordinated with the `route-wait` time.

Change the time the primary unit waits after receiving a routing update

Change the `route-wait` time to change how long the primary unit waits after receiving routing updates before sending the updates to the subordinate units. For quick routing table updates to occur, set route-wait to a

relatively short time so that the primary unit does not hold routing table changes for too long before updating the subordinate units.

The `route-wait` range is 0 to 3600 seconds. The default `route-wait` is 0 seconds.

Normally, because the `route-wait` time is 0 seconds the primary unit sends routing table updates to the subordinate units every time its routing table changes.

Once a routing table update is sent, the primary unit waits the `route-hold` time before sending the next update.

Usually routing table updates are periodic and sporadic. Subordinate units should receive these changes as soon as possible so `route-wait` is set to 0 seconds. `route-hold` can be set to a relatively long time because normally the next route update would not occur for a while.

In some cases, routing table updates can occur in bursts. A large burst of routing table updates can occur if a router or a link on a network fails or changes. When a burst of routing table updates occurs, there is a potential that the primary unit could flood the subordinate units with routing table updates. Flooding routing table updates can affect cluster performance if a great deal of routing information is synchronized between cluster units. Setting `route-wait` to a longer time reduces the frequency of additional updates are and prevents flooding of routing table updates from occurring.

Configuring graceful restart for dynamic routing failover

When an HA failover occurs, neighbor routers will detect that the cluster has failed and remove it from the network until the routing topology stabilizes. During that time the routers may stop sending IP packets to the cluster and communication sessions that would normally be processed by the cluster may time out or be dropped. Also the new primary unit will not receive routing updates and so will not be able to build and maintain its routing database.

You can solve this problem by configuring graceful restart for the dynamic routing protocols that you are using. This section describes configuring graceful restart for OSPF and BGP.

To support graceful restart you should make sure the new primary unit keeps its synchronized routing data long enough to acquire new routing data. You should also increase the HA route time to live, route wait, and route hold values to 60 using the following CLI command:

```
config system ha
   set route-ttl 60
   set route-wait 60
   set route-hold 60
end
```

Graceful OSPF restart

You can configure graceful restart (also called nonstop forwarding (NSF)) as described in RFC3623 (Graceful OSPF Restart) to solve the problem of dynamic routing failover. If graceful restart is enabled on neighbor routers, they will keep sending packets to the cluster following the HA failover instead of removing it from the network. The neighboring routers assume that the cluster is experiencing a graceful restart.

After the failover, the new primary unit can continue to process communication sessions using the synchronized routing data received from the failed primary unit before the failover. This gives the new primary unit time to update its routing table after the failover.

You can use the following commands to enable graceful restart or NSF on Cisco routers:

```
router ospf 1
```

```
    log-adjacency-changes
    nsf ietf helper strict-lsa-checking
```

If the cluster is running OSPF, use the following command to enable graceful restart for OSFP:

```
config router ospf
   set restart-mode graceful-restart
end
```

Graceful BGP restart

If the cluster is running BGP only the primary unit keeps BGP peering connections. When a failover occurs, the BGP peering needs to be reestablished. This will happen if you enable BGP graceful restart which causes the adjacent routers to keep the routes active while the BGP peering is restarted by the new primary unit.

> Enabling BGP graceful restart causes the FortiGate's BGP process to restart which can temporarily disrupt traffic through the cluster. So normally you should wait for a quiet time or a maintenance period to enable BGP graceful restart.

Use the following command to enable graceful restart for BGP and set some graceful restart options.

```
config router bgp
   set graceful-restart enable
   set graceful-restart-time 120
   set graceful-stalepath-time 360
   set graceful-update-delay 120
end
```

Notifing BGP neighbors when graceful restart is enabled

You can add BGP neighbors and configure the cluster unit to notify these neighbors that it supports graceful restart.

```
config router bgp
   config neighbor
      edit <neighbor_address_Ipv4>
         set capability-graceful-restart enable
      end
end
```

Bidirectional Forwarding Detection (BFD) enabled BGP graceful restart

You can add a BFD enabled BGP neighbor as a static BFD neighbor using the following command. This example shows how to add a BFD neighbor with IP address 172.20.121.23 that is on the network connected to port4:

```
config router bfd
   config neighbor
      edit 172.20.121.23
         set port4
      end
   end
```

The FGCP supports graceful restart of BFD enabled BGP neighbors. The `config router bfd` command is needed as the BGP auto-start timer is 5 seconds. After HA failover, BGP on the new primary unit has to wait for 5 seconds to connect to its neighbors, and then register BFD requests after establishing the connections. With static BFD neighbors, BFD requests and sessions can be created as soon as possible after the failover. The new command `get router info bfd requests` shows the BFD peer requests.

A BFD session created for a static BFD neighbor/peer request will initialize its state as "INIT" instead of "DOWN" and its detection time `asbfd-required-min-rx * bfd-detect-mult` milliseconds.

When a BFD control packet with nonzero your_discr is received, if no session can be found to match the your_discr, instead of discarding the packet, other fields in the packet, such as addressing information, are used to choose one session that was just initialized, with zero as its remote discriminator.

When a BFD session in the up state receives a control packet with zero as your_discr and down as the state, the session will change its state into down but will not notify this down event to BGP and/or other registered clients.

Synchronizing IPsec VPN SAs

The FGCP synchronizes IPsec security associations (SAs) between cluster members so that if a failover occurs, the cluster can resume IPsec sessions without having to establish new SAs. The result is improved failover performance because IPsec sessions are not interrupted to establish new SAs. Also, establishing a large number of SAs can reduce cluster performance.

The FGCP implements slightly different synchronization mechanisms for IKEv1 and IKEv2.

Synchronizing SAs for IKEv1

When an SA is synchronized to the subordinate units. the sequence number is set to the maximum sequence number. After a failover, all inbound traffic that connects with the new primary unit and uses the SA will be accepted without needing to re-key. However, first outbound packet to use the SA causes the sequence number to overflow and so causes the new primary unit to re-key the SA.

Please note the following:

- The cluster synchronizes all IPsec SAs.
- IPsec SAs are not synchronized until the IKE process has finished synchronizing the ISAKMP SAs. This is required in for dialup tunnels since it is the synchronizing of the ISAKMP SA that creates the dialup tunnel.
- A dialup interface is created as soon as the phase1 is complete. This ensures that the when HA synchronizes phase1 information the dialup name is included.
- If the IKE process re-starts for any reason it deletes any dialup tunnels that exist. This forces the peer to re-key them.
- IPsec SA deletion happens immediately. Routes associated with a dialup tunnel that is being deleted are cleaned up synchronously as part of the delete, rather than waiting for the SA hard-expiry.
- The FGCP does not sync the IPsec tunnel MTU from the primary unit to the subordinate units. This means that after HA failover if the first packet received by the FortiGate unit arrives after the HA route has been deleted and before the new route is added and the packet is larger than the default MTU of 1024 then the FortiGate unit sends back an ICMP fragmentation required. However, as soon as routing is re-established then the MTU will be corrected and traffic will flow.

Synchronizing SAs for IKEv2

Due to the way the IKEv2 protocol is designed the FGCP cannot use exactly the same solution that is used for synchronizing IKEv1 SAs, though it is similar.

For IKEv2, like IKEv1, the FGCP synchronizes IKE and ISAKMP SAs from the primary unit to the subordinate units. However, for IKEv2 the FGCP cannot actually use this IKE SA to send/receive IKE traffic because IKEv2 includes a sequence number in every IKE message and thus it would require synchronizing every message to the subordinate units to keep the sequence numbers on the subordinate units up to date.

Instead, the FGCP synchronizes IKEv2 Message IDs. This Message ID Sync allows IKEv2 to re-negotiate send and receive message ID counters after a failover. By doing this, the established IKE SA can remain up, instead of re-negotiating.

The `diagnose vpn ike stats` command shows statistics for the number of HA messages sent/received for IKEv2. The output of this command includes a number of fields prefixed with `ha` that contain high availably related-data. For example:

```
.
.
.
ha.resync: 0
ha.vike.sync: 0
ha.conn.sync: 0
ha.sync.tx: 1
ha.sync.rx: 0
ha.sync.rx.len.bad: 0
.
.
.
```

Link failover (port monitoring or interface monitoring)

Link failover means that if a monitored interface fails, the cluster reorganizes to reestablish a link to the network that the monitored interface was connected to and to continue operating with minimal or no disruption of network traffic.

You configure monitored interfaces (also called interface monitoring or port monitoring) by selecting the interfaces to monitor as part of the cluster HA configuration.

You can monitor up to 64 interfaces.

The interfaces that you can monitor appear on the port monitor list. You can monitor all FortiGate interfaces including redundant interfaces and 802.3ad aggregate interfaces.

You cannot monitor the following types of interfaces (you cannot select the interfaces on the port monitor list):

- FortiGate interfaces that contain an internal switch.
- VLAN subinterfaces.
- IPsec VPN interfaces.
- Individual physical interfaces that have been added to a redundant or 802.3ad aggregate interface.
- FortiGate-5000 series backplane interfaces that have not been configured as network interfaces.

If you are configuring a virtual cluster you can create a different port monitor configuration for each virtual cluster. Usually for each virtual cluster you would monitor the interfaces that have been added to the virtual domains in each virtual cluster.

Wait until after the cluster is up and running to enable interface monitoring. You do not need to configure interface monitoring to get a cluster up and running and interface monitoring will cause failovers if for some reason during initial setup a monitored interface has become disconnected. You can always enable interface monitoring once you have verified that the cluster is connected and operating properly.

You should only monitor interfaces that are connected to networks, because a failover may occur if you monitor an unconnected interface.

To enable interface monitoring - web-based manager

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster web-based manager.
2. Go to **System > Config > HA** and edit the primary unit (**Role** is **MASTER**).
3. Select the **Port Monitor** check boxes for the **port1** and **port2** interfaces and select **OK**.
   The configuration change is synchronized to all cluster units.

To enable interface monitoring - CLI

Use the following steps to monitor the port1 and port2 interfaces of a cluster.

1. Connect to the cluster CLI.
2. Enter the following command to enable interface monitoring for port1 and port2.

```
configure system ha
   set monitor port1 port2
end
```

The following example shows how to enable monitoring for the external, internal, and DMZ interfaces.

```
config system ha
   set monitor external internal dmz
end
```

With interface monitoring enabled, during cluster operation, the cluster monitors each cluster unit to determine if the monitored interfaces are operating and connected. Each cluster unit can detect a failure of its network interface hardware. Cluster units can also detect if its network interfaces are disconnected from the switch they should be connected to.

Cluster units cannot determine if the switch that its interfaces are connected to is still connected to the network. However, you can use remote IP monitoring to make sure that the cluster unit can connect to downstream network devices. See Remote link failover on page 1491.

Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link between a network and the primary unit fails, to maintain communication with this network, the cluster must select a different primary unit; one that is still connected to the network. Unless another link failure has occurred, the new primary unit will have an active link to the network and will be able to maintain communication with it.

To support link failover, each cluster unit stores link state information for all monitored cluster units in a link state database. All cluster units keep this link state database up to date by sharing link state information with the other cluster units. If one of the monitored interfaces on one of the cluster units becomes disconnected or fails, this information is immediately shared with all cluster units.

If a monitored interface on the primary unit fails

If a monitored interface on the primary unit fails, the cluster renegotiates to select a new primary unit using the process described in An introduction to the FGCP on page 1270. Because the cluster unit with the failed monitored interface has the lowest monitor priority, a different cluster unit becomes the primary unit. The new primary unit should have fewer link failures.

After the failover, the cluster resumes and maintains communication sessions in the same way as for a device failure. See Device failover on page 1456.

If a monitored interface on a subordinate unit fails

If a monitored interface on a subordinate unit fails, this information is shared with all cluster units. The cluster does not renegotiate. The subordinate unit with the failed monitored interface continues to function in the cluster.

In an active-passive cluster after a subordinate unit link failover, the subordinate unit continues to function normally as a subordinate unit in the cluster.

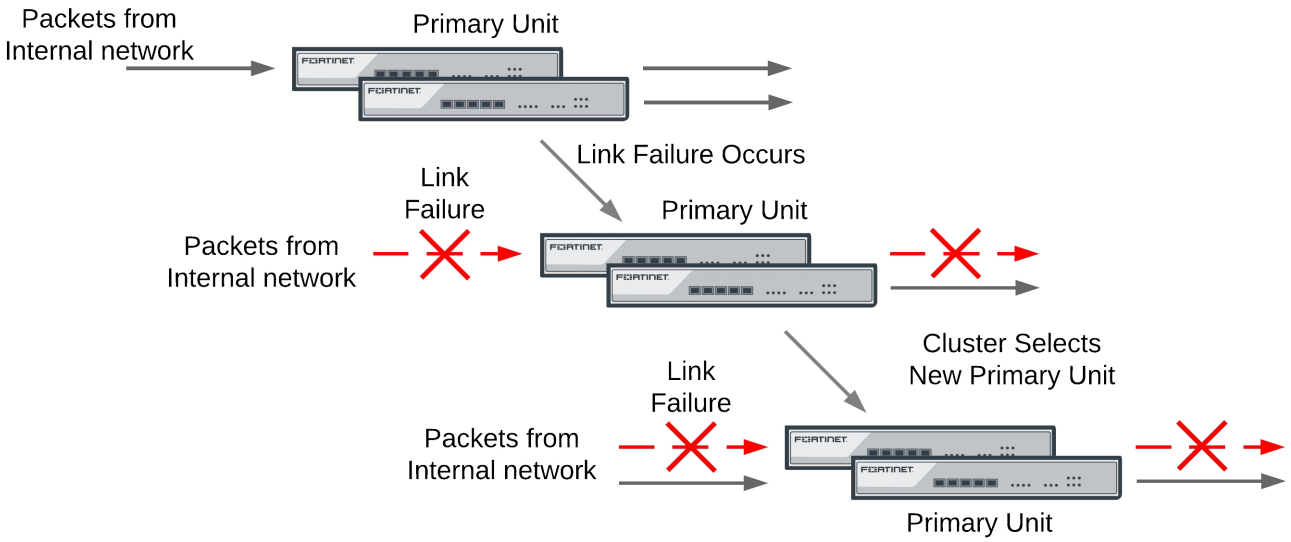
In an active-active cluster after a subordinate unit link failure:

- The subordinate unit with the failed monitored interface can continue processing connections between functioning interfaces. However, the primary unit stops sending sessions to a subordinate unit that use any failed monitored interfaces on the subordinate unit.
- If session pickup is enabled, all sessions being processed by the subordinate unit failed interface that can be failed over are failed over to other cluster units. Sessions that cannot be failed over are lost and have to be restarted.
- If session pickup is not enabled all sessions being processed by the subordinate unit failed interface are lost.

How link failover maintains traffic flow

Monitoring an interface means that the interface is connected to a high priority network. As a high priority network, the cluster should maintain traffic flow to and from the network, even if a link failure occurs. Because the primary unit receives all traffic processed by the cluster, a cluster can only process traffic from a network if the primary unit can connect to it. So, if the link that the primary unit has to a high priority network fails, to maintain traffic flow to and from this network, the cluster must select a different primary unit. This new primary unit should have an active link to the high priority network.

A link failure causes a cluster to select a new primary unit



If a monitored interface on the primary unit fails, the cluster renegotiates and selects the cluster unit with the highest monitor priority to become the new primary unit. The cluster unit with the highest monitor priority is the cluster unit with the most monitored interfaces connected to networks.

After a link failover, the primary unit processes all traffic and all subordinate units, even the cluster unit with the link failure, share session and link status. In addition all configuration changes, routes, and IPsec SAs are synchronized to the cluster unit with the link failure.

In an active-active cluster, the primary unit load balances traffic to all the units in the cluster. The cluster unit with the link failure can process connections between its functioning interfaces (for, example if the cluster has connections to an internal, external, and DMZ network, the cluster unit with the link failure can still process connections between the external and DMZ networks).

Recovery after a link failover and controlling primary unit selection (controlling falling back to the prior primary unit)

If you find and correct the problem that caused a link failure (for example, re-connect a disconnected network cable) the cluster updates its link state database and re-negotiates to select a primary unit.

What happens next depends on how the cluster configuration affects primary unit selection:

- The former primary unit will once again become the primary unit (falling back to becoming the primary unit)
- The primary unit will not change.

As described in An introduction to the FGCP on page 1270, when the link is restored, if no options are configured to control primary unit selection and the cluster age difference is less than 300 seconds the former primary unit will once again become the primary unit. If the age differences are greater than 300 seconds then a new primary unit is not selected. Since you have no control on the age difference the outcome can be unpredictable. This is not a problem in cases where its not important which unit becomes the primary unit.

Preventing a primary unit change after a failed link is restored

Some organizations will not want the cluster to change primary units when the link is restored. Instead they would rather wait to restore the primary unit during a maintenance window. This functionality is not directly supported, but you can experiment with changing some primary unit selection settings. For example, in most cases it should work to enable override on all cluster units and make sure their priorities are the same. This should mean that the primary unit should not change after a failed link is restored.

Then, when you want to restore the original primary unit during a maintenance window you can just set its Device Priority higher. After it becomes the primary unit you can reset all device priorities to the same value. Alternatively during a maintenance window you could reboot the current primary unit and any subordinate units except the one that you want to become the primary unit.

If the `override` CLI keyword is enabled on one or more cluster units and the device priority of a cluster unit is set higher than the others, when the link failure is repaired and the cluster unit with the highest device priority will always become the primary unit.

Testing link failover

You can test link failure by disconnecting the network cable from a monitored interface of a cluster unit. If you disconnect a cable from a primary unit monitored interface the cluster should renegotiate and select one of the other cluster units as the primary unit. You can also verify that traffic received by the disconnected interface continues to be processed by the cluster after the failover.

If you disconnect a cable from a subordinate unit interface the cluster will not renegotiate.

Updating MAC forwarding tables when a link failover occurs

When a FortiGate HA cluster is operating and a monitored interface fails on the primary unit, the primary unit usually becomes a subordinate unit and another cluster unit becomes the primary unit. After a link failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables (also called arp tables) of the switches connected to the cluster. This is normal link failover operation.

Even when gratuitous ARP packets are sent, some switches may not be able to detect that the primary unit has become a subordinate unit and will keep sending packets to the former primary unit. This can occur if the switch does not detect the failure and does not clear its MAC forwarding table.

You have another option available to make sure the switch detects the failover and clears its MAC forwarding tables. You can use the following command to cause a cluster unit with a monitored interface link failure to briefly shut down all of its interfaces (except the heartbeat interfaces) after the failover occurs:

```
config system ha
   set link-failed-signal enable
end
```

Usually this means each interface of the former primary unit is shut down for about a second. When this happens the switch should be able to detect this failure and clear its MAC forwarding tables of the MAC addresses of the former primary unit and pickup the MAC addresses of the new primary unit. Each interface will shut down for a

second but the entire process usually takes a few seconds. The more interfaces the FortiGate unit has, the longer it will take.

Normally, the new primary unit also sends gratuitous ARP packets that also help the switch update its MAC forwarding tables to connect to the new primary unit. If `link-failed-signal` is enabled, sending gratuitous ARP packets is optional and can be disabled if you don't need it or if its causing problems. See Disabling gratuitous ARP packets after a failover on page 1465.

Multiple link failures

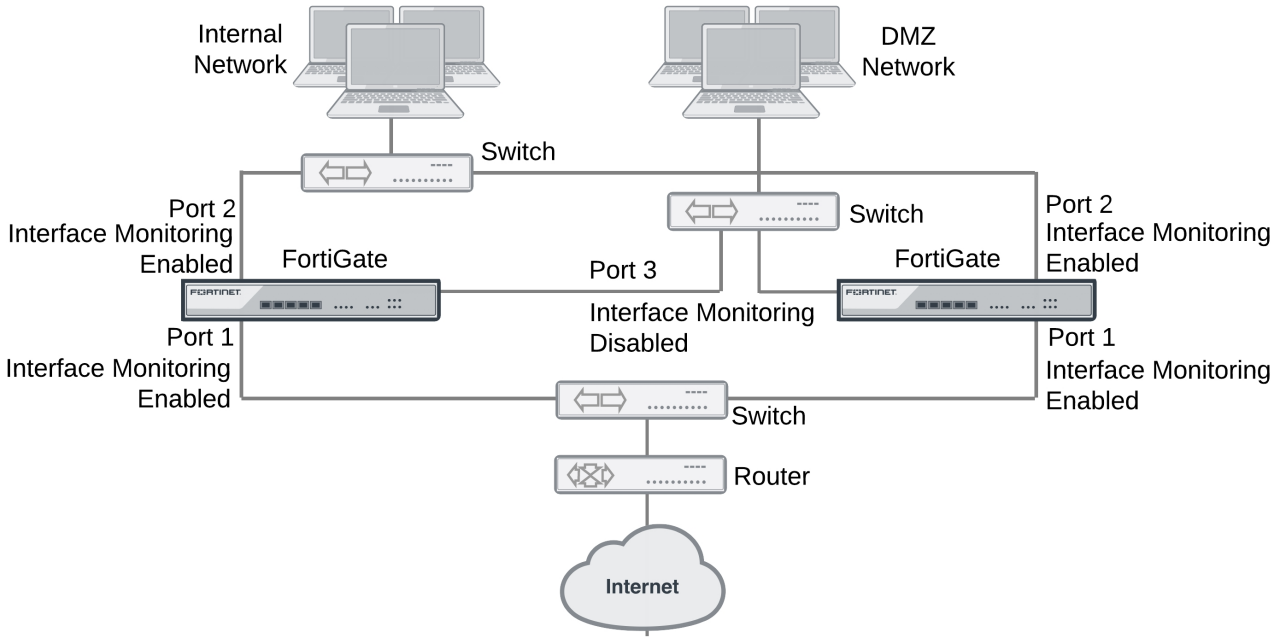
Every time a monitored interface fails, the cluster repeats the processes described above. If multiple monitored interfaces fail on more than one cluster unit, the cluster continues to negotiate to select a primary unit that can provide the most network connections.

Example link failover scenarios

For the following examples, assume a cluster configuration consisting of two FortiGate units (FGT_1 and FGT_2) connected to three networks: internal using port2, external using port1, and DMZ using port3. In the HA configuration, the device priority of FGT_1 is set higher than the unit priority of FGT_2.

The cluster processes traffic flowing between the internal and external networks, between the internal and DMZ networks, and between the external and DMZ networks. If there are no link failures, FGT1 becomes the primary unit because it has the highest device priority.

Sample link failover scenario topology



Example the port1 link on FGT_1 fails

If the port1 link on FGT_1 fails, FGT_2 becomes primary unit because it has fewer interfaces with a link failure. If the cluster is operating in active-active mode, the cluster load balances traffic between the internal network (port2) and the DMZ network (port3). Traffic between the Internet (port1) and the internal network (port2) and between the Internet (port1) and the DMZ network (port3) is processed by the primary unit only.

Example port2 on FGT_1 and port1 on FGT_2 fail

If port2 on FGT_1 and port1 on FGT_2 fail, then FGT_1 becomes the primary unit. After both of these link failures, both cluster units have the same monitor priority. So the cluster unit with the highest device priority (FGT_1) becomes the primary unit.

Only traffic between the Internet (port1) and DMZ (port3) networks can pass through the cluster and the traffic is handled by the primary unit only. No load balancing will occur if the cluster is operating in active-active mode.

Subsecond failover

On FortiGate models 395xB and 3x40B HA link failover supports subsecond failover (that is a failover time of less than one second). Subsecond failover is available for interfaces that can issue a link failure system call when the interface goes down. When an interface experiences a link failure and sends the link failure system call, the FGCP receives the system call and initiates a link failover.

For interfaces that do not support subsecond failover, port monitoring regularly polls the connection status of monitored interfaces. When a check finds that an interface has gone down, port monitoring causes a link failover. Subsecond failover results in a link failure being detected sooner because the system doesn't have to wait for the next poll to find out about the failure.

Subsecond failover can accelerate HA failover to reduce the link failover time to less than one second under ideal conditions. Actual failover performance may be vary depending on traffic patterns and network configuration. For example, some network devices may respond slowly to an HA failover.

No configuration changes are required to support subsecond failover. However, for best subsecond failover results, the recommended heartbeat interval is 100ms and the recommended lost heartbeat threshold is 5 (see Modifying heartbeat timing on page 1462).

```
config system ha
   set hb-lost-threshold 5
   set hb-interval 1
end
```

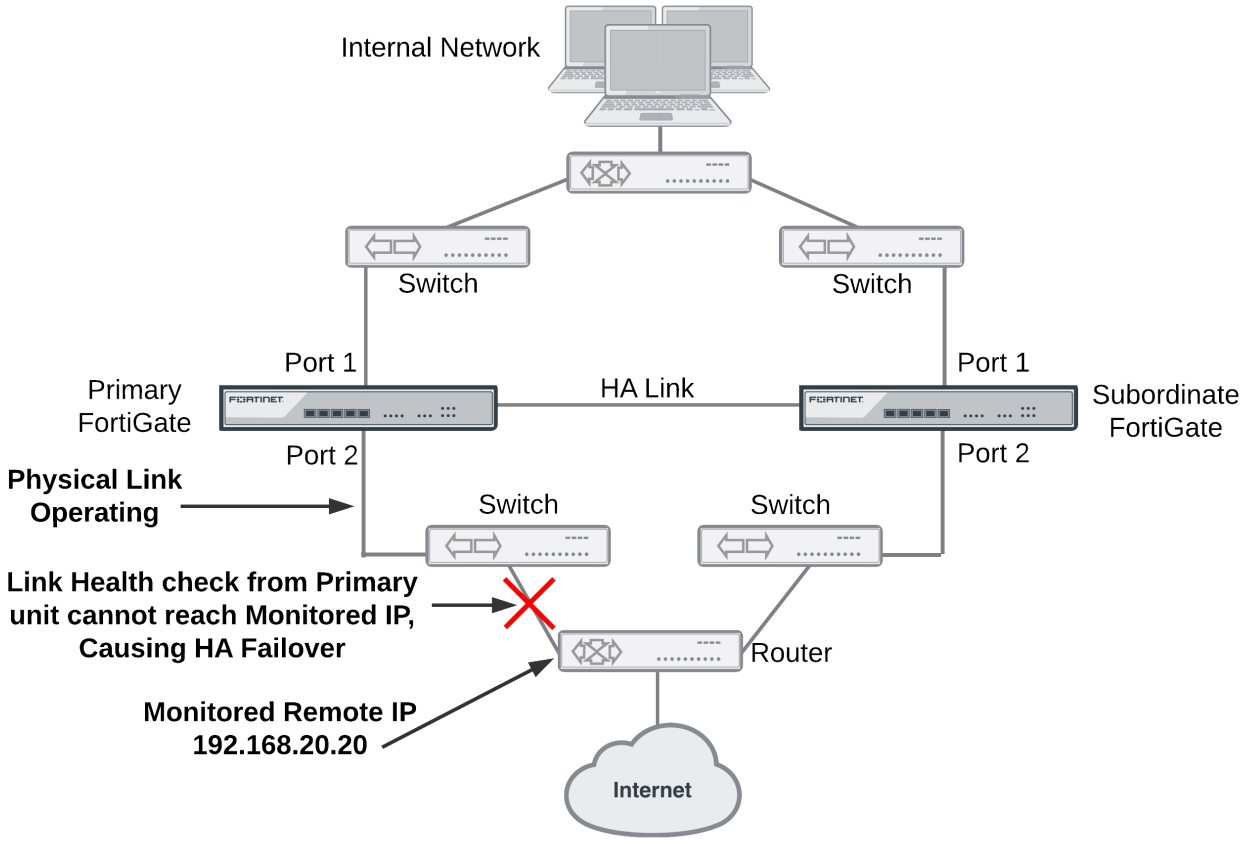
For information about how to reduce failover times, see Failover performance on page 1506.

Remote link failover

Remote link failover (also called remote IP monitoring) is similar to HA port monitoring and link health monitoring (also known as dead gateway detection). Port monitoring causes a cluster to failover if a monitored primary unit interface fails or is disconnected. Remote IP monitoring uses link health monitors configured for FortiGate interfaces on the primary unit to test connectivity with IP addresses of network devices. Usually these would be IP addresses of network devices not directly connected to the cluster. For example, a downstream router. Remote IP monitoring causes a failover if one or more of these remote IP addresses does not respond to link health checking.

By being able to detect failures in network equipment not directly connected to the cluster, remote IP monitoring can be useful in a number of ways depending on your network configuration. For example, in a full mesh HA configuration, with remote IP monitoring, the cluster can detect failures in network equipment that is not directly connected to the cluster but that would interrupt traffic processed by the cluster if the equipment failed.

Example HA remote IP monitoring topology



In the simplified example topology shown above, the switch connected directly to the primary unit is operating normally but the link on the other side of the switches fails. As a result traffic can no longer flow between the primary unit and the Internet.

To detect this failure you can create a link health monitor for port2 that causes the primary unit to test connectivity to 192.168.20.20. If the health monitor cannot connect to 192.268.20.20 the cluster to fails over and the subordinate unit becomes the new primary unit. After the failover, the health check monitor on the new primary unit can connect to 192.168.20.20 so the failover maintains connectivity between the internal network and the Internet through the cluster.

To configure remote IP monitoring

1. Enter the following commands to configure HA remote monitoring for the example topology.
   - Enter the `pingserver-monitor-interface` keyword to enable HA remote IP monitoring on port2.
   - Leave the `pingserver-failover-threshold` set to the default value of 5. This means a failover occurs if the link health monitor doesn't get a response after 5 attempts.

- Enter the `pingserver-flip-timeout` keyword to set the flip timeout to 120 minutes. After a failover, if HA remote IP monitoring on the new primary unit also causes a failover, the flip timeout prevents the failover from occurring until the timer runs out. Setting the `pingserver-flip-timeout` to 120 means that remote IP monitoring can only cause a failover every 120 minutes. This flip timeout is required to prevent repeating failovers if remote IP monitoring causes a failover from all cluster units because none of the cluster units can connect to the monitored IP addresses.

```
config system ha
   set pingserver-monitor-interface port2
   set pingserver-failover-threshold 5
   set pingserver-flip-timeout 120
end
```

2. Enter the following commands to add a link health monitor for the port2 interface and to set HA remote IP monitoring priority for this link health monitor.
   - Enter the `detectserver` keyword to set the health monitor server IP address to 192.168.20.20.
   - Leave the `ha-priority` keyword set to the default value of 1. You only need to change this priority if you change the HA `pingserver-failover-threshold`. The `ha-priority` setting is not synchronized among cluster units.

The `ha-priority` setting is not synchronized among cluster units. So if you want to change the `ha-priority` setting you must change it separately on each cluster unit. Otherwise it will remain set to the default value of 1.

   - Use the `interval` keyword to set the time between link health checks and use the `failtime` keyword to set the number of times that a health check can fail before a failure is detected (the failover threshold). The following example reduces the failover threshold to 2 but keeps the health check interval at the default value of 5.

```
config system link-monitor
   edit ha-link-monitor
      set server 192.168.20.20
      set srcintf port2
      set ha-priority 1
      set interval 5
      set failtime 2
   end
```

You can also do this from the web-based manager by going to **Router > Static > Settings > Link Health Monitor**, selecting **Create New** and set **Interface** to port2, **Probe Type** to Ping, **Server** to 192.168.20.20, **Probe Interval** to 5, **Failure Threshold** to 2 and **HA Priority** to 1.

Adding HA remote IP monitoring to multiple interfaces

You can enable HA remote IP monitoring on multiple interfaces by adding more interface names to the `pingserver-monitor-interface` keyword. If your FortiGate configuration includes VLAN interfaces, aggregate interfaces and other interface types, you can add the names of these interfaces to the `pingserver-monitor-interface` keyword to configure HA remote IP monitoring for these interfaces.

For example, enable remote IP monitoring for interfaces named port2, port20, and vlan_234:

```
config system ha
   set pingserver-monitor-interface port2 port20 vlan_234
```

```
    set pingserver-failover-threshold 10
    set pingserver-flip-timeout 120
end
```

Then configure health monitors for each of these interfaces. In the following example, default values are accepted for all settings other than the server IP address.

```
config system link-monitor
    edit port2
        set srcintf port2
        set server 192.168.20.20
    next
    edit port20
        set srcintf port20
        set server 192.168.20.30
    next
    edit vlan_234
        set srcintf vlan_234
        set server 172.20.12.10
    end
```

Changing the link monitor failover threshold

If you have multiple link monitors you may want a failover to occur only if more than one of them fails.

For example, you may have 3 link monitors configured on three interfaces but only want a failover to occur if two of the link monitors fail. To do this you must set the HA priorities of the link monitors and the HA `pingserver-failover-threshold` so that the priority of one link monitor is less than the failover threshold but the added priorities of two link monitors is equal to or greater than the failover threshold. Failover occurs when the HA priority of all failed link monitors reaches or exceeds the threshold.

For example, set the failover threshold to 10 and monitor three interfaces:

```
config system ha
    set pingserver-monitor-interface port2 port20 vlan_234
    set pingserver-failover-threshold 10
    set pingserver-flip-timeout 120
end
```

Then set the HA priority of link monitor server to 5.

The HA Priority (`ha-priority`) setting is not synchronized among cluster units. In the following example, you must set the HA priority to 5 by logging into each cluster unit.

```
config system link-monitor
    edit port2
        set server 192.168.20.20
        set ha-priority 5
    next
    edit port20
        set server 192.168.20.30
        set ha-priority 5
    next
    edit vlan_234
        set server 172.20.12.10
        set ha-priority 5
    end
```

If only one of the link monitors fails, the total link monitor HA priority will be 5, which is lower than the failover threshold so a failover will not occur. If a second link monitor fails, the total link monitor HA priority of 10 will equal the failover threshold, causing a failover.

By adding multiple link monitors and setting the HA priorities for each, you can fine tune remote IP monitoring. For example, if it is more important to maintain connections to some networks you can set the HA priorities higher for these link monitors. And if it is less important to maintain connections to other networks you can set the HA priorities lower for these link monitors. You can also adjust the failover threshold so that if the cluster cannot connect to one or two high priority IP addresses a failover occurs. But a failover will not occur if the cluster cannot connect to one or two low priority IP addresses.

Monitoring multiple IP addresses from one interface

You can add multiple IP addresses to a single link monitor to use HA remote IP monitoring to monitor more than one IP address from a single interface. If you add multiple IP addresses, the health checking will be with all of the addresses at the same time. The link monitor only fails when no responses are received from all of the addresses.

```
config system link-monitor
   edit port2
      set server 192.168.20.20 192.168.20.30 172.20.12.10
   end
```

Flip timeout

The HA remote IP monitoring configuration also involves setting a flip timeout. The flip timeout is required to reduce the frequency of failovers if, after a failover, HA remote IP monitoring on the new primary unit also causes a failover. This can happen if the new primary unit cannot connect to one or more of the monitored remote IP addresses. The result could be that until you fix the network problem that blocks connections to the remote IP addresses, the cluster will experience repeated failovers. You can control how often the failovers occur by setting the flip timeout. The flip timeout stops HA remote IP monitoring from causing a failover until the primary unit has been operating for the duration of the flip timeout.

If you set the flip timeout to a relatively high number of minutes you can find and repair the network problem that prevented the cluster from connecting to the remote IP address without the cluster experiencing very many failovers. Even if it takes a while to detect the problem, repeated failovers at relatively long time intervals do not usually disrupt network traffic.

Use the following command to set the flip timeout to 3 hours (360 minutes):

```
config system ha
   set pingserver-flip-timeout 360
end
```

Detecting HA remote IP monitoring failovers

Just as with any HA failover, you can detect HA remote IP monitoring failovers by using SNMP to monitor for HA traps. You can also use alert email to receive notifications of HA status changes and monitor log messages for HA failover log messages. In addition, FortiGate units send the critical log message `Ping Server is down` when a ping server fails. The log message includes the name of the interface that the ping server has been added to.

Session failover (session pick-up)

Session failover means that a cluster maintains active network TCP and IPsec VPN sessions (including NAT sessions) after a device or link failover. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover multicast, or SSL VPN sessions.

FortiGate HA does not support session failover by default. To enable session failover go to **System > Config > HA** and select **Enable Session Pick-up**.

From the CLI enter:

```
config system ha
   set session-pickup enable
end
```

To support session failover, when **Enable Session Pick-up** is selected, the FGCP maintains an HA session table for most TCP communication sessions being processed by the cluster and synchronizes this session table with all cluster units. If a cluster unit fails, the HA session table information is available to the remaining cluster units and these cluster units use this session table to resume most of the TCP sessions that were being processed by the failed cluster unit without interruption.

If session pickup is enabled, you can use the following command to also enable UDP and ICMP session failover:

```
config system ha
   set session-pickup-connectionless enable
end
```

You must enable session pickup for session failover protection. If you do not require session failover protection, leaving session pickup disabled may reduce CPU usage and reduce HA heartbeat network bandwidth usage.

If session pickup is not selected

If **Enable Session Pick-up** is not selected, the FGCP does not maintain an HA session table and most TCP sessions do not resume after a failover. After a device or link failover all sessions are briefly interrupted and must be re-established at the application level after the cluster renegotiates.

Many protocols can successfully restart sessions with little, if any, loss of data. For example, after a failover, users browsing the web can just refresh their browsers to resume browsing. Since most HTTP sessions are very short, in most cases they will not even notice an interruption unless they are downloading large files. Users downloading a large file may have to restart their download after a failover.

Other protocols may experience data loss and some protocols may require sessions to be manually restarted. For example, a user downloading files with FTP may have to either restart downloads or restart their FTP client.

Some sessions may resume after a failover whether or not enable session pick-up is selected:

- UDP, ICMP, multicast and broadcast packet session failover on page 1500
- FortiOS Carrier GTP session failover on page 1500
- Active-active HA subordinate units sessions can resume after a failover on page 1501

Improving session synchronization performance

Two HA configuration options are available to reduce the performance impact of enabling session pickup. They include reducing the number of sessions that are synchronized by adding a session pickup delay and using more FortiGate interfaces for session synchronization.

Reducing the number of sessions that are synchronized

Enable the `session-pickup-delay` CLI option to reduce the number of sessions that are synchronized by synchronizing sessions only if they remain active for more than 30 seconds. Enabling this option could greatly reduce the number of sessions that are synchronized if a cluster typically processes very many short duration sessions, which is typical of most HTTP traffic for example.

Use the following command to enable a 30 second session pickup delay:

```
config system ha
   set session-pickup-delay enable
end
```

Enabling session pickup delay means that if a failover occurs more sessions may not be resumed after a failover. In most cases short duration sessions can be restarted with only a minor traffic interruption. However, if you notice too many sessions not resuming after a failover you might want to disable this setting.

Using multiple FortiGate interfaces for session synchronization

Using the `session-sync-dev` option you can select one or more FortiGate interfaces to use for synchronizing sessions as required for session pickup. Normally session synchronization occurs over the HA heartbeat link. Using this HA option means only the selected interfaces are used for session synchronization and not the HA heartbeat link. If you select more than one interface, session synchronization traffic is load balanced among the selected interfaces.

Moving session synchronization from the HA heartbeat interface reduces the bandwidth required for HA heartbeat traffic and may improve the efficiency and performance of the cluster, especially if the cluster is synchronizing a large number of sessions. Load balancing session synchronization among multiple interfaces can further improve performance and efficiency if the cluster is synchronizing a large number of sessions.

Use the following command to perform cluster session synchronization using the port10 and port12 interfaces.

```
config system ha
   set session-sync-dev port10 port12
end
```

Session synchronization packets use Ethertype 0x8892. The interfaces to use for session synchronization must be connected together either directly using the appropriate cable (possible if there are only two units in the cluster) or using switches. If one of the interfaces becomes disconnected the cluster uses the remaining interfaces for session synchronization. If all of the session synchronization interfaces become disconnected, session synchronization reverts back to using the HA heartbeat link. All session synchronization traffic is between the primary unit and each subordinate unit.

Since large amounts of session synchronization traffic can increase network congestion, it is recommended that you keep this traffic off of your network by using dedicated connections for it.

Synchronizing GTP sessions to support GTP tunnel failover

FortiOS Carrier GPRS Tunneling Protocol (GTP) sessions are not normally synchronized by the FGCP, even if you enable session pickup. You can provide GTP session synchronization by using the `session-sync-dev` command to select one or two session sync interfaces. You must also connect these interfaces together either with direct connections or using switches.

You can also use the command, `diagnose firewall gtp hash-stat` to display GTP hash stat separately.

Session failover not supported for all sessions

Most of the features applied to sessions by FortiGate security profile functionality require the FortiGate unit to maintain very large amounts of internal state information for each session. The FGCP does not synchronize internal state information for the following security profile features, so the following types of sessions will not resume after a failover:

- Virus scanning of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, CIFS, and NNTP sessions,
- Web filtering and FortiGuard Web Filtering of HTTP and HTTPS sessions,
- Spam filtering of IMAP, IMAPS, POP3, POP3S, SMTP, and SMTPS sessions,
- DLP scanning of IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, SIP, SIMPLE, and SCCP sessions,
- DLP archiving of HTTP, HTTPS, FTP, IMAP, IMAPS, POP3, SMTP, SMTPS, IM, NNTP, AIM, ICQ, MSN, Yahoo! IM, SIP, SIMPLE, and SCCP signal control sessions,

Active-active clusters can resume some of these sessions after a failover. See Active-active HA subordinate units sessions can resume after a failover on page 1501 for details.

If you use these features to protect most of the sessions that your cluster processes, enabling session failover may not actually provide significant session failover protection.

TCP sessions that are not being processed by these security profile features resume after a failover even if these sessions are accepted by security policies with security profile options configured. Only TCP sessions that are actually being processed by these security profile features do not resume after a failover. For example:

- TCP sessions that are not virus scanned, web filtered, spam filtered, content archived, or are not SIP, SIMPLE, or SCCP signal traffic resume after a failover, even if they are accepted by a security policy with security profile options enabled. For example, SNMP TCP sessions resume after a failover because FortiOS does not apply any security profile options to SNMP sessions.
- TCP sessions for a protocol for which security profile features have not been enabled resume after a failover even if they are accepted by a security policy with security profile features enabled. For example, if you have not enabled any antivirus or content archiving settings for FTP, FTP sessions resume after a failover.

The following security profile features do not affect TCP session failover:

- IPS does not affect session failover. Sessions being scanned by IPS resume after a failover. After a failover; however, IPS can only perform packet-based inspection of resumed sessions; reducing the number of vulnerabilities that IPS can detect. This limitation only applies to in-progress resumed sessions.
- Application control does not affect session failover. Sessions that are being monitored by application control resume after a failover.
- Logging enabled form security profile features does not affect session failover. security profile logging writes log messages for security profile events; such as when a virus is found by antivirus scanning, when Web Filtering blocks a URL, and so on. Logging does not enable features that would prevent sessions from being failed over, logging just reports on the activities of enabled features.

If more than one security profile feature is applied to a TCP session, that session will not resume after a failover as long as one of the security profile features prevents session failover. For example:

- Sessions being scanned by IPS and also being virus scanned do not resume after a failover.
- Sessions that are being monitored by application control and that are being DLP archived or virus scanned will not resume after a failover.

IPv6, NAT64, and NAT66 session failover

The FGCP supports IPv6, NAT64, and NAT66 session failover, if session pickup is enabled, these sessions are synchronized between cluster members and after an HA failover the sessions will resume with only minimal interruption.

SIP session failover

The FGCP supports SIP session failover (also called stateful failover) for active-passive HA. To support SIP session failover, create a standard HA configuration and select **Enable Session Pick-up** option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in-progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA a failover occurs. But in most cases the call setup should be able to continue after the failover.

Explicit web proxy, WCCP, and WAN optimization session failover

Similar to security profile sessions, the explicit web proxy, WCCP and WAN optimization features all require the FortiGate unit to maintain very large amounts of internal state information for each session. This information is not maintained and these sessions do not resume after a failover.

SSL offloading and HTTP multiplexing session failover

SSL offloading and HTTP multiplexing are both enabled from firewall virtual IPs and firewall load balancing. Similar to the features applied by security profile, SSL offloading and HTTP multiplexing requires the FortiGate unit to maintain very large amounts of internal state information for each session. Sessions accepted by security policies containing virtual IPs or virtual servers with SSL offloading or HTTP multiplexing enabled do not resume after a failover.

IPsec VPN session failover

Session failover is supported for all IPsec VPN tunnels. To support IPsec VPN tunnel failover, when an IPsec VPN tunnel starts, the FGCP distributes the SA and related IPsec VPN tunnel data to all cluster units.

SSL VPN session failover and SSL VPN authentication failover

Session failover is not supported for SSL VPN tunnels. However, authentication failover is supported for the communication between the SSL VPN client and the FortiGate unit. This means that after a failover, SSL VPN clients can re-establish the SSL VPN session between the SSL VPN client and the FortiGate unit without having to authenticate again.

However, all sessions inside the SSL VPN tunnel that were running before the failover are stopped and have to be restarted. For example, file transfers that were in progress would have to be restarted. As well, any communication sessions with resources behind the FortiGate unit that are started by an SSL VPN session have to be restarted.

To support SSL VPN cookie failover, when an SSL VPN session starts, the FGCP distributes the cookie created to identify the SSL VPN session to all cluster units.

PPTP and L2TP VPN sessions

PPTP and L2TP VPNs are supported in HA mode. For a cluster you can configure PPTP and L2TP settings and you can also add security policies to allow PPTP and L2TP pass through. However, the FGCP does not provide session failover for PPTP or L2TP. After a failover, all active PPTP and L2TP sessions are lost and must be restarted.

UDP, ICMP, multicast and broadcast packet session failover

By default, even with session pickup enabled, the FGCP does not maintain a session table for UDP, ICMP, multicast, or broadcast packets. So the cluster does not specifically support failover of these packets.

Some UDP traffic can continue to flow through the cluster after a failover. This can happen if, after the failover, a UDP packet that is part of an already established communication stream matches a security policy. Then a new session will be created and traffic will flow. So after a short interruption, UDP sessions can appear to have failed over. However, this may not be reliable for the following reasons:

- UDP packets in the direction of the security policy must be received before reply packets can be accepted. For example, if a port1 -> port2 policy accepts UDP packets, UDP packets received at port2 destined for the network connected to port1 will not be accepted until the policy accepts UDP packets at port1 that are destined for the network connected to port2. So, if a user connects from an internal network to the Internet and starts receiving UDP packets from the Internet (for example streaming media), after a failover the user will not receive any more UDP packets until the user re-connects to the Internet site.
- UDP sessions accepted by NAT policies will not resume after a failover because NAT will usually give the new session a different source port. So only traffic for UDP protocols that can handle the source port changing during a session will continue to flow.

You can however, enable session pickup for UDP and ICMP packets by enabling session pickup for TCP sessions and then enabling session pickup for connectionless sessions:

```
config system ha
   set session-pickup enable
   set session-pickup-connectionless enable
end
```

This configuration causes the cluster units to synchronize UDP and ICMP session tables and if a failover occurs UDP and ICMP sessions are maintained.

FortiOS Carrier GTP session failover

FortiOS Carrier HA supports GTP session failover. The primary unit synchronizes the GTP tunnel state to all cluster units after the GTP tunnel setup is completed. After the tunnel setup is completed, GTP sessions use UDP and HA does not synchronize UDP sessions to all cluster units. However, similar to other UDP sessions, after a failover, since the new primary unit will have the GTP tunnel state information, GTP UDP sessions using the same tunnel can continue to flow with some limitations.

The limitation on packets continuing to flow is that there has to be a security policy to accept the packets. For example, if the FortiOS Carrier unit has an internal to external security policy, GTP UDP sessions using an established tunnel that are received by the internal interface are accepted by the security policy and can continue to flow. However, GTP UDP packets for an established tunnel that are received at the external interface cannot flow until packets from the same tunnel are received at the internal interface.

If you have bi-directional policies that accept GTP UDP sessions then traffic in either direction that uses an established tunnel can continue to flow after a failover without interruption.

Active-active HA subordinate units sessions can resume after a failover

In an active-active cluster, subordinate units process sessions. After a failover, all cluster units that are still operating may be able to continue processing the sessions that they were processing before the failover. These sessions are maintained because after the failover the new primary unit uses the HA session table to continue to send session packets to the cluster units that were processing the sessions before the failover. Cluster units maintain their own information about the sessions that they are processing and this information is not affected by the failover. In this way, the cluster units that are still operating can continue processing their own sessions without loss of data.

The cluster keeps processing as many sessions as it can. But some sessions can be lost. Depending on what caused the failover, sessions can be lost in the following ways:

- A cluster unit fails (the primary unit or a subordinate unit). All sessions that were being processed by that cluster unit are lost.
- A link failure occurs. All sessions that were being processed through the network interface that failed are lost.

This mechanism for continuing sessions is not the same as session failover because:

- Only the sessions that can be maintained are maintained.
- The sessions are maintained on the same cluster units and not re-distributed.
- Sessions that cannot be maintained are lost.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended HA configuration for WAN optimization is active-passive mode. Also, when the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions. HA also does not support WAN optimization session failover.

In a cluster, the primary unit only stores web cache and byte cache databases. These databases are not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its web and byte caches. As well, the new primary unit cannot connect to a SAS partition that the failed primary unit used.

Rebuilding the byte caches can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate units that it is participating with in WAN optimization tunnels.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time experienced by your network users may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Monitoring cluster units for failover

You can use logging and SNMP to monitor cluster units for failover. Both the primary and subordinate units can be configured to write log messages and send SNMP traps if a failover occurs. You can also log into the cluster web-based manager and CLI to determine if a failover has occurred.

NAT/Route mode active-passive cluster packet flow

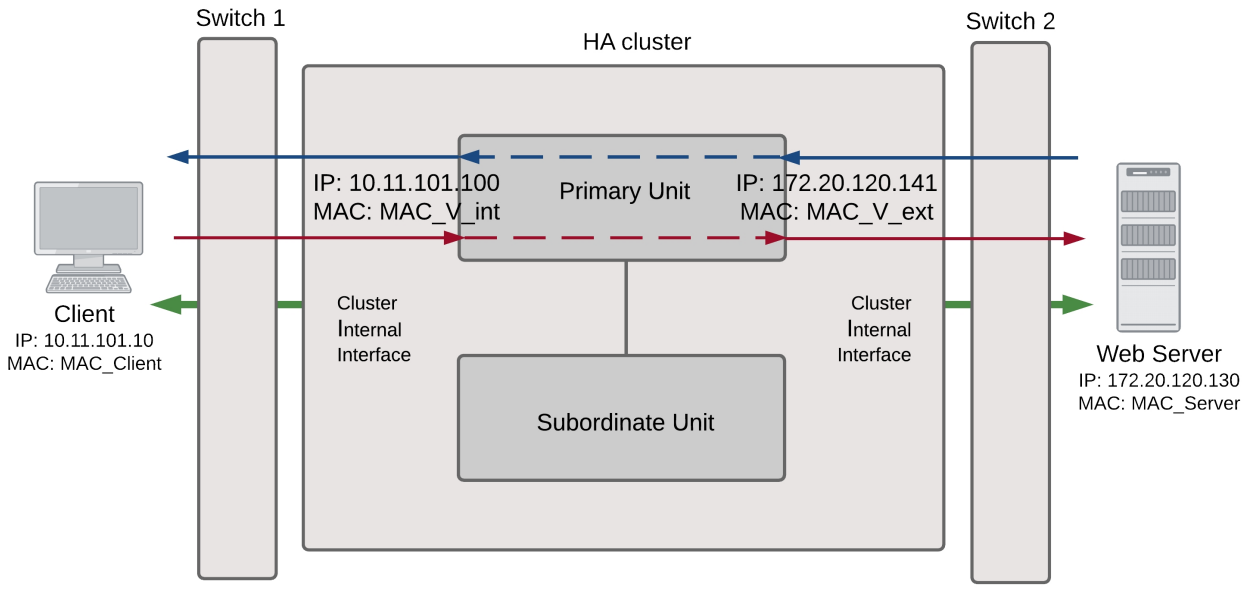
This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In an active-passive cluster operating in NAT/Route mode, four MAC addresses are involved in communication between the client and the web server when the primary unit processes the connection:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only know the cluster external virtual MAC address (MAC_V_int).

NAT/Route mode active-passive packet flow



Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_V_ext
Destination	172.20.120.130	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_V_int
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit becomes the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
   The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary units sends gratuitous ARP packets from the internal interface to the 10.11.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary units sends gratuitous ARP packets to the 172.20.120.0 to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.
   If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Transparent mode active-passive cluster packet flow

This section describes how packets are processed and how failover occurs in an active-passive HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

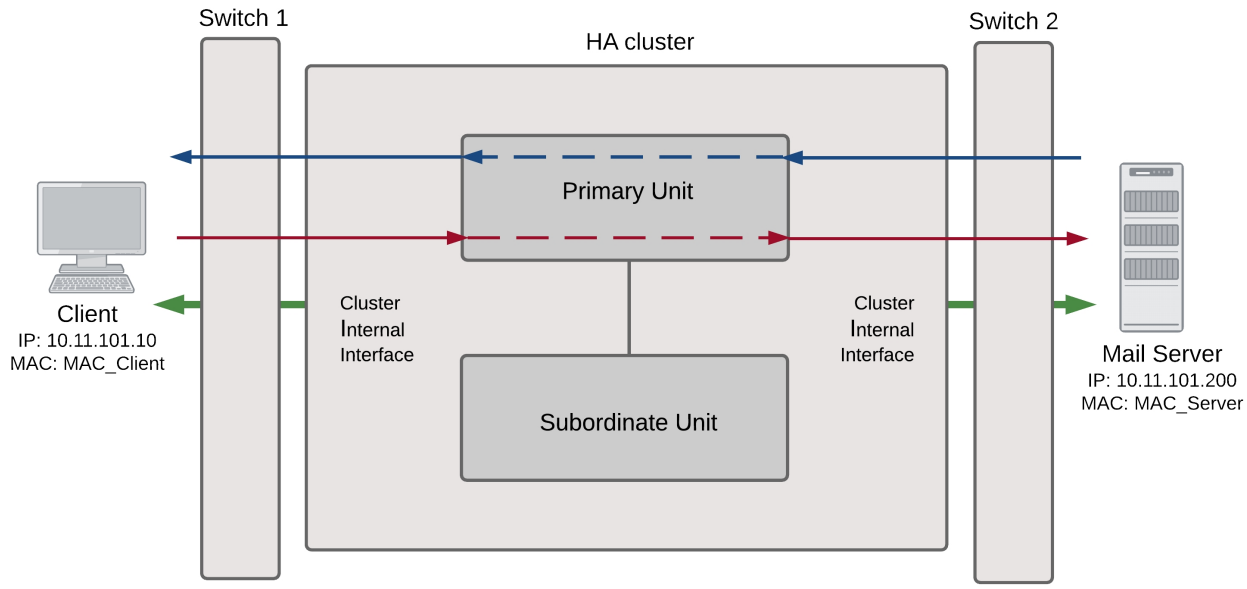
In an active-passive cluster operating in Transparent mode, two MAC addresses are involved in the communication between a client and a server when the primary unit processes a connection:

- Client MAC address (MAC_Client)
- Server MAC address (MAC_Server)

The HA virtual MAC addresses are not directly involved in communication between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and processed by the cluster.

The cluster's presence on the network is transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network segment connected to the cluster external interface with the HA virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the HA virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-passive packet flow



Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 110.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit processes the packet.
7. The primary unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

8. The primary unit continues to process packets in this way unless a failover occurs.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5. The primary unit processes the packet.
6. The primary unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

7. The primary unit continues to process packets in this way unless a failover occurs.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary units sends gratuitous ARP packets to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary units sends gratuitous ARP packets to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

   If there were more than two cluster units in the original cluster, these remaining units would become subordinate units.

Failover performance

This section describes the designed device and link failover times for a FortiGate cluster and also shows results of a failover performance test.

Device failover performance

By design FGCP device failover time is 2 seconds for a two-member cluster with ideal network and traffic conditions. If subsecond failover is enabled the failover time can drop below 1 second.

All cluster units regularly receive HA heartbeat packets from all other cluster units over the HA heartbeat link. If any cluster unit does not receive a heartbeat packet from any other cluster unit for 2 seconds, the cluster unit that has not sent heartbeat packets is considered to have failed.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions. Typically if subsecond failover is not enabled you can expect a failover time of 9 to 15 seconds depending on the cluster and network configuration. The failover time can also be increased by more complex configurations and or configurations with network equipment that is slow to respond.

You can change the `hb-lost-threshold` to increase or decrease the device failover time. See Modifying heartbeat timing on page 1462 for information about using `hb-lost-threshold`, and other heartbeat timing settings.

Link failover performance

Link failover time is controlled by how long it takes for a cluster to synchronize the cluster link database. When a link failure occurs, the cluster unit that experienced the link failure uses HA heartbeat packets to broadcast the updated link database to all cluster units. When all cluster units have received the updated database the failover is complete.

It may take another few seconds for the cluster to negotiate and re-distribute communication sessions.

Reducing failover times

- Keep the network configuration as simple as possible with as few as possible network connections to the cluster.
- If possible operate the cluster in Transparent mode.
- Use high-performance switches to that the switches failover to interfaces connected to the new primary unit as quickly as possible.
- Use accelerated FortiGate interfaces. In some cases accelerated interfaces will reduce failover times.
- Make sure the FortiGate unit sends multiple gratuitous arp packets after a failover. In some cases, sending more gratuitous arp packets will cause connected network equipment to recognize the failover sooner. To send 10 gratuitous arp packets:

```
config system ha
   set arps 10
end
```

- Reduce the time between gratuitous arp packets. This may also caused connected network equipment to recognize the failover sooner. To send 50 gratuitous arp packets with 1 second between each packet:

```
config system ha
   set arps 50
   set arps-interval 1
end
```

- Reduce the number of lost heartbeat packets and reduce the heartbeat interval timers to be able to more quickly detect a device failure. To set the lost heartbeat threshold to 3 packets and the heartbeat interval to 100 milliseconds:

```
config system ha
   set hb-interval 1
   set hb-lost-threshold 3
end
```

- Reduce the hello state hold down time to reduce the amount of the time the cluster waits before transitioning from the hello to the work state. To set the hello state hold down time to 5 seconds:

```
config system ha
   set helo-holddown 5
end
```

- Enable sending a link failed signal after a link failover to make sure that attached network equipment responds a quickly as possible to a link failure. To enable the link failed signal:

```
config system ha
   set link-failed-signal enable
end
```

HA and load balancing

FGCP active-active (a-a) load balancing distributes network traffic among all of the units in a cluster. Load balancing can improve cluster performance because the processing load is shared among multiple cluster units.

This chapter describes how active-active load balancing works and provides detailed active-active HA NAT/Route and Transparent mode packet flow descriptions.

Load balancing overview

FGCP active-active HA uses a technique similar to unicast load balancing in which the primary unit is associated with the cluster HA virtual MAC addresses and cluster IP addresses. The primary unit is the only cluster unit to receive packets sent to the cluster. The primary unit then uses a load balancing schedule to distribute sessions to all of the units in the cluster (including the primary unit). Subordinate unit interfaces retain their actual MAC addresses and the primary unit communicates with the subordinate units using these MAC addresses. Packets exiting the subordinate units proceed directly to their destination and do not pass through the primary unit first.

By default, active-active HA load balancing distributes proxy-based security profile processing to all cluster units. Proxy-based security profile processing is CPU and memory-intensive, so FGCP load balancing may result in higher throughput because resource-intensive processing is distributed among all cluster units.

Proxy-based security profile processing that is load balanced includes proxy-based virus scanning, proxy-based web filtering, proxy-based email filtering, and proxy-based data leak prevention (DLP) of HTTP, FTP, IMAP, IMAPS, POP3, POP3S, SMTP, SMTPS, IM, and NNTP, sessions accepted by security policies.

Other features enabled in security policies such as Endpoint security, traffic shaping and authentication have no effect on active-active load balancing.

You can also enable `load-balance-all` to have the primary unit load balance all TCP sessions. Load balancing TCP sessions increases overhead and may actually reduce performance so it is disabled by default. You can also enable `load-balance-udp` to have the primary unit load balance all UDP sessions. Load balancing UDP sessions also increases overhead so it is also disabled by default.

NP4 and NP6 processors can also offload and accelerate load balancing.

During active-active HA load balancing the primary unit uses the configured load balancing schedule to determine the cluster unit that will process a session. The primary unit stores the load balancing information for each load balanced session in the cluster load balancing session table. Using the information in this table, the primary unit can then forward all of the remaining packets in each session to the appropriate cluster unit. The load balancing session table is synchronized among all cluster units.

HTTPS, ICMP, multicast, and broadcast sessions are never load balanced and are always processed by the primary unit. IPS,Application Control, flow-based virus scanning, flow-based web filtering, flow-based DLP, flow-based email filtering, VoIP, IM, P2P, IPsec VPN, HTTPS, SSL VPN, HTTP multiplexing, SSL offloading, WAN optimization, explicit web proxy, and WCCP sessions are also always processed only by the primary unit.

In addition to load balancing, active-active HA also provides the same session, device and link failover protection as active-passive HA. If the primary unit fails, a subordinate unit becomes the primary unit and resumes operating the cluster.

Active-active HA also maintains as many load balanced sessions as possible after a failover by continuing to process the load balanced sessions that were being processed by the cluster units that are still operating. See Active-active HA subordinate units sessions can resume after a failover on page 1501 for more information.

Load balancing schedules

The load balancing schedule controls how the primary unit distributes packets to all cluster units. You can select from the following load balancing schedules.

Schedule	Description
None	No load balancing. Select None when the cluster interfaces are connected to load balancing switches. If you select None, the Primary unit does not load balance traffic and the subordinate units process incoming traffic that does not come from the Primary unit. For all other load balancing schedules, all traffic is received first by the Primary unit, and then forwarded to the subordinate units. The subordinate units only receive and process packets sent from the primary unit.
Hub	Load balancing if the cluster interfaces are connected to a hub. Traffic is distributed to cluster units based on the source IP and destination IP of the packet.
Least-Connection	If the cluster units are connected using switches, select **Least Connection** to distribute network traffic to the cluster unit currently processing the fewest connections.
Round-Robin	If the cluster units are connected using switches, select Round-Robin to distribute network traffic to the next available cluster unit.
Weighted Round-Robin	Similar to round robin, but weighted values are assigned to each of the units in a cluster based on their capacity and on how many connections they are currently processing. For example, the primary unit should have a lower weighted value because it handles scheduling and forwards traffic. Weighted round robin distributes traffic more evenly because units that are not processing traffic will be more likely to receive new connections than units that are very busy.
Random	If the cluster units are connected using switches, select Random to randomly distribute traffic to cluster units.
IP	Load balancing according to IP address. If the cluster units are connected using switches, select **IP** to distribute traffic to units in a cluster based on the source IP and destination IP of the packet.
IP Port	Load balancing according to IP address and port. If the cluster units are connected using switches, select IP Port to distribute traffic to units in a cluster based on the source IP, source port, destination IP, and destination port of the packet.

Once a packet has been propagated to a subordinate unit, all packets are part of that same communication session are also propagated to that same subordinate unit. Traffic is distributed according to communication session, not just according to individual packet.

Any subordinate unit that receives a forwarded packet processes it, without applying load balancing. Note that subordinate units are still considered to be active, because they perform routing, virus scanning, and other FortiGate unit tasks on their share of the traffic. Active subordinate units also share their session and link status

information with all cluster units. The only things that active members do not do is make load balancing decisions.

Even though the primary unit is responsible for the load balancing process, the primary unit still acts like a FortiGate unit in that it processes packets, performing, routing, firewall, virus scanning, and other FortiGate unit tasks on its share of the traffic. Depending on the load balancing schedule used, the primary unit may assign itself a smaller share of the total load.

More about active-active failover

If a subordinate unit fails, the primary unit re-distributes the sessions that the subordinate was processing among the remaining active cluster members. If the primary unit fails, the subordinate units negotiate to select a new primary unit. The new primary unit continues to distribute packets among the remaining active cluster units.

Failover works in a similar way if the cluster consists of only two units. If the primary unit fails the subordinate unit negotiates and becomes the new primary unit. If the subordinate unit fails, the primary unit processes all traffic. In both cases, the single remaining unit continues to function as a primary unit, maintaining the HA virtual MAC address for all of its interfaces.

HTTPS sessions, active-active load balancing, and proxy servers

To prevent HTTPS web filtering problems active-active HA does not load balance HTTPS sessions. The FortiGate unit identifies HTTPS sessions as all sessions received on the HTTPS TCP port. The default HTTPS port is 443. You can go to **Policy & Objects > Policy > SSL/SSH Inspection** to use a custom port for HTTPS sessions. If you change the HTTPS port, the FGCP stops load balancing all sessions that use the custom HTTPS port.

Normally you would not change the HTTPS port. However, if your network uses a proxy server for HTTPS traffic you may have to change to the custom HTTPS port used by your proxy server. If your network uses a proxy server you might also use the same port for both HTTP and HTTPS traffic. In this case you would configure the FortiGate unit to use custom ports for both HTTP and HTTPS traffic. Go to **Policy & Objects > Policy > Proxy Options** to use a custom port for HTTP.

Using the same port for HTTP and HTTPS traffic can cause problems with active-active clusters because active-active clusters always load balance HTTP traffic. If both HTTP and HTTPS use the same port, the active-active cluster cannot differentiate between HTTP and HTTPS traffic and will load balance both.

As mentioned above, load balancing HTTPS traffic may cause problems with HTTPS web filtering. To avoid this problem, you should configure your proxy server to use different ports for HTTP and HTTPS traffic. Then configure your cluster to also use different ports for HTTP and HTTPS.

Selecting a load balancing schedule

You can select the load balancing schedule when initially configuring the cluster and you can change the load balancing schedule at any time while the cluster is operating without affecting cluster operation.

You can select a load balancing schedule from the CLI. Use the following command to select a load balancing schedule:

```
config system ha
   set schedule {hub | ip | ipport | leastconnection | none | random | round-robin
       | weight-round-robin}
end
```

Load balancing TCP and UDP sessions

You can use the following command to configure the cluster to load balance TCP sessions in addition to security profile sessions.

```
config system ha
   set load-balance-all enable
end
```

Enabling `load-balance-all` to add load balancing of TCP sessions may not improve performance because the cluster requires additional overhead to load balance sessions. Load balancing aTCP session usually requires about as much overhead as just processing it. On the other hand, TCP load balancing performance may be improved if your FortiGate unit includes NP4 or NP6 processors.

You can enable `load-balance-all` and monitor network performance to see if it improves. If performance is not improved, you might want to change the HA mode to active-passive since active-active HA is not providing any benefit.

On some FortiGate models you can use the following command to also load balance UDP sessions:

```
config system ha
   set load-balance-udp enable
end
```

Similar to load balancing TCP sessions, load balancing UDP sessions may also not improve performance. Also UDP load balancing performance may ber improved with NP4 and NP6 processors.

Using NP4 or NP6 processors to offload load balancing

FortiGates that include NP4 and NP6 network processors can provide hardware acceleration for active-active HA cluster by offloading load balancing from the primary unit CPU. Network processors are especially useful when load balancing TCP and UDP sessions.

The first packet of every new session is received by the primary unit and the primary unit uses its load balancing schedule to select the cluster unit that will process the new session. This information is passed back to the network processor and all subsequent packets of the same sessions are offloaded to the network processor which sends the packet directly to a subordinate unit. Load balancing is effectively offloaded from the primary unit to the network processor resulting in a faster and more stable active-active cluster.

To take advantage of network processor load balancing acceleration, connect the cluster unit interfaces with network processors to the busiest networks. Connect non-accelerated interfaces to less busy networks. No special FortiOS or HA configuration is required. Network processor acceleration of active-active HA load balancing is supported for any active-active HA configuration or active-active HA load balancing schedule.

Configuring weighted-round-robin weights

You can configure weighted round-robin load balancing for a cluster and configure the static weights for each of the cluster units according to their priority in the cluster. When you set `schedule` to `weight-round-robin` you can use the `weight` option to set the static weight of each cluster unit. The static weight is set according to the priority of each unit in the cluster. A FortiGate HA cluster can contain up to four FortiGate units so you can set up to 4 static weights.

The priority of a cluster unit is determined by its device priority, the number of monitored interfaces that are functioning, its age in the cluster and its serial number. Priorities are used to select a primary unit and to set an

order of all of the subordinate units. Thus the priority order of a cluster unit can change depending on configuration settings, link failures and so on. Since weights are also set using this priority order the weights are independent of specific cluster units but do depend on the role of the each unit in the cluster.

You can use the following command to display the priority order of units in a cluster. The following example displays the priority order for a cluster of 5 FortiGate units:

```
get system ha status
   Model: 620
   Mode: a-p
   Group: 0
   Debug: 0
   ses_pickup: disable
   Master:150 head_office_cla FG600B3908600825 0
   Slave :150 head_office_clb FG600B3908600705 1
   Slave :150 head_office_clc FG600B3908600702 2
   Slave :150 head_office_cld FG600B3908600605 3
   Slave :150 head_office_cle FG600B3908600309 4
   number of vcluster: 1
   vcluster 1: work 169.254.0.1
   Master:0 FG600B3908600825
   Slave :1 FG600B3908600705
   Slave :2 FG600B3908600702
   Slave :3 FG600B3908600605
   Slave :4 FG600B3908600309
```

The cluster units are listed in priority order starting at the 6th output line. The primary unit always has the highest priority and is listed first followed by the subordinate units in priority order. The last 5 output lines list the cluster units in vcluster 1 and are not always in priority order.

The default static weight for each cluster unit is 40. This means that sessions are distributed evenly among all cluster units. You can use the `set weight` command to change the static weights of cluster units to distribute sessions to cluster units depending on their priority in the cluster. The weight can be between 0 and 255. Increase the weight to increase the number of connections processed by the cluster unit with that priority.

You set the weight for each unit separately. For the example cluster of 5 FortiGate units you can set the weight for each unit as follows:

```
config system ha
   set mode a-a
   set schedule weight-roud-robin
   set weight 0 5
   set weight 1 10
   set weight 2 15
   set weight 3 20
   set weight 4 30
end
```

If you enter the `get` command to view the HA configuration the output for `weight` would be:

```
weight 5 10 15 20 30 40 40 40 40 40 40 40 40 40 40 40
```

This configuration has the following results if the output of the `get system ha status` command is that shown above:

- The first five connections are processed by the primary unit (host name head_office_cla, priority 0, weight 5). From the output of the
- The next 10 connections are processed by the first subordinate unit (host name head_office_clb, priority 1, weight 10)

- The next 15 connections are processed by the second subordinate unit (host name head_office_clc, priority 2, weight 15)
- The next 20 connections are processed by the third subordinate unit (host name head_office_cld, priority 3, weight 20)
- The next 30 connections are processed by the fourth subordinate unit (host name head_office_cle, priority 4, weight 30)

Dynamically optimizing weighted load balancing according to how busy cluster units are

In conjunction with using static weights to load balance sessions among cluster units you can configure a cluster to dynamically load balance sessions according to individual cluster unit CPU usage, memory usage, and number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy-based security proflie sessions. If any of these system loading indicators increases above configured thresholds, weighted load balancing dynamically sends fewer new sessions to the busy unit until it recovers.

High CPU or memory usage indicates that a unit is under increased load and may not be able to process more sessions. HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy use are also good indicators of how busy a cluster unit is, since processing high numbers of these proxy sessions can quickly reduce overall cluster unit performance.

For example, you can set a CPU usage high watermark threshold. When a cluster unit reaches this high watermark threshold fewer sessions are sent to it. With fewer sessions to process the cluster unit's CPU usage should fall back to the low watermark threshold. When the low watermark threshold is reached the cluster resumes normal load balancing of sessions to the cluster unit.

You can set individual high and low watermark thresholds and weights for CPU usage, memory usage, and for the number of HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions.

The CPU usage, memory usage, and proxy weights determine how the cluster load balances sessions when a high watermark threshold is reached and also affect how the cluster load balances sessions when multiple cluster units reach different high watermark thresholds at the same time. For example, you might be less concerned about a cluster unit reaching the memory usage high watermark threshold than reaching the CPU usage high watermark threshold. If this is the case you can set the weight lower for memory usage. Then, if one cluster unit reaches the CPU usage high watermark threshold and a second cluster unit reaches the memory usage high watermark threshold the cluster will load balance more sessions to the cluster unit with high memory usage and fewer sessions to the cluster unit with high CPU usage. As a result, reaching the CPU usage high watermark will have a greater affect on how sessions are redistributed than reaching the memory usage high watermark.

When a high watermark threshold is reached, the corresponding weight is subtracted from the static weight of the cluster unit. The lower the weight the fewer the number of sessions that are load balanced to that unit. Subsequently when the low watermark threshold is reached, the static weight of the cluster unit returns to its configured value. For the weights to all be effective the weights assigned to the load indicators should usually be lower than or equal to the static weights assigned to the cluster units.

Use the following command to set thresholds and weights for CPU and memory usage and HTTP, FTP, IMAP, POP3, SMTP, or NNTP proxy sessions:

```
config system ha
   set mode a-a
   set schedule weight-round-robin
   set cpu-threshold <weight> <low> <high>
   set memory-threshold <weight> <low> <high>
   set http-proxy-threshold <weight> <low> <high>
   set ftp-proxy-threshold <weight> <low> <high>
   set imap-proxy-threshold <weight> <low> <high>
```

```
    set nntp-proxy-threshold <weight> <low> <high>
    set pop3-proxy-threshold <weight> <low> <high>
    set smtp-proxy-threshold <weight> <low> <high>
end
```

For each option, the weight range is 0 to 255 and the default weight is 5. The low and high watermarks are a percent (0 to 100). The default low and high watermarks are 0 which means they are disabled. The default configuration when weighted load balancing is enabled looks like the following:

```
config system ha
    set mode a-a
    set schedule weight-round-robin
    set cpu-threshold 5 0 0
    set memory-threshold 5 0 0
    set http-proxy-threshold 5 0 0
    set ftp-proxy-threshold 5 0 0
    set imap-proxy-threshold 5 0 0
    set nntp-proxy-threshold 5 0 0
    set pop3-proxy-threshold 5 0 0
    set smtp-proxy-threshold 5 0 0
end
```

When you first enable HA weighted load balancing, the weighted load balancing configuration is synchronized to all cluster units and each cluster unit has the default configuration shown above. Changes to the CPU, memory, HTTP, FTP, IMAP, NNTP, POP3, and SMTP proxy thresholds and low and high watermarks must be made for each cluster unit and are not synchronized to the other cluster units.

When you configure them, the high watermarks must be greater than their corresponding low watermarks.

For CPU and memory usage the low and high watermarks are compared with the percentage CPU and memory use of the cluster unit. For each of the proxies the high and low watermarks are compared to a number that represents percent of the max number of proxy sessions being used by a proxy. This number is calculated using the formula:

```
proxy usage = (current sessions * 100) / max sessions
```

where:

`current sessions` is the number of active sessions for the proxy type.

`max sessions` is the session limit for the proxy type. The session limit depends on the FortiGate unit and its configuration.

You can use the following command to display the maximum and current number of sessions for a proxy:

```
get test {ftpd | http | imap | nntp | pop3 | smtp} 4
```

You can use the following command to display the maximum number of sessions and the and current number of sessions for all of the proxies:

```
get test proxyworker 4
```

The command output includes lines similar to the following:

```
get test http 4
HTTP Common
Current Connections             5000/8032
```

In the example, `5000` is the current number of proxy connections being used by HTTP and 8032 is the maximum number of proxy sessions allowed. For this example the proxy usage would be:

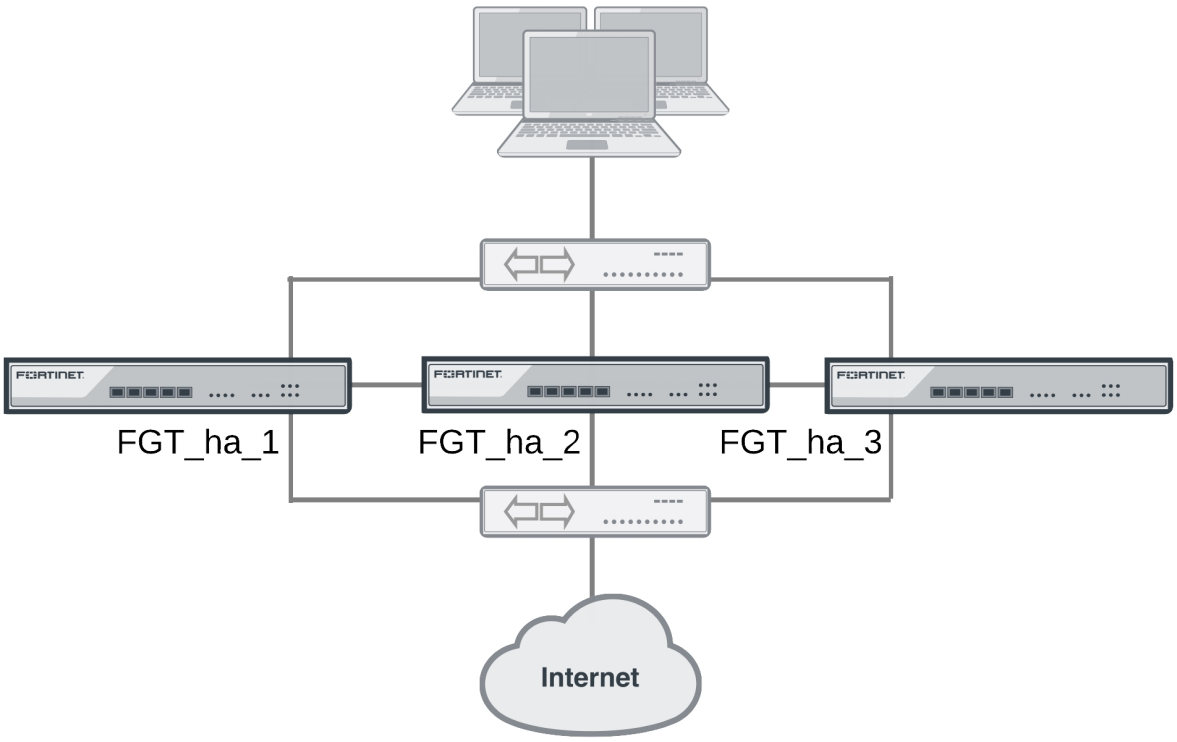
```
proxy usage = (5000 * 100) / 8032
```

```
proxy usage = 62%
```

Example weighted load balancing configuration

Consider a cluster of three FortiGate units with host names FGT_ha_1, FGT_ha_2, and FGT_ha_3 as shown below. This example describes how to configure weighted load balancing settings for CPU and memory usage for the cluster and then to configure HTTP and POP3 proxy weights to send most HTTP and POP3 proxy sessions to different cluster units.

Example HA weighted load balancing configuration



Connect to the cluster CLI and use the following command to set the CPU usage threshold weight to 30, low watermark to 60, and high watermark to 80. This command also sets the memory usage threshold weight to 10, low watermark to 60, and high watermark to 90.

```
config system ha
   set mode a-a
   set schedule weight-round-robin
   set cpu-threshold 30 60 80
   set memory-threshold 10 60 90
end
```

The static weights for the cluster units remain at the default values of 40. Since this command changes the mode to `a-a` and the schedule to `weight-round-robin` for the first time, the weight settings are synchronized to all cluster units.

As a result of this configuration, if the CPU usage of any cluster unit (for example, FGT_ha_1) reaches 80% the static weight for that cluster unit is reduced from 40 to 10 and only 10 of every 120 new sessions are load balanced to this cluster unit. If the memory usage of FGT_ha_1 also reaches 90% the static weight further reduces to 0 and no new sessions are load balanced to FGT_ha_1. Also, if the memory usage of 620_ha_2 reaches 90% the static weight of FGT_ha_2 reduces to 30 and 30 of every 120 new sessions are load balanced to FGT_ha_2.

Now that you have established the weight load balancing configuration for the entire cluster you can monitor the cluster to verify that processing gets distributed evenly to all cluster units. From the web-based manager you can go do **System > Config > HA > View HA Statistics** and see the CPU usage, active sessions, memory usage and other statistics for all of the cluster units. If you notice that one cluster unit is more or less busy than others you can adjust the dynamic weights separately for each cluster unit.

For example, in some active-active clusters the primary unit may tend to be busier than other cluster units because in addition to processing sessions the primary unit also receives all packets sent to the cluster and performs load balancing to distribute the sessions to other cluster units. To reduce the load on the primary unit you could reduce the CPU and memory usage high watermark thresholds for the primary unit so that fewer sessions are distributed to the primary unit. You could also reduce the primary unit's high watermark setting for the proxies to distribute more proxy sessions to other cluster units.

This would only be useful if you are using device priorities and override settings to make sure the same unit always becomes the primary unit. See An introduction to the FGCP on page 1270.

If the example cluster is configured for FGT_ha_2 to be the primary unit, connect to the FGT_ha_2's CLI and enter the following command to set CPU usage, memory usage, and proxy usage high watermark thresholds lower.

```
config system ha
   set cpu-threshold 30 60 70
   set memory-threshold 30 60 70
   set http-proxy-threshold 30 60 70
   set ftp-proxy-threshold 30 60 70
   set imap-proxy-threshold 30 60 70
   set nntp-proxy-threshold 30 60 70
   set pop3-proxy-threshold 30 60 70
   set smtp-proxy-threshold 30 60 70
end
```

As a result, when any of these factors reaches 70% on the primary unit, fewer sessions will be processed by the primary unit, preventing the number of sessions being processed from rising.

NAT/Route mode active-active cluster packet flow

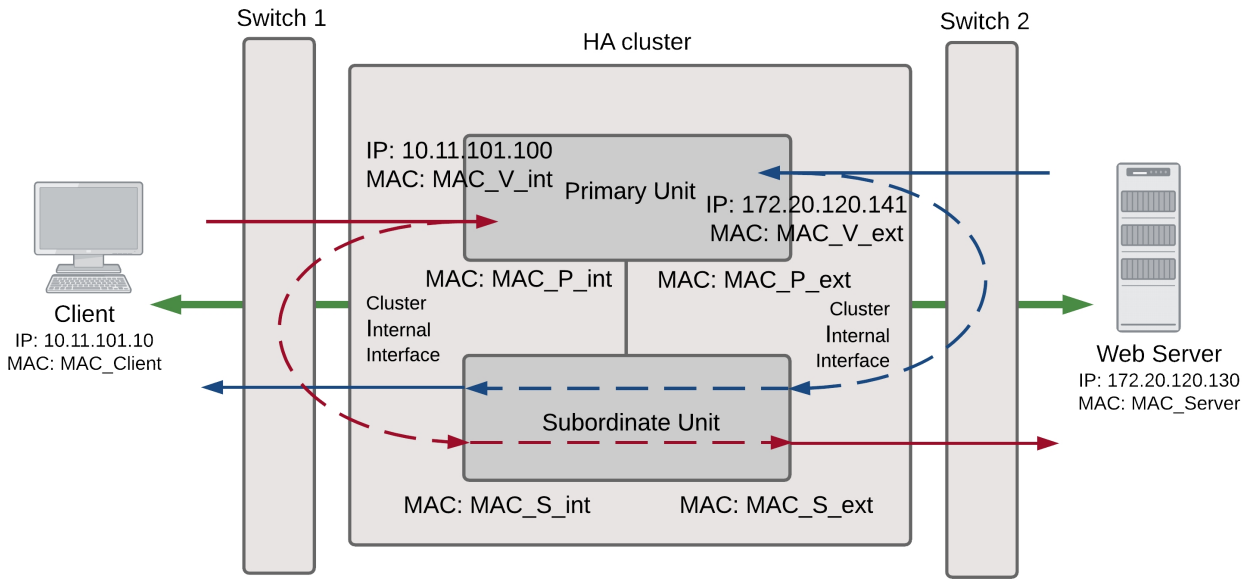
This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in NAT/Route mode. In the example, the NAT/Route mode cluster acts as the internet firewall for a client computer's internal network. The client computer's default route points at the IP address of the cluster internal interface. The client connects to a web server on the Internet. Internet routing routes packets from the cluster external interface to the web server, and from the web server to the cluster external interface.

In NAT/Route mode, eight MAC addresses are involved in active-active communication between the client and the web server when the primary unit load balances packets to the subordinate unit:

- Internal virtual MAC address (MAC_V_int) assigned to the primary unit internal interface,
- External virtual MAC address (MAC_V_ext) assigned to the primary unit external interface,
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

In NAT/Route mode, the HA cluster works as a gateway when it responds to ARP requests. Therefore, the client and server only know the gateway MAC addresses. The client only knows the cluster internal virtual MAC address (MAC_V_int) and the server only knows the cluster external virtual MAC address (MAC_V_ext).

NAT/Route mode active-active packet flow



Packet flow from client to web server

1. The client computer requests a connection from 10.11.101.10 to 172.20.120.130.
2. The default route on the client computer recognizes 10.11.101.100 (the cluster IP address) as the gateway to the external network where the web server is located.
3. The client computer issues an ARP request to 10.11.101.100.
4. The primary unit intercepts the ARP request, and responds with the internal virtual MAC address (MAC_V_int) which corresponds to its IP address of 10.11.101.100.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address

Source	10.11.101.10	MAC_Client
Destination	172.20.120.130	MAC_V_int

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_P_int
Destination	172.20.120.130	MAC_S_int

7. The subordinate unit recognizes that the packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the web server.

	IP address	MAC address
Source	172.20.120.141	MAC_S_ext
Destination	172.20.120.130	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from web server to client

1. When the web server responds to the client's packet, the cluster external interface IP address (172.20.120.141) is recognized as the gateway to the internal network.
2. The web server issues an ARP request to 172.20.120.141.
3. The primary unit intercepts the ARP request, and responds with the external virtual MAC address (MAC_V_ext) which corresponds its IP address of 172.20.120.141.
4. The web server then sends response packets to the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_Server
Destination	172.20.120.141	MAC_V_ext

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	172.20.120.130	MAC_P_ext
Destination	172.20.120.141	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	172.20.120.130	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails, the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC addresses.
   The new primary unit has the same IP addresses and MAC addresses as the failed primary unit.
3. The new primary units sends gratuitous ARP packets to the 10.10.101.0 network to associate its internal IP address with the internal virtual MAC address.
4. The new primary units sends gratuitous ARP packets to the 172.20.120.0 network to associate its external IP address with the external virtual MAC address.
5. Traffic sent to the cluster is now received and processed by the new primary unit.
   If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

Transparent mode active-active cluster packet flow

This section describes an example of how packets are load balanced and how failover occurs in an active-active HA cluster running in Transparent mode. The cluster is installed on an internal network in front of a mail server and the client connects to the mail server through the Transparent mode cluster.

In Transparent mode, six MAC addresses are involved in active-active communication between a client and a server when the primary unit load balances packets to the subordinate unit:

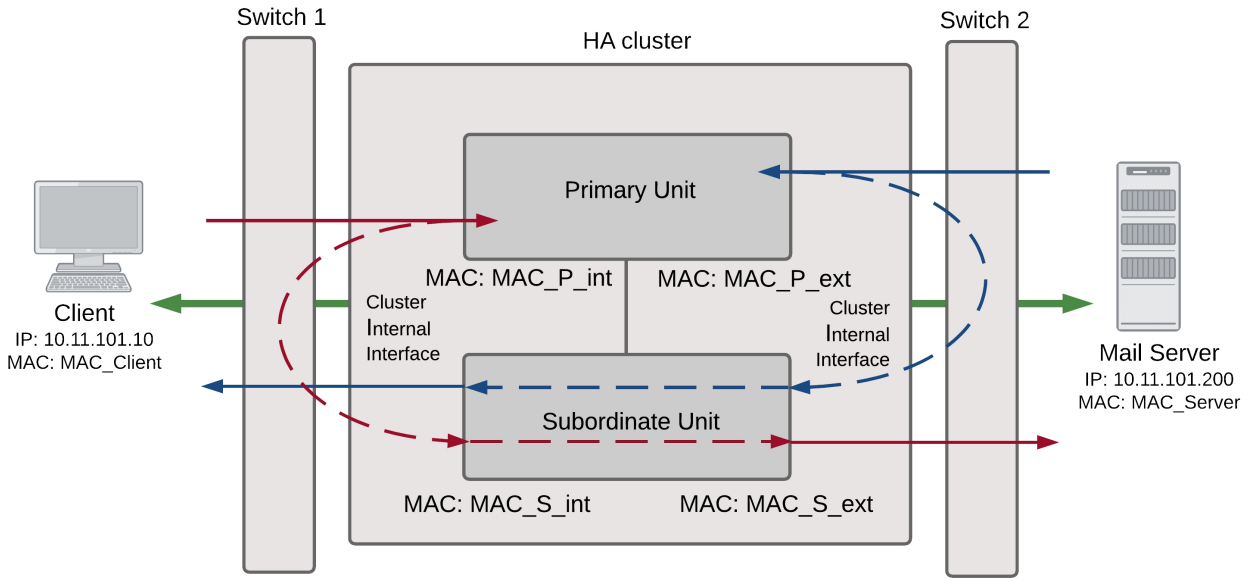
- Client MAC address (MAC_Client),
- Server MAC address (MAC_Server),
- Primary unit original internal MAC address (MAC_P_int),
- Primary unit original external MAC address (MAC_P_ext),
- Subordinate unit internal MAC address (MAC_S_int),
- Subordinate unit external MAC address (MAC_S_ext).

The HA virtual MAC addresses are not directly involved in communicate between the client and the server. The client computer sends packets to the mail server and the mail server sends responses. In both cases the packets are intercepted and load balanced among cluster members.

The cluster's presence on the network and its load balancing are transparent to the client and server computers. The primary unit sends gratuitous ARP packets to Switch 1 that associate all MAC addresses on the network

segment connected to the cluster external interface with the external virtual MAC address. The primary unit also sends gratuitous ARP packets to Switch 2 that associate all MAC addresses on the network segment connected to the cluster internal interface with the internal virtual MAC address. In both cases, this results in the switches sending packets to the primary unit interfaces.

Transparent mode active-active packet flow



Packet flow from client to mail server

1. The client computer requests a connection from 10.11.101.10 to 10.11.101.200.
2. The client computer issues an ARP request to 10.11.101.200.
3. The primary unit forwards the ARP request to the mail server.
4. The mail server responds with its MAC address (MAC_Server) which corresponds to its IP address of 10.11.101.200. The primary unit returns the ARP response to the client computer.
5. The client's request packet reaches the primary unit internal interface.

	IP address	MAC address
Source	10.11.101.10	MAC_Client
Destination	10.11.101.200	MAC_Server

6. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit internal interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit internal interface.

	IP address	MAC address

Source	10.11.101.10	MAC_P_int
Destination	10.11.101.200	MAC_S_int

7. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
8. The subordinate unit forwards the packet from its external interface to the mail server.

	IP address	MAC address
Source	10.11.101.10	MAC_S_ext
Destination	10.11.101.200	MAC_Server

9. The primary unit forwards further packets in the same session to the subordinate unit.
10. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

Packet flow from mail server to client

1. To respond to the client computer, the mail server issues an ARP request to 10.11.101.10.
2. The primary unit forwards the ARP request to the client computer.
3. The client computer responds with its MAC address (MAC_Client) which corresponds to its IP address of 10.11.101.10. The primary unit returns the ARP response to the mail server.
4. The mail server's response packet reaches the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_Server
Destination	10.11.101.10	MAC_Client

5. The primary unit decides that the subordinate unit should handle this packet, and forwards it to the subordinate unit external interface. The source MAC address of the forwarded packet is changed to the actual MAC address of the primary unit external interface.

	IP address	MAC address
Source	10.11.101.200	MAC_P_ext
Destination	10.11.101.10	MAC_S_ext

6. The subordinate unit recognizes that packet has been forwarded from the primary unit and processes it.
7. The subordinate unit forwards the packet from its internal interface to the client.

	IP address	MAC address
Source	10.11.101.200	MAC_S_int
Destination	10.11.101.10	MAC_Client

8. The primary unit forwards further packets in the same session to the subordinate unit.
9. Packets for other sessions are load balanced by the primary unit and either sent to the subordinate unit or processed by the primary unit.

When a failover occurs

The following steps are followed after a device or link failure of the primary unit causes a failover.

1. If the primary unit fails the subordinate unit negotiates to become the primary unit.
2. The new primary unit changes the MAC addresses of all of its interfaces to the HA virtual MAC address.
3. The new primary units sends gratuitous ARP requests to switch 1 to associate its MAC address with the MAC addresses on the network segment connected to the external interface.
4. The new primary units sends gratuitous ARP requests to switch 2 to associate its MAC address with the MAC addresses on the network segment connected to the internal interface.
5. Traffic sent to the cluster is now received and processed by the new primary unit.

   If there were more than two cluster units in the original cluster, the new primary unit would load balance packets to the remaining cluster members.

HA with FortiGate-VM and third-party products

This chapter provides information about operating FortiOS VM cluster and operating FortiGate clusters with third party products such as layer-2 and layer-3 switches.

FortiGate-VM for VMware HA configuration

If you want to combine two or more FortiGate-VM instances into a FortiGate Clustering Protocol (FGSP) High Availability (HA) cluster the VMware server's virtual switches used to connect the heartbeat interfaces must operate in promiscuous mode. This permits HA heartbeat communication between the heartbeat interfaces. HA heartbeat packets are non-TCP packets that use Ethertype values 0x8890, 0x8891, and 0x8893. The FGCP uses link-local IP4 addresses in the 169.254.0.x range for HA heartbeat interface IP addresses.

To enable promiscuous mode in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect heartbeat interfaces.
4. In the **Properties** window left pane, select **vSwitch** and then select **Edit**.
5. Select the **Security** tab, set **Promiscuous Mode** to **Accept**, then select **OK**.
6. Select **Close**.

You must also set the virtual switches connected to other FortiGate interfaces to allow MAC address changes and to accept forged transmits. This is required because the FGCP sets virtual MAC addresses for all FortiGate interfaces and the same interfaces on the different VM instances in the cluster will have the same virtual MAC addresses.

To make the required changes in VMware:

1. In the vSphere client, select your VMware server in the left pane and then select the **Configuration** tab in the right pane.
2. In **Hardware**, select **Networking**.
3. Select **Properties** of a virtual switch used to connect FortiGate VM interfaces.
4. Set **MAC Address Changes**to**Accept**.
5. Set **Forged Transmits** to **Accept**.

FortiGate VM for Hyper-V HA configuration

Promiscuous mode and support for MAC address spoofing is required for FortiGate-VM for Hyper-V to support FortiGate Clustering Protocol (FGCP) high availability (HA). By default the FortiGate-VM for Hyper-V has promiscuous mode enabled in the XML configuration file in the FortiGate-VM Hyper-V image. If you have problems with HA mode, confirm that this is still enabled.

In addition, because the FGCP applies virtual MAC addresses to FortiGate data interfaces and because these virtual MAC addresses mean that matching interfaces of different FortiGate-VM instances will have the same virtual MAC addresses you have to configure Hyper-V to allow MAC spoofing. But you should only enable MAC

spoofing for FortiGate-VM data interfaces. You should not enable MAC spoofing for FortiGate HA heartbeat interfaces.

With promiscuous mode enabled and the correct MAC spoofing settings you should be able to configure HA between two or more FortiGate-VM for Hyper-V instances.

Troubleshooting layer-2 switches

Issues may occur because of the way an HA cluster assigns MAC addresses to the primary unit. Two clusters with the same group ID cannot connect to the same switch and cannot be installed on the same network unless they are separated by a router.

Forwarding delay on layer 2 switches

You must ensure that if there is a switch between the FortiGate HA cluster and the network its is protecting and the switch has a forwarding delay (even if spanning tree is disabled) when one of its interfaces is activated then the forwarding delay should be set as low as possible. For example, some versions of Cisco IOS have a forwarding delay of 15 seconds even when spanning tree is disabled. If left at this default value then TCP session pickup can fail because traffic is not forwarded through the switch on HA failover.

Failover issues with layer-3 switches

After a failover, the new primary unit sends gratuitous ARP packets to refresh the MAC forwarding tables of the switches connected to the cluster. If the cluster is connected using layer-2 switches, the MAC forwarding tables (also called arp tables) are refreshed by the gratuitous ARP packets and the switches start directing packets to the new primary unit.

In some configurations that use layer-3 switches, after a failover, the layer-3 switches may not successfully re-direct traffic to the new primary unit. The possible reason for this is that the layer-3 switch might keep a table of IP addresses and interfaces and may not update this table for a relatively long time after the failover (the table is not updated by the gratuitous ARP packets). Until the table is updated, the layer-3 switch keeps forwarding packets to the now failed cluster unit. As a result, traffic stops and the cluster does not function.

As of the release date of this document, Fortinet has not developed a workaround for this problem. One possible solution would be to clear the forwarding table on the layer-3 switch.

The `config system ha link-failed-signal` command described in Updating MAC forwarding tables when a link failover occurs on page 1489 can be used to resolve link failover issues similar to those described here.

Changing spanning tree protocol settings for some switches

Configuration changes may be required when you are running an active-active HA cluster that is connected to a switch that operates using the spanning tree protocol. For example, the following spanning tree parameters may need to be changed:

Maximum Age	The time that a bridge stores the spanning tree bridge control data unit (BPDU) before discarding it. A maximum age of 20 seconds means it may take 20 seconds before the switch changes a port to the listening state.
Forward Delay	The time that a connected port stays in listening and learning state. A forward delay of 15 seconds assumes a maximum network size of seven bridge hops, a maximum of three lost BPDUs and a hello-interval of 2 seconds.

For an active-active HA cluster to be compatible with the spanning tree algorithm, the FGCP requires that the sum of maximum age and forward delay should be less than 20 seconds. The maximum age and forward delay settings are designed to prevent layer 2 loops. If there is no possibility of layer 2 loops in the network, you could reduce the forward delay to the minimum value.

For some Dell 3348 switches the default maximum age is 20 seconds and the default forward delay is 15 seconds. In this configuration the switch cannot work with a FortiGate HA cluster. However, the switch and cluster are compatible if the maximum age is reduced to 10 seconds and the forward delay is reduced to 5 seconds.

Spanning Tree protocol (STP)

Spanning tree protocol is an IEEE 802.1 standard link management protocol that for media access control bridges. STP uses the spanning tree algorithm to provide path redundancy while preventing undesirable loops in a network that are created by multiple active paths between stations. Loops can be created if there are more than route between two hosts. To control path redundancy, STP creates a tree that spans all of the switches in an extended network. Using the information in the tree, the STP can force redundant paths into a standby, or blocked, state. The result is that only one active path is available at a time between any two network devices (preventing looping). Redundant links are used as backups if the initial link should fail. Without spanning tree in place, it is possible that two connections may be simultaneously live, which could result in an endless loop of traffic on the network.

Bridge Protocol Data Unit (BPDU)

BPDUs are spanning tree data messages exchanged across switches within an extended network. BPDU packets contain information on ports, addresses, priorities and costs and ensure that the data ends up where it was intended to go. BPDU messages are exchanged across bridges to detect loops in a network topology. The loops are then removed by shutting down selected bridge interfaces and placing redundant switch ports in a backup, or blocked, state.

Failover and attached network equipment

It normally takes a cluster approximately 6 seconds to complete a failover. However, the actual failover time may depend on how quickly the switches connected to the cluster interfaces accept the cluster MAC address update from the primary unit. If the switches do not recognize and accept the gratuitous ARP packets and update their MAC forwarding table, the failover time will increase.

Also, individual session failover depends on whether the cluster is operating in active-active or active-passive mode, and whether the content of the traffic is to be virus scanned. Depending on application behavior, it may take a TCP session a longer period of time (up to 30 seconds) to recover completely.

Ethertype conflicts with third-party switches

Some third-party network equipment may use packets with Ethertypes that are the same as the ethertypes used for HA heartbeat packets. For example, Cisco N5K/Nexus switches use Ethertype 0x8890 for some functions. When one of these switches receives Ethertype 0x8890 heartbeat packets from an attached cluster unit, the switch generates CRC errors and the packets are not forwarded. As a result, FortiGate units connected with these switches cannot form a cluster.

In some cases, if the heartbeat interfaces are connected and configured so regular traffic flows but heartbeat traffic is not forwarded, you can change the configuration of the switch that connects the HA heartbeat interfaces to allow level2 frames with Ethertypes 0x8890, 0x8891, and 0x8893 to pass.

You can also use the following CLI commands to change the Ethertypes of the HA heartbeat packets:

```
config system ha
   set ha-eth-type <ha_ethertype_4-digit_hex>
   set hc-eth-type <hc_ethertype_4-digit_hex>
   set l2ep-eth-type <l2ep_ethertype_4-digit_hex>
end
```

For more information, see Heartbeat packet Ethertypes on page 1461.

LACP, 802.3ad aggregation and third-party switches

If a cluster contains 802.3ad aggregated interfaces you should connect the cluster to switches that support configuring multiple Link Aggregation (LAG) groups.

The primary and subordinate unit interfaces have the same MAC address, so if you cannot configure multiple LAG groups a switch may place all interfaces with the same MAC address into the same LAG group; disrupting the operation of the cluster.

You can change the FortiGate configuration to prevent subordinate units from participating in LACP negotiation. For example, use the following command to do this for an aggregate interface named Port1_Port2:

```
config system interface
   edit Port1_Port2
      set lacp-ha-slave disable
   end
```

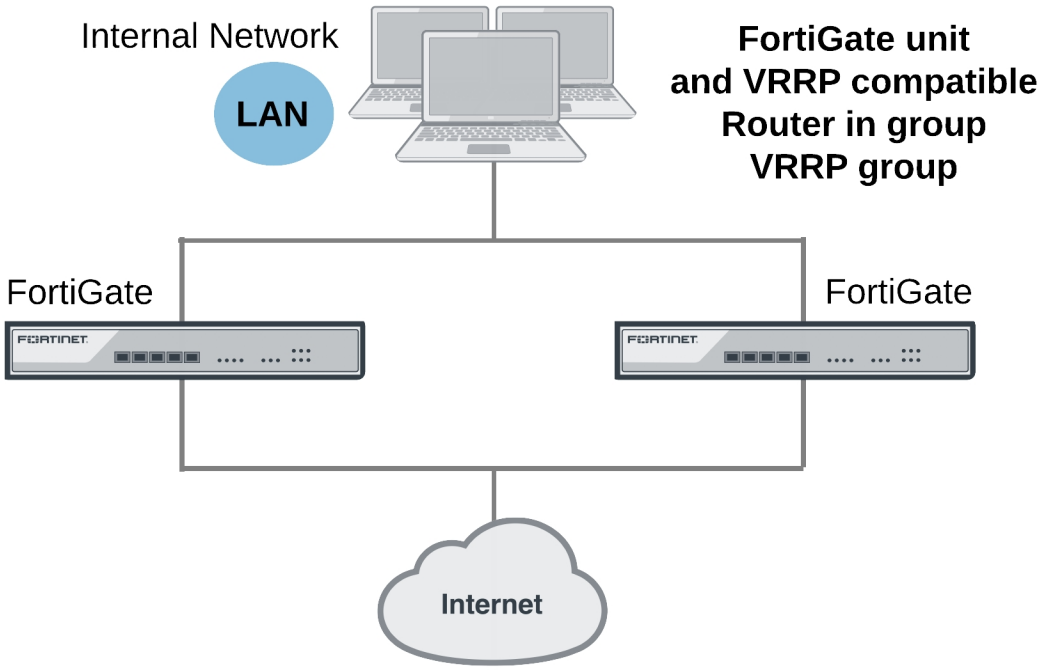
This configuration prevents the subordinate unit interfaces from sending or receiving packets. Resulting in the cluster not being able to operate in active-active mode. As well, failover may be slower because after a failover the new primary unit has to perform LACP negotiation before being able to process network traffic.

For more information, see Example: FGCP configuration examples and troubleshooting on page 1313.

VRRP

A Virtual Router Redundancy Protocol (VRRP) configuration can be used as a high availability solution to make sure that a network maintains connectivity with the Internet (or with other networks) even if the default router for the network fails. Using VRRP, if a router or a FortiGate unit fails all traffic to this router transparently fails over to another router or FortiGate unit that takes over the role of the router or FortiGate unit that failed. If the failed router or FortiGate unit is restored, it will once again take over processing traffic for the network. VRRP is described by RFC 3768.

Example VRRP configuration



To configure VRRP you create a VRRP group that contains two or more routers. Some or all of these routers can be FortiGate units. You can include different FortiGate models in the same VRRP group. The group members are configured to be the master router and one or more backup routers of the VRRP group. The network directs all traffic to the master's IP address and MAC address. If the master fails, VRRP dynamically shifts packet forwarding to a backup router. VRRP provides this redundancy without user intervention or additional configuration to any of the devices on the network.

The VRRP redundancy scheme means that devices on the network keep a single IP address for the default gateway and this IP address maps to a well-known virtual MAC address. If the VRRP master fails, one of the backup units becomes the new master and acquires virtual IP and MAC addresses that match the addresses of the master. The network then automatically directs all traffic to the backup unit. VRRP uses the broadcast capabilities of Ethernet networks. A long as one of the routers in a VRRP group is running, ARP requests for the

default gateway IP address always receive replies. Additionally, hosts can send packets outside their subnet without interruption.

FortiGate units support VRRP and can be quickly and easily integrated into a network that has already deployed a group of routers using VRRP. You can also create a new VRRP configuration consisting of a FortiGate unit acting as a VRRP master with one or more VRRP-compatible routers acting as backup routers. Some or all of those backup routers can be FortiGate units.

During normal operation the VRRP master unit sends VRRP advertisement messages to the backup units. A backup unit will not attempt to become a master unit while it is receiving these messages. When a FortiGate unit operating as a VRRP master fails, a backup unit takes its place and continues processing network traffic. The backup unit assumes the master unit has failed if it stops receiving the advertisement messages from the master unit. The backup unit with the highest priority becomes the new master unit after a short delay. During this delay the new master unit sends gratuitous ARPs to the network to map the virtual router IP address it its MAC address. As a result, all packets sent to the default route IP address are sent the new master unit. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line.

During a VRRP failover, as the backup unit starts to forward traffic it will not have session information for all of the failed over in-progress sessions. If the backup unit is operating as a normal FortiGate unit it will not be able to forward this traffic because of the lack of session information. To resolve this problem, immediately after a failover and for a short time as its taking over traffic processing, the backup unit operates with asymmetric routing enabled. This allows the backup unit to re-create all of the in-progress sessions and add them to the session table. While operating with asymmetric routing enabled, the backup unit cannot apply security functions. When the start-time ends the backup unit disables asymmetric routing and returns to normal operation including applying security functions.

Adding a VRRP virtual router to a FortiGate interface

Use the following command to add a VRRP virtual router to the port10 interface of a FortiGate unit. This VRRP virtual router has a virtual router ID of 200, uses IP address 10.31.101.200 and has a priority of 255. Since this is the highest priority this interface is configured to be the master of the VRRP group with ID number 200.

VRRP can be configured only on physical interfaces or VLAN interfaces. You cannot configure VRRP on hardware-switch interfaces where multiple physical interfaces are combined into a hardware switch interface.

```
config system interface
   edit port10
      config vrrp
         edit 200
            set vrip 10.31.101.200
            set priority 255
         end
   end
```

VRRP virtual MAC address

The VRRP virtual MAC address (or virtual router MAC address) is a shared MAC address adopted by the VRRP master. If the master fails the same virtual MAC master fails over to the new master. As a result, all packets for

VRRP routers can continue to use the same virtual MAC address. You must enable the VRRP virtual MAC address feature on all members of a VRRP group.

Each VRRP router is associated with its own virtual MAC address. The last part of the virtual MAC depends on the VRRP virtual router ID using the following format:

```
00-00-5E-00-01-<VRID_hex>
```

Where <VRID_hex> is the VRRP virtual router ID in hexadecimal format in internet standard bit-order. For more information about the format of the virtual MAC see RFC 3768.

Some examples:

- If the VRRP virtual router ID is 10 the virtual MAC would be 00-00-5E-00-01-0a.
- If the VRRP virtual router ID is 200 the virtual MAC would be 00-00-5E-00-01-c8.

The VRRP virtual MAC address feature is disabled by default. Wen you enable the feature on a FortiGate interface, all of the VRRP routers added to that interface use their own VRRP virtual MAC address. Each virtual MAC address will be different because each virtual router has its own ID.

Use the following command to enable the VRRP virtual MAC address on the port2 interface:

```
config system interface
   edit port2
      set vrrp-virtual-mac enable
   end
end
```

The port2 interface will now accept packets sent to the MAC addresses of the VRRP virtual routers added to this interface.

Using the VRRP virtual MAC address can improve network efficiency especially on large and complex LANs because when a failover occurs devices on the LAN do not have to learn a new MAC address for the new VRRP router.

If the VRRP virtual MAC address feature is disabled, the VRRP group uses the MAC address of the master. In the case of a FortiGate VRRP virtual router this is the MAC address of the FortiGate interface that the VRRP virtual routers are added to. If a master fails, when the new master takes over it sends gratuitous ARPs to associate the VRRP virtual router IP address with the MAC address of the new master (or the interface of the FortiGate unit that has become the new master). If the VRRP virtual MAC address is enabled the new master uses the same MAC address as the old master.

VRRP Groups

A VRRP group includes all the relevant VRRP IDs and tracks the VRRP status to force the status of all group members if a VRRP domain is changed from master to backup. VRRP groups are configured through the CLI. The VRRP group ID can be between 1 and 65535. Use the following command to add a VRRP group to the port20 interface that includes the virtual route identifiers 25, 50, 66 and 70 to VRRP group 10

```
config system interface
   edit port20
      config vrrp
         edit 25
            set vrgrp 10
         next
         edit 50
            set vrgrp 10
         next
         edit 66
            set vrgrp 10v
```

```
        next
        edit 70
           set vrgrp 10
    end
```

Using a Second Destination IP (VRDST)

VRRP can now be configured with second destination IP (VRDST) for monitoring. When two IPs are used, VRRP failure will only be reported if both monitored IPs are down.

Use the following command to configure a second destination IP (VRDST) to port14:

```
config system interface
   edit port14
      config vrrp
         edit 12
            set vrdst 10.10.10.20 10.20.20.10
      end
```

Configuring VRRP

To configure VRRP you must configure two or more FortiGate interfaces or routers with the same virtual router ID and IP address. Then these FortiGate units or routers can automatically join the same VRRP group. You must also assign priorities to each of the FortiGate units or routers in the VRRP group. One of the FortiGate units or routers must have the highest priority to become the master. The other FortiGate units or routers in the group are assigned lower priorities and become backup units. All of the units in the VRRP group should have different priorities. If the master unit fails, VRRP automatically fails over to the remaining unit in the group with the highest priority.

You configure VRRP from the FortiGate CLI by adding a VRRP virtual router to a FortiGate interface. You can add VRRP virtual routers to multiple FortiGate interfaces and you can add more than one virtual router to the same interface.

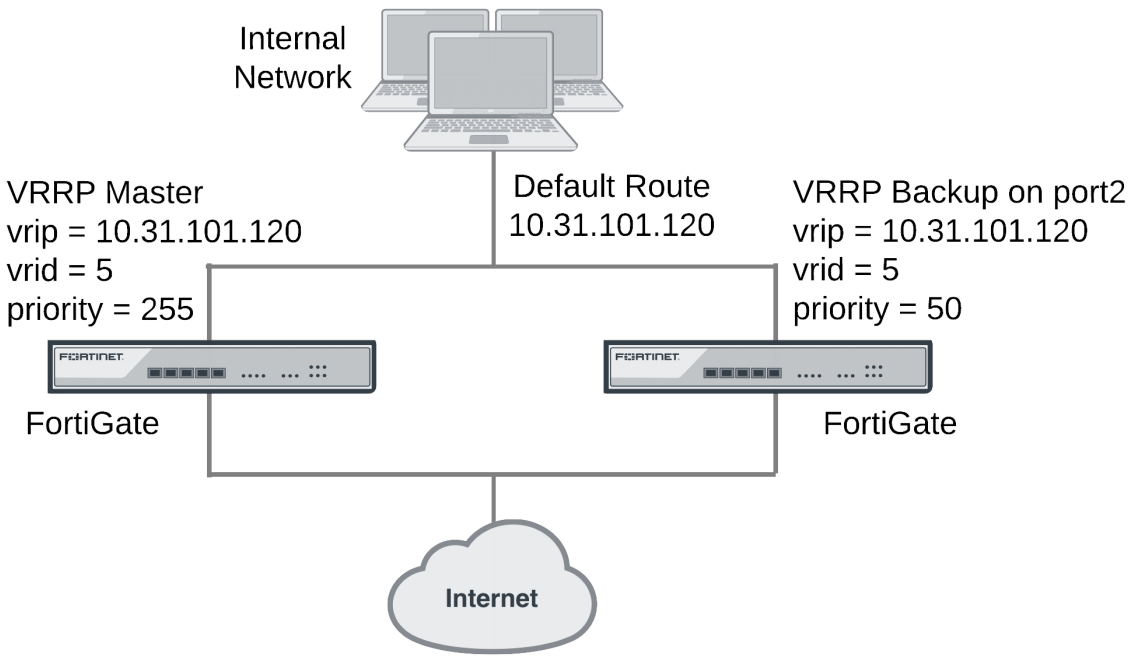
Example VRRP configuration: two FortiGate units in a VRRP group

This example includes a VRRP group consisting of two FortiGate units that connect an internal network to the Internet. As shown below, the internal network's default route is 10.31.101.120.

The FortiGate port2 interfaces connect to the internal network. A VRRP virtual router is added to each FortiGate unit's port2 interface. The virtual router IP address is 10.31.101.120 (the internal network's default route) and the virtual router's ID is 5. The VRRP priority of the master unit is set to 255 and the VRRP priority of the backup unit is 50. The port2 interface of each FortiGate unit should have an IP address that is different from the virtual router IP address and the port2 interface IP addresses should be different from each other.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP group uses the VRRP virtual MAC address.

Example VRRP configuration with two FortiGate units



To configure the FortiGate units for VRRP

1. Select one of the FortiGate units to be the VRRP master and the other to be the backup unit.
2. From the master unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
   edit port2
   set vrrp-virtual-mac enable
      config vrrp
         edit 5
            set vrip 10.31.101.120
            set priority 255
         end
   end
```

3. From the backup unit's CLI, enter the following command to enable the VRRP virtual MAC address on the port2 interface and add the VRRP virtual router to the port2 interface:

```
config system interface
   edit port2
      set vrrp-virtual-mac enable
      config vrrp
         edit 5
            set vrip 10.31.101.120
            set priority 50
         end
   end
```

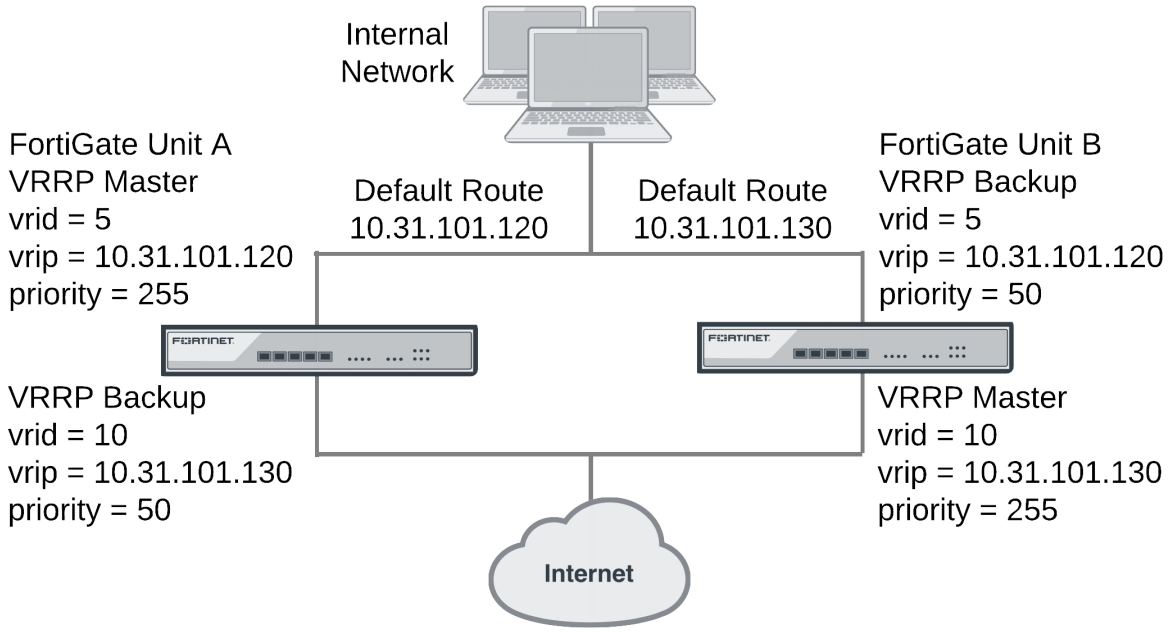
Example VRRP configuration: VRRP load balancing two FortiGate units and two VRRP groups

In this configuration two VRRP groups are involved. Each FortiGate unit participates in both of them. One FortiGate unit is the master of one group and the other FortiGate unit is the master of the other group. The network distributes traffic between two different default routes (10.31.101.120 and 10.31.101.130). One VRRP group is configured with one of the default route IP addresses and the other VRRP group get the other default route IP address. So during normal operation both FortiGate units are processing traffic and the VRRP groups are used to load balance the traffic between the two FortiGate units.

If one of the FortiGate units fails, the remaining FortiGate unit becomes the master of both VRRP groups. The network sends all traffic for both default routes to this FortiGate unit. The result is a configuration that under normal operation load balances traffic between two FortiGate units, but if one of the FortiGate units fails, all traffic fails over to the unit that is still operating.

This example also includes enabling the VRRP virtual MAC address on both FortiGate unit port2 interfaces so that the VRRP groups use their VRRP virtual MAC addresses.

Example VRRP configuration with two FortiGate units and two VRRP groups



To configure the FortiGate units

1. Log into the CLI of FortiGate unit A.
2. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit A:

```
config system interface
   edit port2
      set vrrp-virtual-mac enable
```

```
      config vrrp
         edit 50 (32)
            set vrip 10.31.101.120
            set priority 255
         next
         edit 100 (64)
            set vrip 10.31.101.130
            set priority 50
         end
   end
```

3. Log into the CLI of FortiGate unit B.
4. Enter the following command to enable the VRRP virtual MAC address feature and add the VRRP groups to the port2 interface of FortiGate unit B:

```
config system interface
   edit port2
      set vrrp-virtual-mac enable
      config vrrp
         edit 50
            set vrip 10.31.101.120
            set priority 50
         next
         edit 100
            set vrip 10.31.101.130
            set priority 255
         end
   end
```

Optional VRRP configuration settings

In addition to the basic configuration settings, you can change to the VRRP configuration to:

- Adjust the virtual router advertisement message interval between 1 and 255 seconds using the `adv-interval` option.
- Adjust the startup time using the `start-time` option. The default start time is 3 seconds and the range is 1 to 255 seconds. The start time is the maximum time that the backup unit waits between receiving advertisement messages from the master unit. If the backup unit does not receive an advertisement message during this time it assumes the master has failed and becomes the new master unit. In some cases the advertisement messages may be delayed. For example, some switches with spanning tree enabled may delay some of the advertisement message packets. If you find that backup units are attempting to become master units without the master unit failing, you can extend the start time to make sure the backup units wait long enough for the advertisement messages.
- Enable or disable individual virtual router configurations using the `status` option. Normally virtual router configurations are enabled but you can temporarily disable one if its not required.
- Enable or disable preempt mode using the `preempt` option. In preempt mode a higher priority backup unit can preempt a lower priority master unit. This can happen if a master has failed, a backup unit has become the master unit, and the failed master is restarted. Since the restarted unit will have a higher priority, if preempt mode is enabled the restarted unit will replace the current master unit. Preempt mode is enabled by default.
- Monitor the route to a destination IP address using the `vrdst` option.

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGate units can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGate units and the FGSP performs session synchronization of IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGate units synchronized.

You can use the `config system session-sync` command to configure the FortiGate Session Life Support Protocol (FGSP) (previously called TCP session synchronization or standalone session synchronization) between two FortiGate units. The two FortiGate units must be the same model. The FGSP synchronizes both IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions. You can use this feature with external routers or load balancers configured to distribute or load balance sessions between two peer FortiGate units. If one of the peers fails, session failover occurs and active sessions fail over to the peer that is still operating. This failover occurs without any loss of data. As well, the external routers or load balancers will detect the failover and re-distribute all sessions to the peer that is still operating.

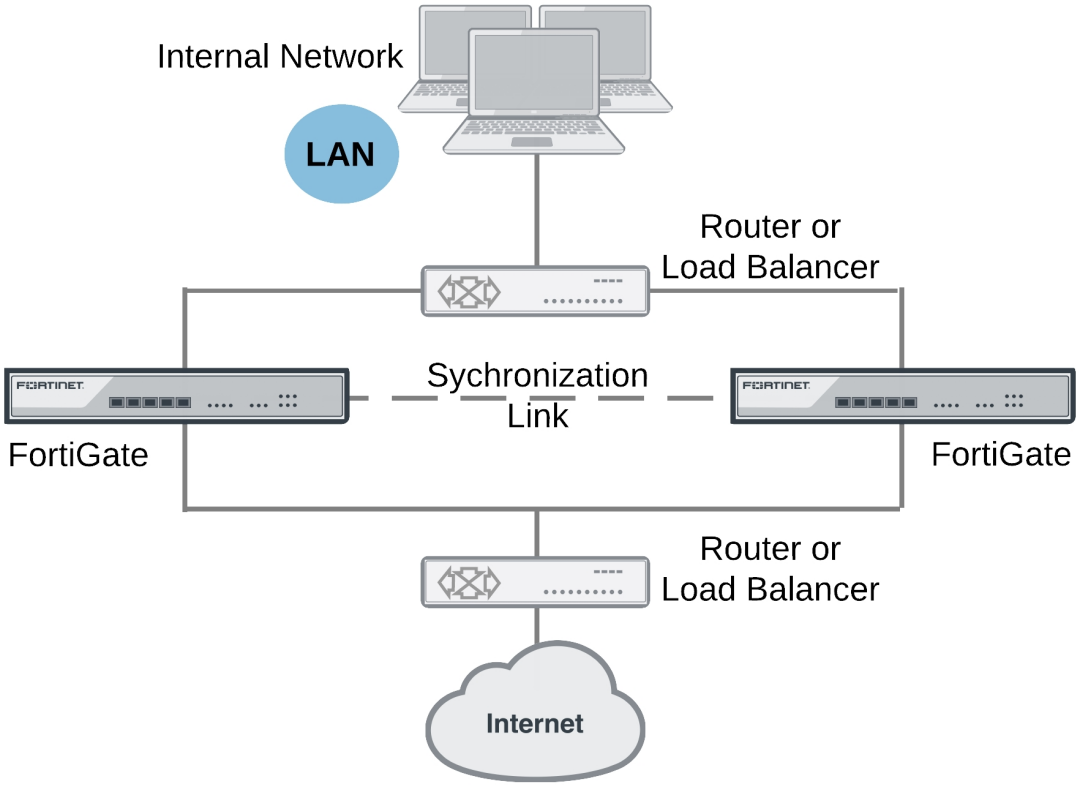
In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

You cannot configure FGSP HA when FGCP HA is enabled. However FGSP HA is compatible with VRRP.

FGSP or standalone session synchronization is not supported if the FortiGate units are running different firmware versions.

The FGSP can be used instead of FGCP HA to provide **session synchronization** between two peer FortiGate units. If the external load balancers direct all sessions to one peer the affect is similar to active-passive FGCP HA. If external load balancers or routers load balance traffic to both peers, the effect is similar to active-active FGCP HA. The load balancers should be configured so that all of the packets for any given session are processed by the same peer. This includes return packets.

FGSP HA



By default, FGSP synchronizes all IPv4 and IPv6 TCP sessions and also synchronizes the configuration of the FortiGate units.

You can optionally enable session pickup to synchronize connectionless (UDP and ICMP) sessions, expectation sessions, and NAT sessions. If you do not enable session pickup, the FGSP does not share session tables for the particular session type and sessions do not resume after a failover. All sessions that are interrupted by the failover and must be re-established at the application level. Many protocols can successfully restart sessions with little, or no, loss of data. Others may not recover easily. Enable session pickup for sessions that may be difficult to reestablish. Since session pickup requires FortiGate resources, only enable this feature for sessions that you need to have synchronized.

You can also optionally add filters to control which sessions are synchronized. You can add filters to only synchronize packets from specified source and destination addresses, specified source and destination interfaces, and specified services.

Load balancing and session failover is done by external routers or load balancers instead of by the FGSP. The FortiGate units just perform session synchronization to support session failover.

Synchronizing the configuration

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGate units instead of requiring you to make duplicate configuration changes on each FortiGate unit. Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate unit maintains its identity on the network.

By default configuration synchronization is disabled. You can use the following command to enable it.

```
config system ha
   set standalone-config-sync enable
end
```

Synchronizing UDP and ICMP (connectionless) sessions

In many configurations, due to their non-stateful nature, UDP and ICMP sessions don't need to be synchronized to naturally failover. However, if its required you can configure the FGSP to synchronize UDP and ICMP sessions by entering the following command:

```
config system ha
   set session-pickup enable
   set session-pickup-connectionless enable
end
```

Synchronizing NAT sessions

By default, NAT session are not synchronized. However, the FGSP can synchronize NAT session if you enter the following command:

```
config system ha
   set session-pickup enable
   set session-pickup-nat enable
end
```

However, if you want NAT sessions to resume after a failover you should not configure NAT to use the destination interface IP address since the FGSP FortiGate units have different IP addresses. With this configuration, after a failover all sessions that include the IP addresses of interfaces on the failed FortiGate unit will have nowhere to go since the IP addresses of the failed FortiGate unit will no longer be on the network.

Instead, in an FGSP configuration, if you want NAT sessions to failover you should use IP pools with the type set to overload (which is the default IP pool type). For example:

```
config firewall ippool
   edit FGSP-pool
      set type overload
      set startip 172.20.120.10
      set endip 172.20.120.20
   end
```

Then when you configure NAT firewall policies, turn on NAT and select to use dynamic IP pool and select the IP Pool that you added. Add the same IP pools and firewall policies to both FortiGate units.

Synchronizing asymmetric sessions

By default, asymmetric sessions are not synchronized. Normally, session synchronization cannot be asymmetric because it is stateful. So all of the packets of a given session must be processed on the same peer. This includes return packets.

However, if you have an asymmetric routing configuration, you can enter the following command to synchronize asymmetric sessions by dynamically detecting asymmetric sessions and disabling anti-reply for these sessions.

```
config system ha
   set session-pickup enable
   set session-pickup-expectation enable
end
```

The FGSP enforces firewall policies for asymmetric traffic, including cases where the TCP 3-way handshake is split between two FortiGates. For example, FGT-A receives the TCP-SYN, FGT-B receives the TCP-SYN-ACK, and FGT-A receives the TCP-ACK. Under normal conditions a firewall will drop this connection since the 3-way handshake was not seen by the same firewall. However two FortiGates with FGSP configured will be able to properly pass this traffic since the firewall sessions are synchronized.

This asymmetric function can also work with connectionless UDP and ICMP traffic. If traffic will be highly asymmetric, as described above, the following command must be enabled on both FortiGates.

```
config system ha
   set session-pickup enable
   set session-pickup-connectionless enable
end
```

Synchronizing asymmetric traffic can be very useful in situations where multiple Internet connections from different ISPs are spread across two FortiGates. Since it is typically not possible to guarantee Internet bound traffic leaving via an ISP will return using the exact same ISP, the FGSP provides critical firewall functions in this situation.

Asymmetric sessions may not be synchronized in low latency networks if the reply packet is received before the peer has received the session synchronization packet. This limitation usually only occurs in low latency networks.

The FGSP also has applications in virtualized computing environments where virtualized hosts move between data centers. The firewall session synchronization features of FGSP allow for more flexibility than in traditional firewalling functions.

Synchronizing expectation sessions

FortiOS session helpers keep track of the communication of Layer-7 protocols such as FTP and SIP that have control sessions and expectation sessions. Usually the control sessions establish the link between server and client and negotiate the ports and protocols that will be used for data communications. The session helpers then create expectation sessions through the FortiGate for the ports and protocols negotiated by the control session.

The expectation sessions are usually the sessions that actually communicate data. For FTP, the expectation sessions transmit files being uploaded or downloaded. For SIP, the expectation sessions transmit voice and video data. Expectation sessions usually have a timeout value of 30 seconds. If the communication from the server is not initiated within 30 seconds the expectation session times out and traffic will be denied.

By default the FGSP does not synchronize expectation sessions and if a failover occurs the sessions will have to be restarted.

If you want to synchronize expectation sessions so that they will continue after a failover you can enter the following command on both FortiGates to synchronize them:

```
config system ha
   set session-pickup enable
   set session-pickup-expectation enable
end
```

Security profile flow-based inspection and asymmetric traffic

Security profile inspection (flow or proxy based) for a session is not expected to work properly if the traffic in the session is balanced across more than one FortiGate in either direction. Flow-based inspection should be used in

FGSP deployments.

For an environment where traffic is symmetric, security profile inspection can be used with the following limitations:

- No session synchronization for the sessions inspected using proxy-based inspection. Sessions will drop and need to be reestablished after data path failover.
- Sessions with flow-based inspection will failover; however, inspection of failed over sessions after the failover may not work.

A single FortiGate must see both the request and reply traffic for security profile inspection to function correctly. For environments where asymmetric traffic is expected, security profile inspection should not be used.

Notes and limitations

FGSP HA has the following limitations:

- The FGSP is a global configuration option. As a result you can only add one service to a filter configuration. You cannot add custom services or service groups even if virtual domains are not enabled.
- You can only add one filter configuration to a given FGSP configuration. However, you can add multiple filters by adding multiple identical FGSP configurations, each one with a different filter configuration.
- Sessions accepted by security policies with security profiles configured are not synchronized.
- FGSP HA is configured from the CLI.
- FGSP HA is available for FortiGate units or virtual domains operating in NAT/Route or Transparent mode. NAT sessions are not synchronized in either mode (unless NAT synchronization is enabled as described in Synchronizing NAT sessions on page 1538). In NAT/Route mode, only sessions for route mode security policies are synchronized. In Transparent mode, only sessions for normal Transparent mode policies are synchronized.
- FGSP HA is supported for traffic on physical interfaces, VLAN interfaces, zones, aggregate interfaces, and NPx (NP4, NP6 etc.) accelerated interfaces. The FGSP has not been tested for inter-vdom links, between HA clusters, and for redundant interfaces.
- The names of the matching interfaces, including VLAN interfaces, aggregate interfaces and so on, must be the same on both peers.

Configuring FGSP HA

You configure FGSP HA separately for each virtual domain to be synchronized. If virtual domain configuration is not enabled, you configure FGSP HA for the root virtual domain. When virtual domain configuration is enabled and you have added virtual domains you configure FGSP HA for each virtual domain to be synchronized. You don't have to synchronize all virtual domains.

You must configure FGSP HA and network settings on both peers. Once you establish the initial configuration, the configurations of both FortiGate units are synchronized so when you change the configuration of one, the changes are synchronized to the other.

On each FortiGate unit, configuring FGSP HA consists of selecting the virtual domains to be synchronized using the `syncvd` field, selecting the virtual domain on the other peer that receives the synchronization packets using the `peervd` field, and setting the IP address of the interface in the peer unit that receives the synchronization packets using the `peerip` field. The interface with the `peerip` must be in the `peervd` virtual domain.

The `syncvd` and `peervd` settings must be the same on both peers. However, the `peerip` settings will be different because the `peerip` setting on the first peer includes the IP address of an interface on the second peer. And the `peerip` setting on the second peer includes the IP address of an interface on the first peer.

For FGSP HA to work properly all synchronized virtual domains must be added to both peers. The names of the matching interfaces in each virtual domain must also be the same; this includes the names of matching VLAN interfaces. Note that the index numbers of the matching interfaces and VLAN interfaces can be different. Also the VLAN IDs of the matching VLAN interfaces can be different.

Configuring the session synchronization link

When FGSP HA is operating, the peers share session information over an Ethernet link between the peers similar to an HA heartbeat link. Usually you would use the same interface on each peer for session synchronization. You should connect the session synchronization interfaces directly without using a switch or other networking equipment. For FortiGate-5000 systems you can use a backplane interface as the session synchronization link.

You can use different interfaces on each peer for session synchronization links. Also, if you have multiple sessions synchronization configurations, you can have multiple links between the peers. In fact if you are synchronizing a lot of sessions, you may want to configure and connect multiple session synchronization links to distribute session synchronization traffic to these multiple links.

You cannot configure backup session synchronization links. Each configuration only includes one session synchronization link.

The session synchronization link should always be maintained. If session synchronization communication is interrupted and a failure occurs, sessions will not failover and data could be lost.

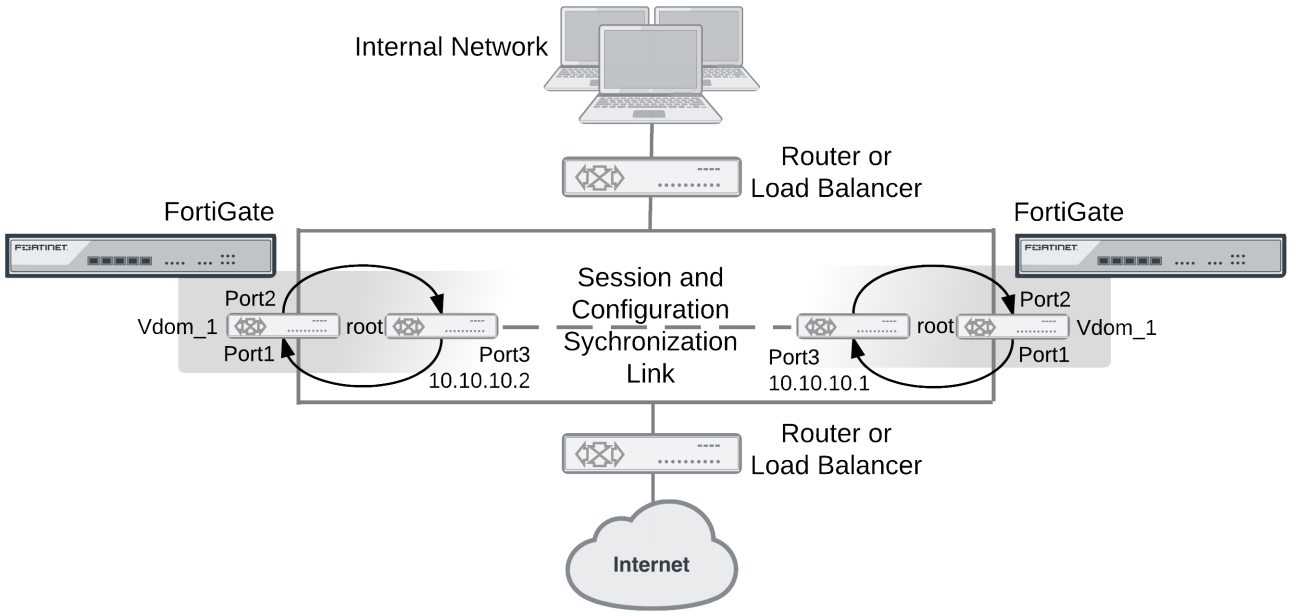
Session synchronization traffic can use a considerable amount of network bandwidth. If possible, session synchronization link interfaces should only be used for session synchronization traffic and not for data traffic.

Basic example configuration

The following configuration example shows how to configure basic FGSP HA for the two peer FortiGate units shown below. The host names of peers are peer_1 and peer_2. Both peers are configured with two virtual domains: root and vdom_1. All sessions processed by vdom_1 are synchronized. The synchronization link interface is port3 which is in the root virtual domain. The IP address of port3 on peer_1 is 10.10.10.1. The IP address of port3 on peer_2 is 10.10.10.2.

Also on both peers, port1 and port2 are added to vdom_1. On peer_1 the IP address of port1 is set to 192.168.20.1 and the IP address of port2 is set to 172.110.20.1. On peer_2 the IP address of port1 is set to 192.168.20.2 and the IP address of port2 is set to 172.110.20.2.

Example FGSP HA network configuration



To configure FGSP HA

1. Configure the load balancer or router to send all sessions to peer_1.
2. Configure the load balancer or router to send all traffic to peer_2 if peer_1 fails.
3. Use normal FortiGate configuration steps on peer_1:
   - Enable virtual domain configuration.
   - Add the vdom_1 virtual domain.
   - Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
   - Set the IP address of port1 to 192.168.20.1.
   - Set the IP address of port2 to 172.110.20.1.
   - Set the IP address of port3 to 10.10.10.1.
   - Add route mode security policies between port1 and port2 to vdom_1.
4. Enter the following commands to configure session synchronization for peer_1

```
config system session-sync
   edit 1
      set peerip 10.10.10.2
      set peervd root
      set syncvd vdom_1
end
```

5. Use normal FortiGate configuration steps on peer_2:
   - Enable virtual domain configuration.
   - Add the vdom_1 virtual domain.
   - Add port1 and port2 to the vdom_1 virtual domain and configure these interfaces.
   - Set the IP address of port1 to 192.168.20.2.
   - Set the IP address of port2 to 172.110.20.2.
   - Set the IP address of port3 to 10.10.10.1.
   - Add route mode security policies between port1 and port2 to vdom_1.
6. Enter the following command to configure session synchronization for peer_1

```
config system session-sync
   edit 1
      set peerip 10.10.10.1
      set peervd root
      set syncvd vdom_1
end
```

Now that the FortiGate units are connected and configured their configurations are synchronized, so when you make a configuration change on one FortiGate unit it is synchronized to the other one.

To add filters

You can add a filter to this basic configuration if you only want to synchronize some TCP sessions. For example you can enter the following command to add a filter so that only HTTP sessions are synchronized:

```
config system session-sync
   edit 1
      config filter
         set service HTTP
      end
end
```

You can also add a filter to control the source and destination addresses of the IPv4 packets that are synchronized. For example you can enter the following command to add a filter so that only sessions with source addresses in the range 10.10.10.100 to 10.10.10.200 are synchronized.

```
config system session-sync
   edit 1
      config filter
         set srcaddr 10.10.10.100 10.10.10.200
      end
end
```

You can also add a filter to control the source and destination addresses of the IPv6 packets that are synchronized. For example you can enter the following command to add a filter so that only sessions with destination addresses in the range 2001:db8:0:2::/64 are synchronized.

```
config system session-sync
   edit 1
      config filter
         set dstaddr6 2001:db8:0:2::/64
      end
end
```

To synchronize UDP and ICMP sessions

You enter the following command to add synchronization of UDP and ICMP sessions to this configuration:

```
config system ha
   set session-pickup enable
   set session-pickup-connectionless enable
end
```

To synchronize the configuration

Enter the following command to enable configuration synchronization.

```
config system ha
   set standalone-config-sync enable
end
```

Verifying FGSP configuration and synchronization

You can use the following diagnose commands to verify that the FGSP and its synchronization functions are operating correctly.

FGSP configuration summary and status

Enter the following command to display a summary of the FGSP configuration and synchronization status:

```
diagnose sys session sync
sync_ctx: sync_started=1, sync_tcp=1, sync_others=1,
sync_expectation=1, sync_redir=0, sync_nat=1.
sync: create=12:0, update=0, delete=0:0, query=14
recv: create=14:0, update=0, delete=0:0, query=12
ses pkts: send=0, alloc_fail=0, recv=0, recv_err=0 sz_err=0
nCfg_sess_sync_num=5, mtu=16000
sync_filter:
1: vd=0, szone=0, dzone=0, saddr=0.0.0.0:0.0.0.0, daddr=0.0.0.0:0.0.0.0,
```

`sync_started=1` shows that synchronization is working. If this is set to 0 then something is not correct with session synchronization and synchronization has not been able to start because of it.

`sync_tcp=1`, `sync_others=1`, `sync_expectation=1`, and `sync_nat=1` show that the FGSP has been configured to synchronize TCP, connectionless, asymmetric, and NAT sessions.

`sync: create=12:0` and `recv: create=14:0` show that this FortiGate has synchronized 12 sessions to its peer and has received 14 sessions from its peer.

`sync_filter` shows the configured FGSP filter. In this case no filter has been created so all sessions are synchronized.

`vd=0` indicates that root VDOM sessions are synchronized.

Verifying that sessions are synchronized

Enter the command `diagnose sys session list` to display information about the sessions being processed by the FortiGate. In the command output look for sessions that should be synchronized and make sure they contain output lines that include `synced` (for example, `state=log may_dirty ndr synced`) to confirm that they are being synchronized by the FGSP.

```
diagnose sys session list
session info: proto=6 proto_state=05 duration=469 expire=0 timeout=3600
flags=00000000 sockflag=00000000 sockport=21 av_idx=0 use=4
origin-shaper=
```

```
reply-shaper=
per_ip_shaper=
ha_id=0 policy_dir=0 tunnel=/
state=log may_dirty ndr synced
statistic(bytes/packets/allow_err): org=544/9/1 reply=621/7/0 tuples=2
orgin->sink: org pre->post, reply pre->post dev=46->45/45->46
gwy=10.2.2.1/10.1.1.1
hook=pre dir=org act=noop 192.168.1.50:45327->172.16.1.100:21(0.0.0.0:0)
hook=post dir=reply act=noop 172.16.1.100:21->192.168.1.50:45327(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=1 id_policy_id=0 auth_info=0 chk_client_info=0 vd=0
serial=00002deb tos=ff/ff ips_view=1 app_list=2000 app=16427
dd_type=0 dd_mode=0
per_ip_bandwidth meter: addr=192.168.1.50, bps=633
```

Configuring FRUP

The FortiGate Redundant UTM Protocol (FRUP) provides similar redundancy to FGCP full mesh HA in a single unified design that includes redundant switching and routing. FRUP is available on the FortiGate-100D and will be expanded to other models in future releases.

A FRUP cluster consists of 2 (and only 2) identical FortiGate-100D units that have dual redundant links to all connected devices and networks and can include redundant FortiAP units. Connections to the Internet normally use the wan1 and wan2 interfaces for redundant connections. Connections to internal networks and servers use redundant connections to FortiGate-100D switch ports. FRUP uses the FortiGate-100D switch ports for full mesh HA instead of external redundant switches.

Each device or network has a default active connection to one of the FortiGate units and a default backup connection to the other. Ideally, the default active and backup connections should balance traffic between the FortiGate units in the cluster so that both FortiGate units are processing the same amount of traffic.

FRUP uses virtual IPs and virtual MACs so that when a failover occurs, network devices do not have to learn new IP or MAC addresses. FRUP also synchronizes the configuration between the units in the cluster.

Use the following CLI command on both FortiGate-100D units to configure FRUP.

```
config system ha
   set hbdev "ha1" 50 "ha2" 100
   set override disable
   set priority 128
   set frup enable
      config frup-settings
         set active-interface "wan2"
         set active-switch-port 14
         set backup-interface "wan1"
      end
end
```

Both units must have the same heartbeat device configuration and have FRUP enabled to form a FRUP cluster. Active interface and switch ports must be complementary according to your configuration (see the following example).

FRUP and the mode of the FortiGate hardware switch

FRUP is only available when the FortiGate's internal hardware switch is configured to operate as a switch. You can determine the current internal switch mode using the following command:

```
get system status
...
Internal Switch Mode: switch
...
```

If `Internal Switch Mode` is set to `switch` the hardware switch is operating in the correct mode and you can configure FRUP. If Internal Switch Mode is set to `interface` or `hub` you need to enter the following command to set it to hardware switch mode:

```
config system global
   set internal-switch-mode switch
end
```

Before you can set the switch to hardware switch mode you need to remove all configuration settings that will be affected by this change. This includes firewall policies and DHCP servers. Also, if you have configured a software switch you must remove it. You can use the following command:

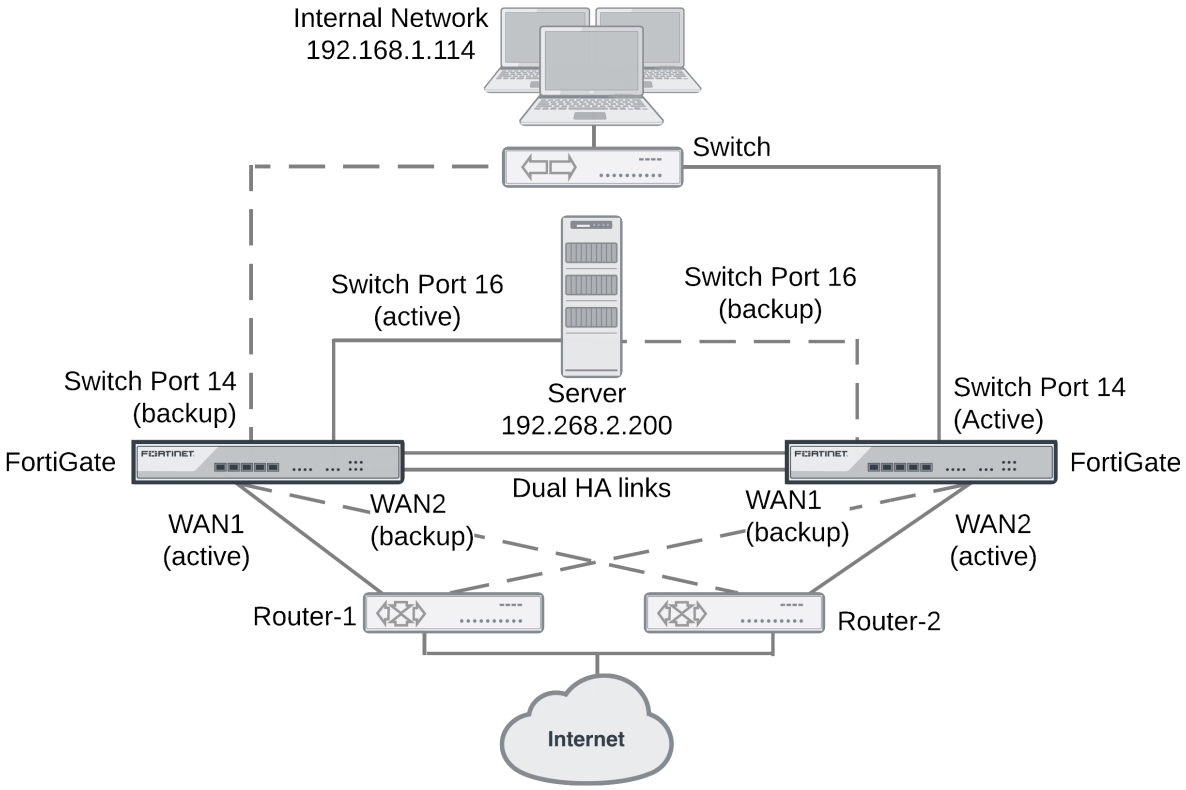
```
config system virtual-switch
   purge
end
```

FRUP configuration example

This example includes the following:

- Two FortiGate-100D units (FGT-A and FGT-B)
- HA1 and HA2 for redundant HA heartbeat connectivity between FGT-1 and FGT-2
- Dual gateways (router1 and router2):
  - FGT-A has an active connection from WAN1 to router-1 and a backup connection from WAN2 to router-2
  - FGT-B has an active connection from WAN2 to router-2 and a backup connection from WAN1 to router-1
- Dual connections to the internal network and an internal server:
  - FGT-A has an active connection to an internal server using switch port 16 and a backup connection to the internal network using switch port 14
  - FGT-B has a backup connection to an internal server using switch port 16 and an active connection to the internal network using switch port 14
- FortiGate interfaces use virtual IP addresses and pseudo-MAC physical addresses, all devices continue to send to the same IP/Mac and don't need to re-learn after a failover
- Both FortiGate units will handle and process traffic
- Backup links are normally administratively down
- Sessions and the FortiGate configuration are synchronized between the cluster units

Example FRUP configuration



Configuring FGT-A

Change the host name to FGT-A. Set up FGT-A with dual redundant internet links using WAN1 and WAN2. Set WAN1 and WAN2 interfaces to use static addressing and set both static routes to same priority and distance.

From CLI enter the following command:

```
config system ha
   set hbdev "ha1" 50 "ha2" 100
   set override disable
   set priority 255
   set frup enable
      config frup-settings
         set active-interface "wan1"
         set active-switch-port 16
         set backup-interface "wan2"
      end
   end
```

Configuring FGT-B

Use the same firmware version as FGT-A and set the FortiGate unit to factory defaults. Change the host name to FGT-B.

From CLI enter the following command:

```
config system ha
   set hbdev "ha1" 50 "ha2" 100
   set override disable
   set priority 128
   set frup enable
      config frup-settings
         set active-interface "wan2"
         set active-switch-port 14
         set backup-interface "wan1"
      end
   end
```

Connecting, testing and operating the FRUP cluster

Connect to the FortiGate-100D units to the network as shown in the diagram and power them on. The FortiGate-100D units should find each other and form a cluster.

Traffic from the server (IP: 192.168.1.200) connected to port16 should pass through FGT-A (since port16 is the active-switch-port in FGT-A) and to the Internet using WAN1 (since WAN1 is the active-interface in FGT-A).

Run a sniffer on both FortiGate units using the following command:

```
diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
```

Then run a ping to 4.2.2.2 from the server. The sniffer should show results similar to the following:

```
FGT-A # diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
0.231160 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
0.231202 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
0.231209 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.198520 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
1.198555 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
1.222569 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
1.222589 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.222595 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.199916 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
2.199952 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
2.232998 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
2.233017 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.233023 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.201347 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
3.201385 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
3.235406 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
3.235425 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
3.235430 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply

18 packets received by filter
0 packets dropped by kernel

FGT-A #
```

Traffic initiating from a host on the internal network (for example, IP: 192.168.1.114) connected to port14 should flow through FGT-B (since port14 is the active-switch-port in FGT-B) to the Internet using WAN2 (since WAN2 is FGT-B's active interface).

Run the same sniffer on both FortiGate units and then run a ping to 74.125.226.1 from the internal network. The sniffer should show results similar to the following:

```
FGT-B $ diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
1.887458 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
1.887488 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.887492 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.898137 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
1.898153 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.898159 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.885644 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
2.885682 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.885687 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.896175 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
2.896194 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
2.896201 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.884046 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
3.884091 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.884096 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
3.894192 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
3.894213 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
3.894220 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply

18 packets received by filter
0 packets dropped by kernel

FGT-B $
```

Shutdown FGT-A.

Traffic from the internal network should be handled by FGT-B using WAN1 and WAN2 interfaces:

```
FGT-B # diagnose sniffer packet any 'icmp' 4
interfaces=[any]
filters=[icmp]
0.954086 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
0.954226 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
0.968696 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
0.968780 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
0.968796 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.166934 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
1.166960 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.166966 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
1.177525 wan2 in 74.125.226.1 -> 172.20.120.130: icmp: echo reply
1.177541 internal out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.177547 eth1 out 74.125.226.1 -> 192.168.1.114: icmp: echo reply
1.955117 internal in 192.168.1.200 -> 4.2.2.2: icmp: echo request
1.955259 wan1 out 172.20.120.123 -> 4.2.2.2: icmp: echo request
1.987992 wan1 in 4.2.2.2 -> 172.20.120.123: icmp: echo reply
1.988084 internal out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
1.988101 eth1 out 4.2.2.2 -> 192.168.1.200: icmp: echo reply
2.165320 internal in 192.168.1.114 -> 74.125.226.1: icmp: echo request
2.165346 wan2 out 172.20.120.130 -> 74.125.226.1: icmp: echo request
2.165352 eth0 out 172.20.120.130 -> 74.125.226.1: icmp: echo request

```

To re-establish the cluster after a failover you need to restart both FortiGate-100D units. Just re-starting FGT-A may not bring the cluster back online.

Chapter 14 - IPsec VPN

This FortiOS Handbook chapter contains the following sections:

IPsec VPN concepts explains the basic concepts that you need to understand about virtual private networks (VPNs).

IPsec VPN overview provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

IPsec VPN in the web-based manager describes the IPsec VPN menu of the web-based manager interface.

Gateway-to-gateway configurations explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN. In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks.

Hub-and-spoke configurations describes how to set up hub-and-spoke IPsec VPNs. In a hub-and-spoke configuration, connections to a number of remote peers and/or clients radiate from a single, central FortiGate hub.

Dynamic DNS configuration describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a dynamic IP address and a domain name.

FortiClient dialup-client configurations guides you through configuring a FortiClient dialup-client IPsec VPN. In a FortiClient dialup-client configuration, the FortiGate unit acts as a dialup server and VPN client functionality is provided by the FortiClient Endpoint Security application installed on a remote host.

FortiGate dialup-client configurations explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit with a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

Supporting IKE Mode config clients explains how to set up a FortiGate unit as either an IKE Mode Config server or client. IKE Mode Config is an alternative to DHCP over IPsec.

Internet-browsing configuration explains how to support secure web browsing performed by dialup VPN clients, and hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

Redundant VPN configurations discusses the options for supporting redundant and partially redundant tunnels in an IPsec VPN configuration. A FortiGate unit can be configured to support redundant tunnels to the same remote peer if the FortiGate unit has more than one interface to the Internet.

Transparent mode VPNs describes two FortiGate units that create a VPN tunnel between two separate private networks transparently. In transparent mode, all FortiGate unit interfaces except the management interface are invisible at the network layer.

IPv6 IPsec VPNs describes FortiGate unit VPN capabilities for networks based on IPv6 addressing. This includes IPv4-over-IPv6 and IPv6-over-IPv4 tunnelling configurations. IPv6 IPsec VPNs are available in FortiOS 3.0 MR5 and later.

L2TP and IPsec (Microsoft VPN) explains how to support Microsoft Windows native VPN clients.

GRE over IPsec (Cisco VPN) explains how to interoperate with Cisco VPNs that use Generic Routing Encapsulation (GRE) protocol with IPsec.

Protecting OSPF with IPsec provides an example of protecting OSPF links with IPsec.

Redundant OSPF routing over IPsec provides an example of redundant secure communication between two remote networks using an OSPF VPN connection.

OSPF over dynamic IPsec provides an example of how to create a dynamic IPsec VPN tunnel that allows OSPF.

BGP over dynamic IPsec provides an example of how to create a dynamic IPsec VPN tunnel that allows BGP.

Phase 1 parameters provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The basic Phase 1 parameters identify the remote peer or clients and support authentication through preshared keys or digital certificates. You can increase VPN connection security further using methods such as extended authentication (XAuth).

Phase 2 parameters provides detailed step-by-step procedures for configuring an IPsec VPN tunnel. During Phase 2, the specific IPsec security associations needed to implement security services are selected and a tunnel is established.

Defining VPN security policies explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN tunnel, and how to define a security encryption policy. Security policies control all IP traffic passing between a source address and a destination address.

Logging and monitoring and Troubleshooting provide VPN monitoring and troubleshooting procedures.

IPsec VPN concepts

Virtual Private Network (VPN) technology enables remote users to connect to private computer networks to gain access to their resources in a secure way. For example, an employee traveling or working from home can use a VPN to securely access the office network through the Internet.

Instead of remotely logging on to a private network using an unencrypted and unsecure Internet connection, the use of a VPN ensures that unauthorized parties cannot access the office network and cannot intercept any of the information that is exchanged between the employee and the office. It is also common to use a VPN to connect the private networks of two or more offices.

Fortinet offers VPN capabilities in the FortiGate Unified Threat Management (UTM) appliance and in the FortiClient Endpoint Security suite of applications. A FortiGate unit can be installed on a private network, and FortiClient software can be installed on the user's computer. It is also possible to use a FortiGate unit to connect to the private network instead of using FortiClient software.

This chapter discusses VPN terms and concepts including:

VPN tunnels
VPN gateways
Clients, servers, and peers
Encryption
Authentication
Phase 1 and Phase 2 settings
Security Association
IKE and IPsec packet processing

VPN tunnels

The data path between a user's computer and a private network through a VPN is referred to as a tunnel. Like a physical tunnel, the data path is accessible only at both ends. In the telecommuting scenario, the tunnel runs between the FortiClient application on the user's PC, or a FortiGate unit or other network device and the FortiGate unit on the office private network.

Encapsulation makes this possible. IPsec packets pass from one end of the tunnel to the other and contain data packets that are exchanged between the local user and the remote private network. Encryption of the data packets ensures that any third-party who intercepts the IPsec packets can not access the data.

Encoded data going through a VPN tunnel

You can create a VPN tunnel between:

- A PC equipped with the FortiClient application and a FortiGate unit
- Two FortiGate units
- Third-party VPN software and a FortiGate unit
  For more information on third-party VPN software, refer to the Fortinet Knowledge Base for more information.

Tunnel templates

Several tunnel templates are available in the IPsec VPN Wizard that cover a variety of different types of IPsec VPN. A list of these templates appear on the first page of the Wizard, located at **VPN > IPsec > Wizard**. The tunnel template list follows.

IPsec VPN Wizard tunnel templates

Template type	Description
Dialup - FortiClient (Windows, MacOS, Android)	On-demand tunnel for users using the FortiClient software.
Site to Site - FortiGate	Static tunnel between this FortiGate and a remote FortiGate.
Dialup - iOS (Native)	On-demand tunnel for iPhone/iPad users using the native iOS IPsec client.
Dialup - Android (Native L2TP/IPsec)	On-demand tunnel for Android users using the native L2TP/IPsec client.
Dialup - Cisco Firewall	On-demand tunnel for users using the Cisco IPsec client.
Site to Site - Cisco	Static tunnel between this FortiGate and a remote Cisco firewall.
Custom VPN Tunnel	No Template.

VPN tunnel list

Once you create an IPsec VPN tunnel, it appears in the VPN tunnel list at **VPN > IPsec > Tunnels**. By default, the tunnel list indicates the name of the tunnel, its interface binding, the tunnel template used, and the tunnel status. If you right-click on the table header row, you can include columns for comments, IKE version, mode (aggressive vs main), phase 2 proposals, and reference number. The tunnel list page also includes the option to create a new tunnel, as well as the options to edit or delete a highlighted tunnel.

VPN gateways

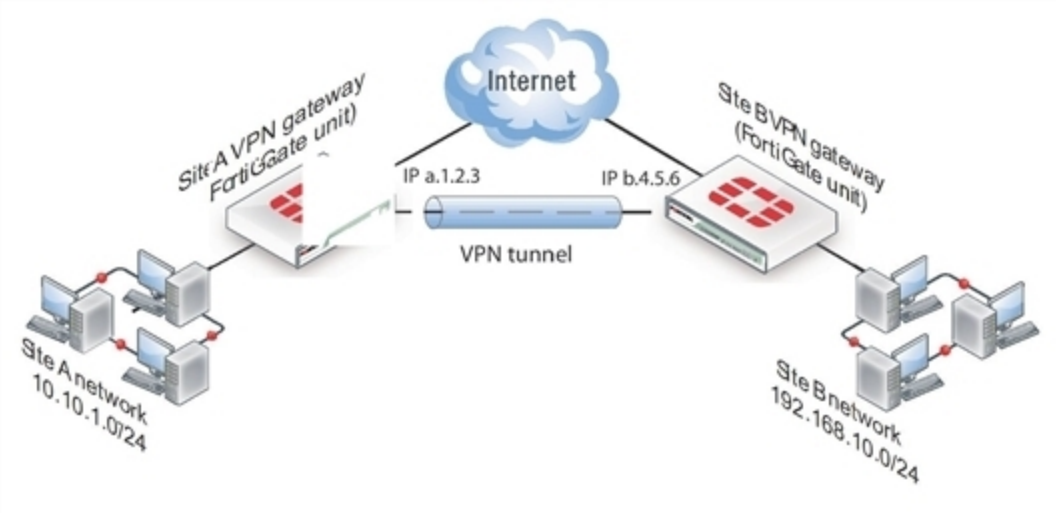
A gateway is a router that connects the local network to other networks. The default gateway setting in your computer's TCP/IP properties specifies the gateway for your local network.

A VPN gateway functions as one end of a VPN tunnel. It receives incoming IPsec packets, decrypts the encapsulated data packets and passes the data packets to the local network. Also, it encrypts data packets destined for the other end of the VPN tunnel, encapsulates them, and sends the IPsec packets to the other VPN gateway. The VPN gateway is a FortiGate unit because the private network behind it is protected, ensuring the security of the unencrypted VPN data. The gateway can also be FortiClient software running on a PC since the unencrypted data is secure on the PC.

The IP address of a VPN gateway is usually the IP address of the network interface that connects to the Internet. Optionally, you can define a secondary IP address for the interface and use that address as the local VPN gateway address. The benefit of doing this is that your existing setup is not affected by the VPN settings.

The following diagram shows a VPN connection between two private networks with FortiGate units acting as the VPN gateways. This configuration is commonly referred to as Gateway-to-Gateway IPsec VPN.

VPN tunnel between two private networks



Although the IPsec traffic may actually pass through many Internet routers, you can visualize the VPN tunnel as a simple secure connection between the two FortiGate units.

Users on the two private networks do not need to be aware of the VPN tunnel. The applications on their computers generate packets with the appropriate source and destination addresses, as they normally do. The FortiGate units manage all the details of encrypting, encapsulating, and sending the packets to the remote VPN gateway.

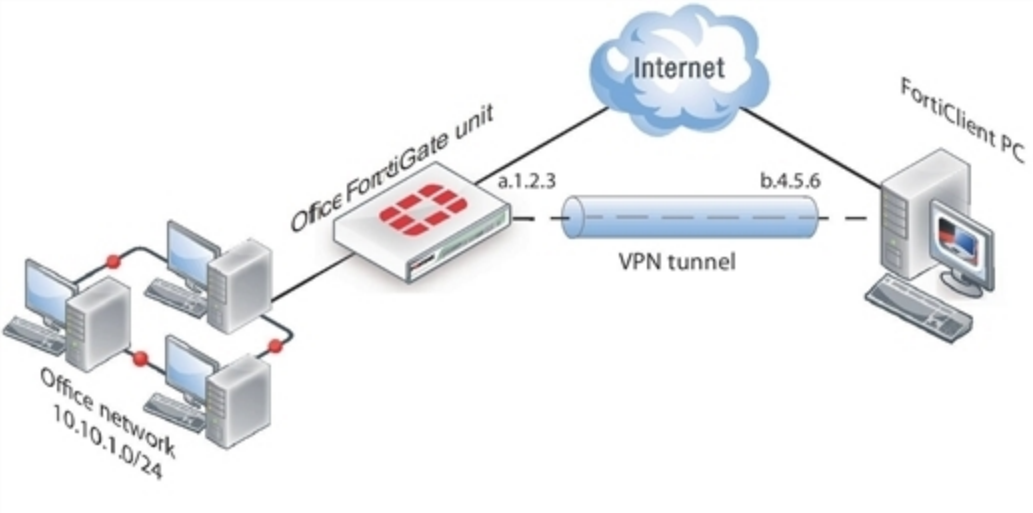
The data is encapsulated in IPsec packets only in the VPN tunnel between the two VPN gateways. Between the user's computer and the gateway, the data is on the secure private network and it is in regular IP packets.

For example User1 on the Site A network, at IP address 10.10.1.7, sends packets with destination IP address 192.168.10.8, the address of User2 on the Site B network. The Site A FortiGate unit is configured to send packets with destinations on the 192.168.10.0 network through the VPN, encrypted and encapsulated. Similarly, the Site B FortiGate unit is configured to send packets with destinations on the 10.10.1.0 network through the VPN tunnel to the Site A VPN gateway.

In the site-to-site, or gateway-to-gateway VPN shown below, the FortiGate units have static (fixed) IP addresses and either unit can initiate communication.

You can also create a VPN tunnel between an individual PC running FortiClient and a FortiGate unit, as shown below. This is commonly referred to as Client-to-Gateway IPsec VPN.

VPN tunnel between a FortiClient PC and a FortiGate unit



On the PC, the FortiClient application acts as the local VPN gateway. Packets destined for the office network are encrypted, encapsulated into IPsec packets, and sent through the VPN tunnel to the FortiGate unit. Packets for other destinations are routed to the Internet as usual. IPsec packets arriving through the tunnel are decrypted to recover the original IP packets.

Clients, servers, and peers

A FortiGate unit in a VPN can have one of the following roles:

- **Server** — responds to a request to establish a VPN tunnel.
- **Client** — contacts a remote VPN gateway and requests a VPN tunnel.
- **Peer** — brings up a VPN tunnel or responds to a request to do so.

The site-to-site VPN shown above is a peer-to-peer relationship. Either FortiGate unit VPN gateway can establish the tunnel and initiate communications. The FortiClient-to-FortiGate VPN shown below is a client-server relationship. The FortiGate unit establishes a tunnel when the FortiClient PC requests one.

A FortiGate unit cannot be a VPN server if it has a dynamically-assigned IP address. VPN clients need to be configured with a static IP address for the server. A FortiGate unit acts as a server only when the remote VPN gateway has a dynamic IP address or is a client-only device or application, such as FortiClient.

As a VPN server, a FortiGate unit can also offer automatic configuration for FortiClient PCs. The user needs to know only the IP address of the FortiGate VPN server and a valid user name/password. FortiClient downloads the VPN configuration settings from the FortiGate VPN server. For information about configuring a FortiGate unit as a VPN server, see the FortiClient Administration Guide.

Encryption

Encryption mathematically transforms data to appear as meaningless random numbers. The original data is called plaintext and the encrypted data is called ciphertext. The opposite process, called decryption, performs the inverse operation to recover the original plaintext from the ciphertext.

The process by which the plaintext is transformed to ciphertext and back again is called an algorithm. All algorithms use a small piece of information, a key, in the arithmetic process of converted plaintext to ciphertext,

or vice-versa. IPsec uses symmetrical algorithms, in which the same key is used to both encrypt and decrypt the data. The security of an encryption algorithm is determined by the length of the key that it uses. FortiGate IPsec VPNs offer the following encryption algorithms, in descending order of security:

AES256	A 128-bit block algorithm that uses a 256-bit key.
AES192	A 128-bit block algorithm that uses a 192-bit key.
AES128	A 128-bit block algorithm that uses a 128-bit key.
3DES	Triple-DES, in which plain text is DES-encrypted three times by three keys.
DES	Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key

The default encryption algorithms provided on FortiGate units make recovery of encrypted data almost impossible without the proper encryption keys.

There is a human factor in the security of encryption. The key must be kept secret, known only to the sender and receiver of the messages. Also, the key must not be something that unauthorized parties might easily guess, such as the sender's name, birthday or simple sequence such as `123456`.

IPsec overheads

The FortiGate sets an IPsec tunnel Maximum Transmission Unit (MTU) of 1436 for 3DES/SHA1 and an MTU of 1412 for AES128/SHA1, as seen with `diag vpn tunnel list`. This indicates that the FortiGate allocates 64 bytes of overhead for 3DES/SHA1 and 88 bytes for AES128/SHA1, which is the difference if you subtract this MTU from a typical ethernet MTU of 1500 bytes.

During the encryption process, AES/DES operates using a specific size of data which is block size. If data is smaller than that, it will be padded for the operation. MD5/SHA-1 HMAC also operates using a specific block size.

The following table describes the potential maximum overhead for each IPsec encryption:

IPsec Transform Set	IPsec Overhead (Max. bytes)
ESP-AES (256, 192, or 128),ESP-SHA-HMAC, or MD5	73
ESP-AES (256, 192, or 128)	61
ESP-3DES, ESP-DES	45
ESP-(DES or 3DES), ESP-SHA-HMAC, or MD5	57
ESP-Null, ESP-SHA-HMAC, or MD5	45
AH-SHA-HMAC or MD5	44

Authentication

To protect data via encryption, a VPN must ensure that only authorized users can access the private network. You must use either a preshared key on both VPN gateways or RSA X.509 security certificates. The examples in this

guide use only preshared key authentication. Refer to the Fortinet Knowledge Base for articles on RSA X.509 security certificates.

Preshared keys

A preshared key contains at least six random alphanumeric characters. Users of the VPN must obtain the preshared key from the person who manages the VPN server and add the preshared key to their VPN client configuration.

Although it looks like a password, the preshared key, also known as a shared secret, is never sent by either gateway. The preshared key is used in the calculations at each end that generate the encryption keys. As soon as the VPN peers attempt to exchange encrypted data, preshared keys that do not match will cause the process to fail.

Additional authentication

To increase security, you can require additional means of authentication from users, such as:

- An identifier, called a peer ID or a local ID.
- Extended authentication (XAUTH) which imposes an additional user name/password requirement.

A Local ID is an alphanumeric value assigned in the Phase 1 configuration. The Local ID of a peer is called a Peer ID.

In FortiOS 5.2, new authentication methods have been implemented for IKE: ECDSA-256, ECDSA-384, and ECDSA-521. However, AES-XCBC is not supported.

Phase 1 and Phase 2 settings

A VPN tunnel is established in two phases: Phase 1 and Phase 2. Several parameters determine how this is done. Except for IP addresses, the settings simply need to match at both VPN gateways. There are defaults that are appropriate for most cases.

FortiClient distinguishes between Phase 1 and Phase 2 only in the VPN Advanced settings and uses different terms. Phase 1 is called the IKE Policy. Phase 2 is called the IPsec Policy.

Phase 1

In Phase 1, the two VPN gateways exchange information about the encryption algorithms that they support and then establish a temporary secure connection to exchange authentication information.

When you configure your FortiGate unit or FortiClient application, you must specify the following settings for Phase 1:

Remote gateway	The remote VPN gateway's address. FortiGate units also have the option of operating only as a server by selecting the "Dialup User" option.
Preshared key	This must be the same at both ends. It is used to encrypt Phase 1 authentication information.
Local interface	The network interface that connects to the other VPN gateway. This applies on a FortiGate unit only.

All other Phase 1 settings have default values. These settings mainly configure the types of encryption to be used. The default settings on FortiGate units and in the FortiClient application are compatible. The examples in this guide use these defaults.

For more detailed information about Phase 1 settings, see Phase 1 parameters on page 1581.

Phase 2

Similar to the Phase 1 process, the two VPN gateways exchange information about the encryption algorithms that they support for Phase 2. You may choose different encryption for Phase 1 and Phase 2. If both gateways have at least one encryption algorithm in common, a VPN tunnel can be established. Keep in mind that more algorithms each phase does not share with the other gateway, the longer negotiations will take. In extreme cases this may cause timeouts during negotiations.

To configure default Phase 2 settings on a FortiGate unit, you need only select the name of the corresponding Phase 1 configuration. In FortiClient, no action is required to enable default Phase 2 settings.

For more detailed information about Phase 2 settings, see Phase 2 parameters on page 1598.

Security Association

The establishment of a Security Association (SA) is the successful outcome of Phase 1 negotiations. Each peer maintains a database of information about VPN connections. The information in each SA can include cryptographic algorithms and keys, keylife, and the current packet sequence number. This information is kept synchronized as the VPN operates. Each SA has a Security Parameter Index (SPI) that is provided to the remote peer at the time the SA is established. Subsequent IPsec packets from the peer always reference the relevant SPI. It is possible for peers to have multiple VPNs active simultaneously, and correspondingly multiple SPIs.

IKE and IPsec packet processing

Internet Key Exchange (IKE) is the protocol used to set up SAs in IPsec negotiation. As described in Phase 1 parameters on page 1581, you can optionally choose IKEv2 over IKEv1 if you configure a route-based IPsec VPN. IKEv2 simplifies the negotiation process, in that it:

- Provides no choice of Aggressive or Main mode in Phase 1.
- Does not support Peer Options or Local ID.
- Does not allow Extended Authentication (XAUTH).
- Allows you to select only one Diffie-Hellman Group.
- Uses less bandwidth.

The following sections identify how IKE versions 1 and 2 operate and differentiate.

IKEv1

Phase 1

A peer, identifed in the IPsec policy configuration, begins the IKE negotiation process. This IKE Security Association (SA) agreement is known as Phase 1. The Phase 1 parameters identify the remote peer or clients and supports authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes. Basically, Phase 1 authenticates a remote peer and sets up a secure communication channel for establishing Phase 2, which negotiates the IPsec SA.

IKE Phase 1 can occur in either Main mode or Aggressive mode. For more information, see Phase 1 parameters on page 1581.

IKE Phase 1 is successful only when the following are true:

- Each peer negotiates a matching IKE SA policy.
- Each peer is authenticated and their identities protected.
- The Diffie-Hellman exchange is authenticated (the pre-shared secret keys match).

For more information on Phase 1, see Phase 1 parameters on page 1581.

Phase 2

Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session in an IPsec SA. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a more secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of the SA. The keys are generated automatically using a Diffie-Hellman algorithm.

In Phase 2, Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure. For more information, see Phase 2 parameters on page 1598.

IKE Phase 2 is successful only when the following are true:

- The IPsec SA is established and protected by the IKE SA.
- The IPsec SA is configured to renegotiate after set durations (see Phase 2 parameters on page 1598 and Phase 2 parameters on page 1598).
- **Optional:** Replay Detection is enabled. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel. See Phase 2 parameters on page 1598.
- **Optional:** Perfect Forward Secrecy (PFS) is enabled. PFS improves security by forcing a new Diffie-Hellman exchange whenever keylife expires. See Phase 2 parameters on page 1598.

For more information on Phase 2, see Phase 2 parameters on page 1598.

With Phase 2 established, the IPsec tunnel is fully negotiated and traffic between the peers is allowed until the SA terminates (for any number of reasons; time-out, interruption, disconnection, etc).

IKEv2

Phase 1

Unlike Phase 1 of IKEv1, IKEv2 does not provide options for Aggressive or Main mode. Furthermore, Phase 1 of IKEv2 begins immediately with an IKE SA initiation, consisting of only two packets (containing all the information typically contained in four packets for IKEv1), securing the channel such that all following transactions are encrypted (see Phase 1 parameters on page 1581).

The encrypted transactions contain the IKE authentication, since remote peers have yet to be authenticated. This stage of IKE authentication in IKEv2 can loosely be called Phase 1.5.

Phase 1.5

As part of this phase, IKE authentication must occur. IKE authentication consists of the following:

- The authentication payloads and Internet Security Association and Key Management Protocol (ISAKMP) identifier.
- The authentication method (RSA, PSK, ECDSA, or EAP).
- The IPsec SA parameters.

Due to the number of authentication methods potentially used, and SAs established, the overall IKEv2 negotiation can range from 4 packets (no EAP exchange at all) to many more.

At this point, both peers have a security association complete and ready to encrypt traffic.

Phase 2

In IKEv1, Phase 2 uses Quick mode to negotiate an IPsec SA between peers. In IKEv2, since the IPsec SA is already established, Phase 2 is essentially only used to negotiate “child” SAs, or to re-key an IPsec SA. That said, there are only two packets for each exchange of this type, similar to the exchange at the outset of Phase 1.5.

IPsec VPN overview

This section provides a brief overview of IPsec technology and includes general information about how to configure IPsec VPNs using this guide.

The following topics are included in this section:

Types of VPNs
Planning your VPN
General preparation steps
How to use this guide to configure an IPsec VPN

VPN configurations interact with the firewall component of the FortiGate unit. There must be a security policy in place to permit traffic to pass between the private network and the VPN tunnel.

Security policies for VPNs specify:

- The FortiGate interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- The FortiGate interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- Optionally, a schedule that restricts when the VPN can operate
- Optionally, the services (types of data) that can be sent

When the first packet of data that meets all of the conditions of the security policy arrives at the FortiGate unit, a VPN tunnel may be initiated and the encryption or decryption of data is performed automatically afterward. For more information, see Defining VPN security policies on page 1603.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Types of VPNs

FortiGate unit VPNs can be policy-based or route-based. There is little difference between the two types. In both cases, you specify Phase 1 and Phase 2 settings. However there is a difference in implementation. A route-based VPN creates a virtual IPsec network interface that applies encryption or decryption as needed to any traffic that it carries. That is why route-based VPNs are also known as interface-based VPNs. A policy-based VPN is implemented through a special security policy that applies the encryption you specified in the Phase 1 and Phase 2 settings.

Route-based VPNs

For a route-based VPN, you create two security policies between the virtual IPsec interface and the interface that connects to the private network. In one policy, the virtual interface is the source. In the other policy, the virtual interface is the destination. This creates bidirectional policies that ensure traffic will flow in both directions over the VPN.

A route-based VPN is also known as an interface-based VPN.

Each route-based IPsec VPN tunnel requires a virtual IPsec interface. As such, the amount of possible route-based IPsec VPNs is limited by the **system.interface** table size. The **system.interface** table size for most devices is 8192.

For a complete list of table sizes for all devices, refer to the Maximum Values table.

Policy-based VPNs

For a policy-based VPN, one security policy enables communication in both directions. You enable inbound and outbound traffic as needed within that policy, or create multiple policies of this type to handle different types of traffic differently. For example HTTPS traffic may not require the same level of scanning as FTP traffic.

A policy-based VPN is also known as a tunnel-mode VPN.

Comparing policy-based or route-based VPNs

For both VPN types you create Phase 1 and Phase 2 configurations. Both types are handled in the stateful inspection security layer, assuming there is no IPS or AV. For more information on the three security layers, see the FortiOS Troubleshooting guide.

The main difference is in the security policy.

You create a policy-based VPN by defining an IPSEC security policy between two network interfaces and associating it with the VPN tunnel (Phase 1) configuration.

You create a route-based VPN by creating a virtual IPsec interface. You then define a regular ACCEPT security policy to permit traffic to flow between the virtual IPsec interface and another network interface. And lastly, configure a static route to allow traffic over the VPN.

Where possible, you should create route-based VPNs. Generally, route-based VPNs are more flexible and easier to configure than policy-based VPNs — by default they are treated as interfaces. However, these two VPN types have different requirements that limit where they can be used.

Comparison of policy-based and route-based VPNs

Features	Policy-based	Route-based
Both NAT and transparent modes available	Yes	NAT mode only
L2TP-over-IPsec supported	Yes	No
GRE-over-IPsec supported	No	Yes
security policy requirements	Requires a security policy with IPSEC action that specifies the VPN tunnel	Requires only a simple security policy with ACCEPT action
Number of policies per VPN	One policy controls connections in both directions	A separate policy is required for connections in each direction

Planning your VPN

It is a good idea to plan the VPN configuration ahead of time. This will save time later and help you configure your VPN correctly.

All VPN configurations are comprised of numerous required and optional parameters. Before you begin, you need to determine:

- Where the IP traffic originates and where it needs to be delivered
- Which hosts, servers, or networks to include in the VPN
- Which VPN devices to include in the configuration
- Through which interfaces the VPN devices communicate
- Through which interfaces do private networks access the VPN gateways

Once you have this information, you can select a VPN topology that suits the network environment.

Network topologies

The topology of your network will determine how remote peers and clients connect to the VPN and how VPN traffic is routed.

VPN network topologies and brief descriptions

Topology	Description
Gateway-to-gateway configurations	Standard one-to-one VPN between two FortiGate units. See Gateway-to-gateway configurations on page 1609.
Hub-and-spoke configurations	One central FortiGate unit has multiple VPNs to other remote FortiGate units. See Hub-and-spoke configurations on page 1623.
Dynamic DNS configuration	One end of the VPN tunnel has a changing IP address and the other end must go to a dynamic DNS server for the current IP address before establishing a tunnel. See Dynamic DNS configuration on page 1639.
FortiClient dialup-client configurations	Typically remote FortiClient dialup-clients use dynamic IP addresses through NAT devices. The FortiGate unit acts as a dialup server allowing dialup VPN connections from multiple sources. See FortiClient dialup-client configurations on page 1654.
FortiGate dialup-client configurations	Similar to FortiClient dialup-client configurations but with more gateway-to-gateway settings such as unique user authentication for multiple users on a single VPN tunnel. See FortiGate dialup-client configurations on page 1669.
Internet-browsing configuration	Secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. See Internet-browsing configuration on page 1682.
Redundant VPN configurations	Options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches. See Redundant VPN configurations on page 1686.
Transparent mode VPNs	In transparent mode, the FortiGate acts as a bridge with all incoming traffic being broadcast back out on all other interfaces. Routing and NAT must be performed on external routers. See Transparent mode VPNs on page 1711.
L2TP and IPsec (Microsoft VPN)	Configure VPN for Microsoft Windows dialup clients using the built in L2TP software. Users do not have to install any See L2TP and IPsec (Microsoft VPN) on page 1730.

These sections contain high-level configuration guidelines with cross-references to detailed configuration procedures. If you need more detail to complete a step, select the cross-reference in the step to drill-down to more detail. Return to the original procedure to complete the procedure. For a general overview of how to configure a VPN, see Planning your VPN .

General preparation steps

A VPN configuration defines relationships between the VPN devices and the private hosts, servers, or networks making up the VPN. Configuring a VPN involves gathering and recording the following information. You will need this information to configure the VPN.

- **The private IP addresses of participating hosts, servers, and/or networks.** These IP addresses represent the source addresses of traffic that is permitted to pass through the VPN. A IP source address can be an individual IP address, an address range, or a subnet address.
- **The public IP addresses of the VPN end-point interfaces.** The VPN devices establish tunnels with each other through these interfaces.
- **The private IP addresses associated with the VPN-device interfaces to the private networks.** Computers on the private networks behind the VPN gateways will connect to their VPN gateways through these interfaces.

How to use this guide to configure an IPsec VPN

This guide uses a task-based approach to provide all of the procedures needed to create different types of VPN configurations. Follow the step-by-step configuration procedures in this guide to set up the VPN.

The following configuration procedures are common to all IPsec VPNs:

1. Define the Phase 1 parameters that the FortiGate unit needs to authenticate remote peers or clients and establish a secure a connection. See Phase 1 parameters on page 1581.
2. Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with a remote peer or dialup client. See Phase 2 parameters on page 1598.
3. Specify the source and destination addresses of IP packets that are to be transported through the VPN tunnel. See Defining VPN security policies on page 1603.
4. Create an IPsec security policy to define the scope of permitted services between the IP source and destination addresses. See Defining VPN security policies on page 1603.

These steps assume you configure the FortiGate unit to generate unique IPsec encryption and authentication keys automatically. In situations where a remote VPN peer or client requires a specific IPsec encryption and authentication key, you must configure the FortiGate unit to use manual keys instead of performing Steps 1 and 2.

IPsec VPN in the web-based manager

To configure an IPsec VPN, use the general procedure below. With these steps, your FortiGate unit will automatically generate unique IPsec encryption and authentication keys. If a remote VPN peer or client requires a specific IPsec encryption or authentication key, you must configure your FortiGate unit to use manual keys instead.

1. Define Phase 1 parameters to authenticate remote peers and clients for a secure connection. See IPsec VPN in the web-based manager on page 1568.
2. Define Phase 2 parameters to create a VPN tunnel with a remote peer or dialup client. See IPsec VPN in the web-based manager on page 1568.
3. Create a security policy to permit communication between your private network and the VPN. Policy-based VPNs have an action of IPSEC, where for interface-based VPNs the security policy action is ACCEPT. See Defining VPN security policies on page 1603.

The FortiGate unit implements the Encapsulated Security Payload (ESP) protocol. Internet Key Exchange (IKE) is performed automatically based on pre-shared keys or X.509 digital certificates. Interface mode, supported in NAT mode only, creates a virtual interface for the local end of a VPN tunnel.

This chapter contains the following sections:

Phase 1 configuration
Phase 2 configuration
Concentrator
IPsec Monitor

Phase 1 configuration

To begin defining the Phase 1 configuration, go to **VPN > IPsec > Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

If you want to control how the IKE negotiation is processed when there is no traffic, as well as the length of time the FortiGate unit waits for negotiations to occur, you can use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

For more information, refer to Phase 2 parameters on page 1598 and Phase 2 parameters on page 1598.

Name	Type a name for the Phase 1 definition. The maximum name length is 15 characters for an interface mode VPN, 35 characters for a policy-based VPN. If **Remote Gateway** is **Dialup User**, the maximum name length is further reduced depending on the number of dialup tunnels that can be established: by 2 for up to 9 tunnels, by 3 for up to 99 tunnels, 4 for up to 999 tunnels, and so on. For a tunnel mode VPN, the name normally reflects where the remote connection originates. For a route-based tunnel, the FortiGate unit also uses the name for the virtual IPsec interface that it creates automatically.
Remote Gateway	Select the category of the remote connection: **Static IP Address** — If the remote peer has a static IP address. **Dialup User** — If one or more FortiClient or FortiGate dialup clients with dynamic IP addresses will connect to the FortiGate unit. **Dynamic DNS** — If a remote peer that has a domain name and subscribes to a dynamic DNS service will connect to the FortiGate unit.
IP Address	If you selected **Static IP Address**, enter the IP address of the remote peer.
Dynamic DNS	If you selected ***Dynamic DNS***, enter the domain name of the remote peer.
Local Interface	This option is available in NAT mode only. Select the name of the interface through which remote peers or dialup clients connect to the FortiGate unit. By default, the local VPN gateway IP address is the IP address of the interface that you selected.
Mode	**Main mode** — the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information. **Aggressive mode** — the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted. When the remote VPN peer has a dynamic IP address and is authenticated by a pre-shared key, you must select Aggressive mode if there is more than one dialup phase1 configuration for the interface IP address. When the remote VPN peer has a dynamic IP address and is authenticated by a certificate, you must select Aggressive mode if there is more than one Phase 1 configuration for the interface IP address and these Phase 1 configurations use different proposals.
Authentication Method	Select **Preshared Key** or **RSA Signature**.

Pre-shared Key	If you selected **Pre-shared Key**, enter the pre-shared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same key at the remote peer or client. The key must contain at least 6 printable characters. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
Certificate Name	If you selected **RSA Signature**, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. For information about obtaining and loading the required server certificate, see the FortiOS User Authentication guide.
Peer Options	Peer options are available to authenticate VPN peers or clients, depending on the **Remote Gateway** and **Authentication Method** settings.
Any peer ID	Accept the local ID of any remote VPN peer or client. The FortiGate unit does not check identifiers (local IDs). You can set **Mode** to **Aggressive** or **Main**. You can use this option with RSA Signature authentication. But, for highest security, configure a PKI user/group for the peer and set **Peer Options** to **Accept this peer certificate only**.
This peer ID	This option is available when **Aggressive Mode** is enabled. Enter the identifier that is used to authenticate the remote peer. This identifier must match the Local ID that the remote peer's administrator has configured. If the remote peer is a FortiGate unit, the identifier is specified in the **Local ID** field of the Advanced Phase 1 configuration. If the remote peer is a FortiClient user, the identifier is specified in the **Local ID** field, accessed by selecting **Config** in the **Policy** section of the VPN connection's **Advanced Settings**.
Peer ID from dialup group	Authenticate multiple FortiGate or FortiClient dialup clients that use unique identifiers and unique pre-shared keys (or unique pre-shared keys only) through the same VPN tunnel. You must create a dialup user group for authentication purposes. Select the group from the list next to the **Peer ID from dialup group** option. You must set **Mode** to **Aggressive** when the dialup clients use unique identifiers and unique pre-shared keys. If the dialup clients use unique pre-shared keys only, you can set **Mode** to **Main** if there is only one dialup Phase 1 configuration for this interface IP address.

Phase 1 advanced configuration settings

You can use the following advanced parameters to select the encryption and authentication algorithms that the FortiGate unit uses to generate keys for the IKE exchange. You can also use the following advanced parameters

to ensure the smooth operation of Phase 1 negotiations.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

IPv6 Version	Select if you want to use IPv6 addresses for the remote gateway and interface IP addresses.
Local Gateway IP	Specify an IP address for the local end of the VPN tunnel. Select one of the following: **Main Interface IP** — The FortiGate unit obtains the IP address of the interface from the network interface settings. **Specify** — Enter a secondary address of the interface selected in the Phase 1 **Local Interface** field. You cannot configure Interface mode in a transparent mode VDOM.
Phase 1 Proposal	Select the encryption and authentication algorithms used to generate keys for protecting negotiations and add encryption and authentication algorithms as required. You need to select a minimum of one and a maximum of three combinations. The remote peer or client must be configured to use at least one of the proposals that you define. Select one of the following symmetric-key encryption algorithms: **DES** — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. **3DES** — Triple-DES; plain text is encrypted three times by three keys. **AES128** — A 128-bit block algorithm that uses a 128-bit key. **AES192** — A 128-bit block algorithm that uses a 192-bit key. **AES256** — A 128-bit block algorithm that uses a 256-bit key.
	You can select either of the following message digests to check the authenticity of messages during an encrypted session: **MD5** — Message Digest 5. **SHA1** — Secure Hash Algorithm 1 - a 160-bit message digest. To specify one combination only, set the **Encryption** and **Authentication** options of the second combination to NULL. To specify a third combination, use the **Add** button beside the fields for the second combination.
Diffie-Hellman Group	Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, and 14 through 21. At least one of the **Diffie-Hellman Group** settings on the remote peer or client must match one the selections on the FortiGate unit. Failure to match one or more DH groups will result in failed negotiations.
Keylife	Enter the time (in seconds) that must pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172 800 seconds.

Local ID	If the FortiGate unit will act as a VPN client and you are using peer IDs for authentication purposes, enter the identifier that the FortiGate unit will supply to the VPN server during the Phase 1 exchange. If the FortiGate unit will act as a VPN client, and you are using security certificates for authentication, select the distinguished name (DN) of the local server certificate that the FortiGate unit will use for authentication purposes. If the FortiGate unit is a dialup client and will not be sharing a tunnel with other dialup clients (that is, the tunnel will be dedicated to this Fortinet dialup client), set **Mode** to **Aggressive**. Note that this Local ID value must match the peer ID value given for the remote VPN peer's Peer Options.
XAuth	This option supports the authentication of dialup clients. It is available for IKE v1 only. **Disable** — Select if you do not use XAuth. **Enable as Client** — If the FortiGate unit is a dialup client, enter the user name and password that the FortiGate unit will need to authenticate itself to the remote XAuth server. **Enable as Server** — This is available only if **Remote Gateway** is set to **Dialup User**. Dialup clients authenticate as members of a dialup user group. You must first create a user group for the dialup clients that need access to the network behind the FortiGate unit. You must also configure the FortiGate unit to forward authentication requests to an external RADIUS or LDAP authentication server. Select a **Server Type** setting to determine the type of encryption method to use between the FortiGate unit, the XAuth client and the external authentication server, and then select the user group from the User Group list.
Username	Enter the user name that is used for authentication.
Password	Enter the password that is used for authentication.
NAT Traversal	Select the check box if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared) to connect reliably.
Keepalive Frequency	If you enabled **NAT-traversal**, enter a keepalive frequency setting.

Dead Peer Detection	Select this check box to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. You can use this option to receive notification whenever a tunnel goes up or down, or to keep the tunnel connection open when no traffic is being generated inside the tunnel. For example, in scenarios where a dialup client or dynamic DNS peer connects from an IP address that changes periodically, traffic may be suspended while the IP address changes. With **Dead Peer Detection** selected, you can use the `config vpn ipsec phase1` (tunnel mode) or `config vpn ipsec phase1-interface` (interface mode) CLI command to optionally specify a retry count and a retry interval.

IKE fragmentation

UDP fragmentation can cause issues in IPsec when either the ISP or perimeter firewall(s) cannot pass or fragment the oversized UDP packets that occur when using a very large public security key (PSK). The result is that IPsec tunnels do not come up. The solution is IKE fragmentation.

For most configurations, enabling IKE fragmentation allows connections to automatically establish when they otherwise might have failed due to intermediate nodes dropping IKE messages containing large certificates, which typically push the packet size over 1500 bytes.

FortiOS will fragment a packet on sending if, and only if, all the following are true:

- Phase 1 contains "`set fragmentation enable`".
- The packet is larger than the minimum MTU (576 for IPv4, 1280 for IPv6).
- The packet is being re-transmitted.

By default, IKE fragmentation is enabled, but upon upgrading, any existing phase1-interface may have have "`set fragmentation disable`" added in order to preserve the existing behaviour of not supporting fragmentation.

To enable or disable IKE fragmentation - CLI

```
config vpn ipsec phase1-interface
   edit 1
      set fragmentation [enable | disable]
   next
end
```

Phase 2 configuration

After IPsec Phase 1 negotiations end successfully, you begin Phase 2. You can configure the Phase 2 parameters to define the algorithms that the FortiGate unit may use to encrypt and transfer data for the remainder of the session. During Phase 2, you select specific IPsec security associations needed to implement security services and establish a tunnel.

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration that specifies the remote end point of the VPN tunnel. In most cases, you need to configure only basic Phase 2 settings.

These settings are mainly configured in the CLI, although some options are available after the tunnel is created using the VPN Creation Wizard (using the **Convert to Custom Tunnel** option).

Name	Type a name to identify the Phase 2 configuration.
Phase 1	Select the Phase 1 tunnel configuration. For more information on configuring Phase 1, see Phase 1 configuration on page 1568. The Phase 1 configuration describes how remote VPN peers or clients will be authenticated on this tunnel, and how the connection to the remote peer or client will be secured.
Advanced	Define advanced Phase 2 parameters. For more information, see Phase 2 advanced configuration settings below.

Phase 2 advanced configuration settings

In Phase 2, the FortiGate unit and the VPN peer or client exchange keys again to establish a secure communication channel between them. You select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). These are called Phase 2 Proposal parameters. The keys are generated automatically using a Diffie-Hellman algorithm.

You can use a number of additional advanced Phase 2 settings to enhance the operation of the tunnel.

Phase 2 Proposal	Select the encryption and authentication algorithms that will be proposed to the remote VPN peer. You can specify up to three proposals. To establish a VPN connection, at least one of the proposals that you specify must match configuration on the remote peer. Initially there are two proposals. **Add** and **Delete** icons are next to the second **Authentication** field. It is invalid to set both **Encryption** and **Authentication** to **NULL**.
Encryption	Select a symmetric-key algorithms: **NULL** — Do not use an encryption algorithm. **DES** — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. **3DES** — Triple-DES; plain text is encrypted three times by three keys. **AES128** — A 128-bit block algorithm that uses a 128-bit key. **AES192** — A 128-bit block algorithm that uses a 192-bit key. **AES256** — A 128-bit block algorithm that uses a 256-bit key.
Authentication	You can select either of the following message digests to check the authenticity of messages during an encrypted session: **NULL** — Do not use a message digest. **MD5** — Message Digest 5. **SHA1** — Secure Hash Algorithm 1 - a 160-bit message digest. To specify one combination only, set the **Encryption** and **Authentication** options of the second combination to NULL. To specify a third combination, use the ***Add*** button beside the fields for the second combination.
Enable replay detection	Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
Diffie-Hellman Group	Select one Diffie-Hellman group (1, 2, 5, or 14 through 21). This must match the DH Group that the remote peer or dialup client uses.
Keylife	Select the method for determining when the Phase 2 key expires: **Seconds**, **KBytes**, or **Both**. If you select **Both**, the key expires when either the time has passed or the number of KB have been processed.
Autokey Keep Alive	Select the check box if you want the tunnel to remain active when no data is being processed.
Auto-negotiate	Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.

DHCP-IPsec	Provide IP addresses dynamically to VPN clients. This is available for Phase 2 configurations associated with a dialup Phase 1 configuration. You also need configure a DHCP server or relay on the private network interface. You must configure the DHCP parameters separately. If you configure the DHCP server to assign IP addresses based on RADIUS user group attributes, you must also set the Phase 1 **Peer Options** to **Peer ID from dialup group** and select the appropriate user group. See Phase 1 configuration on page 1568. If the FortiGate unit acts as a dialup server and you manually assigned FortiClient dialup clients VIP addresses that match the network behind the dialup server, selecting the check box will cause the FortiGate unit to act as a proxy for the dialup clients.
Quick Mode Selector	Specify the source and destination IP addresses to be used as selectors for IKE negotiations. If the FortiGate unit is a dialup server, keep the default value of 0.0.0.0/0 unless you need to circumvent problems caused by ambiguous IP addresses between one or more of the private networks making up the VPN. You can specify a single host IP address, an IP address range, or a network address. You may optionally specify source and destination port numbers and a protocol number. If you are editing an existing Phase 2 configuration, the **Source address** and **Destination address** fields are unavailable if the tunnel has been configured to use firewall addresses as selectors. This option exists only in the CLI.
Source address	If the FortiGate unit is a dialup server, enter the source IP address that corresponds to the local senders or network behind the local VPN peer (for example, `172.16.5.0/24` or `172.16.5.0/255.255.255.0` for a subnet, or `172.16.5.1/32` or `172.16.5.1/255.255.255.255` for a server or host, or `192.168.10.[80-100]` or `192.168.10.80-192.168.10.100` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the local VPN peer. If the FortiGate unit is a dialup client, source address must refer to the private network behind the Fortinet dialup client.
Source port	Enter the port number that the local VPN peer uses to transport traffic related to the specified service (protocol number). The range is from 0 to 65535. To specify all ports, type `0`.
Destination address	Enter the destination IP address that corresponds to the recipients or network behind the remote VPN peer (for example, `192.168.20.0/24` for a subnet, or `172.16.5.1/32` for a server or host, or `192.168.10.[80-100]` for an address range). A value of `0.0.0.0/0` means all IP addresses behind the remote VPN peer.

Destination port	Enter the port number that the remote VPN peer uses to transport traffic related to the specified service (protocol number). To specify all ports, enter `0`.
Protocol	Enter the IP protocol number of the service. To specify all services, enter `0`.

FortiClient VPN

Use the **Dialup - FortiClient (Windows, MacOS, Android)** VPN Wizard option when configuring an IPsec VPN for remote users to connect to the VPN tunnel using FortiClient.

When configuring a FortiClient VPN connection, the settings for Phase 1 and Phase 2 settings are automatically configured by the FortiGate unit. They are set to:

- Remote Gateway — Dialup User
- Mode — Aggressive
- Default settings for Phase 1 and 2 Proposals
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option — “Any peer ID”

The remainder of the settings use the current FortiGate defaults. Note that FortiClient settings need to match these FortiGate defaults. If you need to configure advanced settings for the FortiClient VPN, you must do so using the CLI.

Name	Enter a name for the FortiClient VPN.
Local Outgoing Interface	Select the local outgoing interface for the VPN.
Authentication Method	Select the type of authentication used when logging in to the VPN.
Preshared Key	If **Pre-shared Key** was selected in **Authentication Method**, enter the pre-shared key in the field provided.
User Group	Select a user group. You can also create a user group from the drop-down list by selecting **Create New**.
Address Range Start IP	Enter the start IP address for the DHCP address range for the client.
Address Range End IP	Enter the end IP address for the address range.
Subnet Mask	Enter the subnet mask.
Enable IPv4 Split Tunnel	Enabled by default, this option enables the FortiClient user to use the VPN to access internal resources while other Internet access is not sent over the VPN, alleviating potential traffic bottlenecks in the VPN connection. Disable this option to have all traffic sent through the VPN tunnel.
Accessible Networks	Select from a list of internal networks that the FortiClient user can access.
Client Options	These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default. **Save Password** - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. **Auto Connect** - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. **Always Up (Keep Alive)** - When enabled, if the user selects this option, the FortiClient connection will not shut down. When not selected, during periods of inactivity, FortiClient will attempt to stay connected every three minutes for a maximum of 10 minutes.
Endpoint Registration	When selected, the FortiGate unit requests a registration key from FortiClient before a connection can be established. A registration key is defined by going to **System > Config > Advanced**. For more information on FortiClient VPN connections to a FortiGate unit, see the **FortiClient Administration Guide**.

DNS Server	Select which DNS server to use for this VPN: **Use System DNS** — Use the same DNS servers as the FortiGate unit. These are configured at **System > Interface > DNS**. This is the default option. **Specify** — Specify the IP address of a different DNS server.

Concentrator

In a hub-and-spoke configuration, policy-based VPN connections to a number of remote peers radiate from a single, central FortiGate unit. Site-to-site connections between the remote peers do not exist; however, you can establish VPN tunnels between any two of the remote peers through the FortiGate unit's "hub".

In a hub-and-spoke network, all VPN tunnels terminate at the hub. The peers that connect to the hub are known as "spokes". The hub functions as a concentrator on the network, managing all VPN connections between the spokes. VPN traffic passes from one tunnel to the other through the hub.

You define a concentrator to include spokes in the hub-and-spoke configuration. You create the concentrator in **VPN > IPsec > Concentrator** and select **Create New**. A concentrator configuration specifies which spokes to include in an IPsec hub-and-spoke configuration.

Concentrator Name	Type a name for the concentrator.
Available Tunnels	A list of defined IPsec VPN tunnels. Select a tunnel from the list and then select the right arrow.
Members	A list of tunnels that are members of the concentrator. To remove a tunnel from the concentrator, select the tunnel and select the left arrow.

IPsec Monitor

You can use the IPsec Monitor to view activity on IPsec VPN tunnels and start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels, including tunnel mode and route-based (interface mode) tunnels.

To view the IPsec monitor, go to **VPN > Monitor > IPsec Monitor**.

For dialup VPNs, the list provides status information about the VPN tunnels established by dialup clients, and their IP addresses.

For static IP or dynamic DNS VPNs, the list provides status and IP addressing information about VPN tunnels, active or not, to remote peers that have static IP addresses or domain names. You can also start and stop individual tunnels from the list.

Phase 1 parameters

This chapter provides detailed step-by-step procedures for configuring a FortiGate unit to accept a connection from a remote peer or dialup client. The Phase 1 parameters identify the remote peer or clients and supports authentication through preshared keys or digital certificates. You can increase access security further using peer identifiers, certificate distinguished names, group names, or the FortiGate extended authentication (XAuth) option for authentication purposes.

For more information on Phase 1 parameters in the web-based manager, see IPsec VPN in the web-based manager on page 1568.

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

The following topics are included in this section:

Overview
Defining the tunnel ends
Choosing Main mode or Aggressive mode
Choosing the IKE version
Authenticating the FortiGate unit
Authenticating remote peers and clients
Defining IKE negotiation parameters
Using XAuth authentication
Dynamic IPsec route control

Overview

To configure IPsec Phase 1 settings, go to **VPN > IPsec > Tunnels** and edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

IPsec Phase 1 settings define:

- The remote and local ends of the IPsec tunnel
- If Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information (main mode) or in a single message with authentication information that is not encrypted (aggressive mode)
- If a preshared key or digital certificates will be used to authenticate the FortiGate unit to the VPN peer or dialup client
- If the VPN peer or dialup client is required to authenticate to the FortiGate unit. A remote peer or dialup client can authenticate by peer ID or, if the FortiGate unit authenticates by certificate, it can authenticate by peer certificate.
- The IKE negotiation proposals for encryption and authentication
- Optional XAuth authentication, which requires the remote user to enter a user name and password. A FortiGate VPN server can act as an XAuth server to authenticate dialup users. A FortiGate unit that is a dialup client can also be configured as an XAuth client to authenticate itself to the VPN server.

For all the Phase 1 web-based manager fields, see IPsec VPN in the web-based manager on page 1568.

If you want to control how IKE is negotiated when there is no traffic, as well as the length of time the unit waits for negotiations to occur, use the `negotiation-timeout` and `auto-negotiate` commands in the CLI.

Defining the tunnel ends

To begin defining the Phase 1 configuration, go to **VPN > IPsec > Tunnels** and select **Create New**. Enter a unique descriptive name for the VPN tunnel and follow the instructions in the VPN Creation Wizard.

The Phase 1 configuration mainly defines the ends of the IPsec tunnel. The remote end is the remote gateway with which the FortiGate unit exchanges IPsec packets. The local end is the FortiGate interface that sends and receives IPsec packets.

The remote gateway can be:

- A static IP address
- A domain name with a dynamic IP address
- A dialup client

A statically addressed remote gateway is the simplest to configure. You specify the IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer has a domain name and subscribes to a dynamic DNS service, you need to specify only the domain name. The FortiGate unit performs a DNS query to determine the appropriate IP address. Unless restricted in the security policy, either the remote peer or a peer on the network behind the FortiGate unit can bring up the tunnel.

If the remote peer is a dialup client, only the dialup client can bring up the tunnel. The IP address of the client is not known until it connects to the FortiGate unit. This configuration is a typical way to provide a VPN for client PCs running VPN client software such as the FortiClient Endpoint Security application.

The local end of the VPN tunnel, the Local Interface, is the FortiGate interface that sends and receives the IPsec packets. This is usually the public interface of the FortiGate unit that is connected to the Internet (typically the WAN1 port). Packets from this interface pass to the private network through a security policy.

By default, the local VPN gateway is the IP address of the selected Local Interface. If you are configuring an interface mode VPN, you can optionally use a secondary IP address of the Local Interface as the local gateway.

Choosing Main mode or Aggressive mode

The FortiGate unit and the remote peer or dialup client exchange Phase 1 parameters in either Main mode or Aggressive mode. This choice does not apply if you use IKE version 2, which is available only for route-based configurations.

- In **Main** mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information
- In **Aggressive** mode, the Phase 1 parameters are exchanged in a single message with unencrypted authentication information.

Although Main mode is more secure, you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address, and the remote VPN peer or client is authenticated using an identifier local ID. Aggressive mode might not be as secure as Main mode, but the advantage to Aggressive mode is that it is faster than Main mode (since fewer packets are exchanged). Aggressive mode is typically used for remote access VPN's. But you would also use aggressive mode if one or both peers have dynamic external IP addresses. Descriptions of the peer options in this guide indicate whether Main or Aggressive mode is required.

Choosing the IKE version

If you create a route-based VPN, you have the option of selecting IKE version 2. Otherwise, IKE version 1 is used.

IKEv2, defined in RFC 4306, simplifies the negotiation process that creates the security association (SA).

If you select IKEv2:

- There is no choice in Phase 1 of Aggressive or Main mode.
- FortiOS does not support Peer Options or Local ID.
- Extended Authentication (XAUTH) is not available.
- You can select only one Diffie-Hellman Group.
- You can utilize EAP and MOBIKE.

IKEv2 cookie notification for IKE_SA_INIT

IKEv2 offers an optional exchange within IKE_SA_INIT (the initial exchange between peers when establishing a secure tunnel) as a reuslt of an inherent vulnerability in IPsec implementations, as described in RFC 5996.

Two expected attacks against IKE are state and CPU exhaustion, where the target is flooded with session initiation requests from forged IP addresses. These attacks can be made less effective if a responder uses minimal CPU and commits no state to an SA until it knows the initiator can receive packets at the address from which it claims to be sending them.

If the IKE_SA_INIT response includes the cookie notification, the initiator MUST then retry the IKE_SA_INIT request, and include the cookie notification containing the received data as the first payload, and all other payloads unchanged.

Upon detecting that the number of half-open IKEv2 SAs is above the threshold value, the VPN dialup server requires all future SA_INIT requests to include a valid cookie notification payload that the server sends back, in order to preserve CPU and memory resources.

For most devices, the threshold value is set to 500, half of the maximum 1,000 connections.

This feature is enabled by default in FortiOS 5.2.

Authenticating the FortiGate unit

The FortiGate unit can authenticate itself to remote peers or dialup clients using either a pre-shared key or an RSA Signature (certificate).

Authenticating the FortiGate unit with digital certificates

To authenticate the FortiGate unit using digital certificates, you must have the required certificates installed on the remote peer and on the FortiGate unit. The signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer. If you use certificates to authenticate the FortiGate unit, you can also require the remote peers or dialup clients to authenticate using certificates.

For more information about obtaining and installing certificates, see the FortiOS User Authentication guide.

To authenticate the FortiGate unit using digital certificates

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection. For interface mode, the name can be up to 15 characters long.
Remote Gateway	Select the nature of the remote connection. Each option changes the available fields you must configure. For more information, see Authenticating the FortiGate unit on page 1583.
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 1583. The local interface is typically the WAN1 port.
Mode	Select a mode. It is easier to use Aggressive mode. In **Main** mode, parameters are exchanged in multiple encrypted rounds. In **Aggressive** mode, parameters are exchanged in a single unencrypted message. Aggressive mode must be used when the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID). For more information, see Authenticating the FortiGate unit on page 1583.
Authentication Method	Select **Signature.**
Certificate Name	Select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must obtain and load the required server certificate before this selection. See the FortiOS User Authentication guide. If you have not loaded any certificates, use the certificate named **Fortinet_Factory**.
Peer Options	Peer options define the authentication requirements for remote peers or dialup clients. They are not for your FortiGate unit itself. See Authenticating the FortiGate unit on page 1583.
Advanced	You can use the default settings for most Phase 1 configurations. Changes are required only if your network requires them. These settings includes IKE version, DNS server, P1 proposal encryption and authentication settings, and XAuth settings. See Authenticating the FortiGate unit on page 1583.

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters in the Advanced section. See Authenticating the FortiGate unit on page 1583.
4. Select **OK**.

Authenticating the FortiGate unit with a pre-shared key

The simplest way to authenticate a FortiGate unit to its remote peers or dialup clients is by means of a pre-shared key. This is less secure than using certificates, especially if it is used alone, without requiring peer IDs or extended authentication (XAuth). Also, you need to have a secure way to distribute the pre-shared key to the peers.

If you use pre-shared key authentication alone, all remote peers and dialup clients must be configured with the same pre-shared key. Optionally, you can configure remote peers and dialup clients with unique pre-shared keys. On the FortiGate unit, these are configured in user accounts, not in the phase_1 settings. For more information, see Authenticating the FortiGate unit on page 1583.

The pre-shared key must contain at least 6 printable characters and best practices dictate that it be known only to network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.

If you authenticate the FortiGate unit using a pre-shared key, you can require remote peers or dialup clients to authenticate using peer IDs, but not client certificates.

To authenticate the FortiGate unit with a pre-shared key

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button):

Name	Enter a name that reflects the origination of the remote connection.
Remote Gateway	Select the nature of the remote connection. For more information, see Authenticating the FortiGate unit on page 1583.
Local Interface	Select the interface that is the local end of the IPsec tunnel. For more information, see Authenticating the FortiGate unit on page 1583. The local interface is typically the WAN1 port.
Mode	Select Main or Aggressive mode. In **Main** mode, the Phase 1 parameters are exchanged in multiple rounds with encrypted authentication information. In **Aggressive** mode, the Phase 1 parameters are exchanged in single message with authentication information that is not encrypted. When the remote VPN peer or client has a dynamic IP address, or the remote VPN peer or client will be authenticated using an identifier (local ID), you must select Aggressive mode if there is more than one dialup Phase 1 configuration for the interface IP address. For more information, see Authenticating the FortiGate unit on page 1583.
Authentication Method	Select **Pre-shared Key**.

Pre-shared Key	Enter the preshared key that the FortiGate unit will use to authenticate itself to the remote peer or dialup client during Phase 1 negotiations. You must define the same value at the remote peer or client. The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must consist of a minimum of 16 randomly chosen alphanumeric characters.
Peer options	Peer options define the authentication requirements for remote peers or dialup clients, not for the FortiGate unit itself. You can require the use of peer IDs, but not client certificates. For more information, see Authenticating the FortiGate unit on page 1583.
Advanced	You can retain the default settings unless changes are needed to meet your specific requirements. See Authenticating the FortiGate unit on page 1583.

3. If you are configuring authentication parameters for a dialup user group, optionally define extended authentication (XAuth) parameters. See Authenticating the FortiGate unit on page 1583.
4. Select **OK**.

Authenticating remote peers and clients

Certificates or pre-shared keys restrict who can access the VPN tunnel, but they do not identify or authenticate the remote peers or dialup clients. You have the following options for authentication:

Methods of authenticating remote VPN peers

Certificates or Pre-shared key	Local ID	User account pre-shared keys	Reference
Certificates			See Enabling VPN access for specific certificate holders on page 1587.
Either	**X**		See Enabling VPN access by peer identifier on page 1588.
Pre-shared key		**X**	See Enabling VPN access with user accounts and pre-shared keys on page 1589.
Pre-shared key	**X**	**X**	See Enabling VPN access with user accounts and pre-shared keys on page 1589.

For authentication of users of the remote peer or dialup client device, see Authenticating remote peers and clients on page 1586.

Enabling VPN access for specific certificate holders

When a VPN peer or dialup client is configured to authenticate using digital certificates, it sends the Distinguished Name (DN) of its certificate to the FortiGate unit. This DN can be used to allow VPN access for the certificate holder. That is, a FortiGate unit can be configured to deny connections to all remote peers and dialup clients except the one having the specified DN.

Before you begin

The following procedures assume that you already have an existing Phase 1 configuration (see Authenticating remote peers and clients on page 1586). Follow the procedures below to add certificate-based authentication parameters to the existing configuration.

Before you begin, you must obtain the certificate DN of the remote peer or dialup client. If you are using the FortiClient application as a dialup client, refer to FortiClient online help for information about how to view the certificate DN. To view the certificate DN of a FortiGate unit, see To view server certificate information and obtain the local DN on page 1587.

Use the `config user peer` CLI command to load the DN value into the FortiGate configuration. For example, if a remote VPN peer uses server certificates issued by your own organization, you would enter information similar to the following:

```
config user peer
   edit DN_FG1000
      set cn 192.168.2.160
      set cn-type ipv4
end
```

The value that you specify to identify the entry (for example, DN_FG1000) is displayed in the **Accept this peer certificate only** list in the IPsec Phase 1 configuration when you return to the web-based manager.

If the remote VPN peer has a CA-issued certificate to support a higher level of credibility, you would enter information similar to the following in the CLI:

```
config user peer
   edit CA_FG1000
      set ca CA_Cert_1
      set subject FG1000_at_site1
end
```

The value that you specify to identify the entry (for example, CA_FG1000) is displayed in the Accept this peer certificate only list in the IPsec Phase 1 configuration when you return to the web-based manager. For more information about these CLI commands, see the “user” chapter of the FortiGate CLI Reference.

A group of certificate holders can be created based on existing user accounts for dialup clients. To create the user accounts for dialup clients, see the “User” chapter of the FortiGate Administration Guide. To create the certificate group afterward, use the `config user peergrp` CLI command. See the “user” chapter of the FortiGate CLI Reference.

To view server certificate information and obtain the local DN

1. Go to **System > Certificates > Local Certificates**.
2. Note the CN value in the **Subject** field (for example, `CN = 172.16.10.125`, `CN = info@fortinet.com`, or `CN = www.example.com`).

To view CA root certificate information and obtain the CA certificate name

1. Go to **System > Certificates > CA Certificates**.
2. Note the value in the **Name** column (for example, `CA_Cert_1`).

Configuring certificate authentication for a VPN

With peer certificates loaded, peer users and peer groups defined, you can configure your VPN to authenticate users by certificate.

To enable access for a specific certificate holder or a group of certificate holders

1. At the FortiGate VPN server, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. From the **Authentication Method** list, select **RSA Signature**.
4. From the **Certificate Name** list, select the name of the server certificate that the FortiGate unit will use to authenticate itself to the remote peer or dialup client
5. Under **Peer Options**, select one of these options:
   - To accept a specific certificate holder, select **Accept this peer certificate only** and select the name of the certificate that belongs to the remote peer or dialup client. The certificate DN must be added to the FortiGate configuration through CLI commands before it can be selected here. See Before you begin on page 1587.
   - To accept dialup clients who are members of a certificate group, select **Accept this peer certificate group only** and select the name of the group. The group must be added to the FortiGate configuration through CLI commands before it can be selected here. See Before you begin on page 1587.
6. If you want the FortiGate VPN server to supply the DN of a local server certificate for authentication purposes, select **Advanced** and then from the **Local ID** list, select the DN of the certificate that the FortiGate VPN server is to use.
7. Select **OK**.

Enabling VPN access by peer identifier

Whether you use certificates or pre-shared keys to authenticate the FortiGate unit, you can require that remote peers or clients have a particular peer ID. This adds another piece of information that is required to gain access to the VPN. More than one FortiGate/FortiClient dialup client may connect through the same VPN tunnel when the dialup clients share a preshared key and assume the same identifier.

A peer ID, also called local ID, can be up to 63 characters long containing standard regular expression characters. Local ID is set in phase1 Aggressive Mode configuration.

You cannot require a peer ID for a remote peer or client that uses a pre-shared key and has a static IP address.

To authenticate remote peers or dialup clients using one peer ID

1. At the FortiGate VPN server, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Aggressive** mode in any of the following cases:
   - The FortiGate VPN server authenticates a FortiGate dialup client that uses a dedicated tunnel
   - A FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service

- FortiGate/FortiClient dialup clients sharing the same preshared key and local ID connect through the same VPN tunnel

4. For the **Peer Options**, select **This peer ID** and type the identifier into the corresponding field.
5. Select **OK**.

To assign an identifier (local ID) to a FortiGate unit

Use this procedure to assign a peer ID to a FortiGate unit that acts as a remote peer or dialup client.

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Advanced**.
4. In the **Local ID** field, type the identifier that the FortiGate unit will use to identify itself.
5. Set **Mode** to **Aggressive** if any of the following conditions apply:
   - The FortiGate unit is a dialup client that will use a unique ID to connect to a FortiGate dialup server through a dedicated tunnel.
   - The FortiGate unit has a dynamic IP address, subscribes to a dynamic DNS service, and will use a unique ID to connect to the remote VPN peer through a dedicated tunnel.
   - The FortiGate unit is a dialup client that shares the specified ID with multiple dialup clients to connect to a FortiGate dialup server through the same tunnel.
6. Select **OK**.

To configure the FortiClient application

Follow this procedure to add a peer ID to an existing FortiClient configuration:

1. Start the FortiClient application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit > Advanced**.
4. Under **Policy**, select **Config**.
5. In the **Local ID** field, type the identifier that will be shared by all dialup clients. This value must match the **This peer ID** value that you specified previously in the Phase 1 gateway configuration on the FortiGate unit.
6. Select **OK** to close all dialog boxes.
7. Configure all dialup clients the same way using the same preshared key and local ID.

Enabling VPN access with user accounts and pre-shared keys

You can permit access only to remote peers or dialup clients that have pre-shared keys and/or peer IDs configured in user accounts on the FortiGate unit.

If you want two VPN peers (or a FortiGate unit and a dialup client) to accept reciprocal connections based on peer IDs, you must enable the exchange of their identifiers when you define the Phase 1 parameters.

The following procedures assume that you already have an existing Phase 1 configuration (see Authenticating remote peers and clients on page 1586). Follow the procedures below to add ID checking to the existing configuration.

Before you begin, you must obtain the identifier (local ID) of the remote peer or dialup client. If you are using the FortiClient Endpoint Security application as a dialup client, refer to the Authenticating FortiClient Dialup Clients Technical Note to view or assign an identifier. To assign an identifier to a FortiGate dialup client or a FortiGate

unit that has a dynamic IP address and subscribes to a dynamic DNS service, see To assign an identifier (local ID) to a FortiGate unit on page 1589.

If required, a dialup user group can be created from existing user accounts for dialup clients. To create the user accounts and user groups, see the User Authentication handbook chapter.

The following procedure supports FortiGate/FortiClient dialup clients that use unique preshared keys and/or peer IDs. The client must have an account on the FortiGate unit and be a member of the dialup user group.

The dialup user group must be added to the FortiGate configuration before it can be selected. For more information, see the User Authentication handbook chapter.

The FortiGate dialup server compares the local ID that you specify at each dialup client to the FortiGate user-account user name. The dialup-client preshared key is compared to a FortiGate user-account password.

To authenticate dialup clients using unique preshared keys and/or peer IDs

1. At the FortiGate VPN server, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. If the clients have unique peer IDs, set **Mode** to **Aggressive**.
4. Clear the **Pre-shared Key** field.
   The user account password will be used as the preshared key.
5. Select **Peer ID from dialup group** and then select the group name from the list of user groups.
6. Select **OK**.

Follow this procedure to add a unique pre-shared key and unique peer ID to an existing FortiClient configuration.

To configure FortiClient - pre-shared key and peer ID

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration.
3. Select **Advanced > Edit**.
4. In the **Preshared Key** field, type the FortiGate password that belongs to the dialup client (for example, `1234546`).
   The user account password will be used as the preshared key.
5. Select **Advanced**.
6. Under **Policy**, select **Config**.
7. In the **Local ID** field, type the FortiGate user name that you assigned previously to the dialup client (for example, `FortiClient1`).
8. Select **OK** to close all dialog boxes.

Configure all FortiClient dialup clients this way using unique preshared keys and local IDs.

Follow this procedure to add a unique pre-shared key to an existing FortiClient configuration.

To configure FortiClient - preshared key only

1. Start the FortiClient Endpoint Security application.
2. Go to **VPN > Connections**, select the existing configuration
3. Select **Advanced > Edit**.

4. In the **Preshared Key** field, type the user name, followed by a "+" sign, followed by the password that you specified previously in the user account settings on the FortiGate unit (for example, `FC2+1FG6LK`)
5. Select **OK** to close all dialog boxes.

Configure all the FortiClient dialup clients this way using their unique peer ID and pre-shared key values.

Defining IKE negotiation parameters

In Phase 1, the two peers exchange keys to establish a secure communication channel between them. As part of the Phase 1 process, the two peers authenticate each other and negotiate a way to encrypt further communications for the duration of the session. For more information see Defining IKE negotiation parameters on page 1591. The Phase 1 Proposal parameters select the encryption and authentication algorithms that are used to generate keys for protecting negotiations.

The IKE negotiation parameters determine:

- Which encryption algorithms may be applied for converting messages into a form that only the intended recipient can read
- Which authentication hash may be used for creating a keyed hash from a preshared or private key
- Which Diffie-Hellman group (DH Group) will be used to generate a secret session key

Phase 1 negotiations (in main mode or aggressive mode) begin as soon as a remote VPN peer or client attempts to establish a connection with the FortiGate unit. Initially, the remote peer or dialup client sends the FortiGate unit a list of potential cryptographic parameters along with a session ID. The FortiGate unit compares those parameters to its own list of advanced Phase 1 parameters and responds with its choice of matching parameters to use for authenticating and encrypting packets. The two peers handle the exchange of encryption keys between them, and authenticate the exchange through a preshared key or a digital signature.

Generating keys to authenticate an exchange

The FortiGate unit supports the generation of secret session keys automatically using a Diffie-Hellman algorithm. These algorithms are defined in RFC 2409. The **Keylife** setting in the **Phase 1 Proposal** area determines the amount of time before the Phase 1 key expires. Phase 1 negotiations are re-keyed automatically when there is an active security association. See Dead peer detection on page 1594.

You can enable or disable automatic re-keying between IKE peers through the `phase1-rekey` attribute of the `config system global` CLI command. For more information, see the "System" chapter of the FortiGate CLI Reference.

When in FIPS-CC mode, the FortiGate unit requires DH key exchange to use values at least 3072 bits long. However most browsers need the key size set to 1024. You can set the minimum size of the DH keys in the CLI.

```
config system global
     set dh-params 3072
end
```

When you use a preshared key (shared secret) to set up two-party authentication, the remote VPN peer or client and the FortiGate unit must both be configured with the same preshared key. Each party uses a session key derived from the Diffie-Hellman exchange to create an authentication key, which is used to sign a known combination of inputs using an authentication algorithm (such as HMAC-MD5, HMAC-SHA-1, or HMAC-SHA-256). Hash-based Message Authentication Code (HMAC) is a method for calculating an authentication code

using a hash function plus a secret key, and is defined in RFC 2104. Each party signs a different combination of inputs and the other party verifies that the same result can be computed.

For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.

When you use preshared keys to authenticate VPN peers or clients, you must distribute matching information to all VPN peers and/or clients whenever the preshared key changes.

As an alternative, the remote peer or dialup client and FortiGate unit can exchange digital signatures to validate each other's identity with respect to their public keys. In this case, the required digital certificates must be installed on the remote peer and on the FortiGate unit. By exchanging certificate DNs, the signed server certificate on one peer is validated by the presence of the root certificate installed on the other peer.

The following procedure assumes that you already have a Phase 1 definition that describes how remote VPN peers and clients will be authenticated when they attempt to connect to a local FortiGate unit. For information about the Local ID and XAuth options, see Defining IKE negotiation parameters on page 1591 and Defining IKE negotiation parameters on page 1591. Follow this procedure to add IKE negotiation parameters to the existing definition.

Defining IKE negotiation parameters

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Phase 1 Proposal** and include the appropriate entries as follows:

Phase 1 Proposal	Select the encryption and authentication algorithms that will be used to generate keys for protecting negotiations. Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define. It is invalid to set both **Encryption** and **Authentication** to null.
Encryption	Select a symmetric-key algorithms: **NULL** — Do not use an encryption algorithm. **DES** — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. **3DES** — Triple-DES; plain text is encrypted three times by three keys. **AES128** — A 128-bit block algorithm that uses a 128-bit key. **AES192** — A 128-bit block algorithm that uses a 192-bit key. **AES256** — A 128-bit block algorithm that uses a 256-bit key.

Authentication	You can select either of the following message digests to check the authenticity of messages during an encrypted session: **NULL** — Do not use a message digest. **MD5** — Message Digest 5. **SHA1** — Secure Hash Algorithm 1 - a 160-bit message digest. To specify one combination only, set the **Encryption** and **Authentication** options of the second combination to NULL. To specify a third combination, use the **Add** button beside the fields for the second combination. For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.
Diffie-Hellman Group	Select one or more Diffie-Hellman groups from DH groups 1, 2, 5, and 14 through 21. When using aggressive mode, DH groups cannot be negotiated. By default, DH group 14 is selected, to provide sufficient protection for stronger cipher suites that include AES and SHA2. If you select multiple DH groups, the order they appear in the configuration is the order in which they are negotiates. If both VPN peers (or a VPN server and its client) have static IP addresses and use aggressive mode, select a single DH group. The setting on the FortiGate unit must be identical to the setting on the remote peer or dialup client. When the remote VPN peer or client has a dynamic IP address and uses aggressive mode, select up to three DH groups on the FortiGate unit and one DH group on the remote peer or dialup client. The setting on the remote peer or dialup client must be identical to one of the selections on the FortiGate unit. If the VPN peer or client employs main mode, you can select multiple DH groups. At least one of the settings on the remote peer or dialup client must be identical to the selections on the FortiGate unit.
Keylife	Type the amount of time (in seconds) that will be allowed to pass before the IKE encryption key expires. When the key expires, a new key is generated without interrupting service. The keylife can be from 120 to 172800 seconds.
Nat-traversal	Enable this option if a NAT device exists between the local FortiGate unit and the VPN peer or client. The local FortiGate unit and the VPN peer or client must have the same NAT traversal setting (both selected or both cleared). When in doubt, enable NAT-traversal. See NAT traversal on page 1594.
Keepalive Frequency	If you enabled NAT traversal, enter a keepalive frequency setting. The value represents an interval from 0 to 900 seconds where the connection will be maintained with no activity. For additional security this value must be as low as possible. See NAT keepalive frequency on page 1594.

Dead Peer Detection	Enable this option to reestablish VPN tunnels on idle connections and clean up dead IKE peers if required. This feature minimizes the traffic required to check if a VPN peer is available or unavailable (dead). See Dead peer detection on page 1594.

NAT traversal

Network Address Translation (NAT) is a way to convert private IP addresses to publicly routable Internet addresses and vise versa. When an IP packet passes through a NAT device, the source or destination address in the IP header is modified. FortiGate units support NAT version 1 (encapsulate on port 500 with non-IKE marker), version 3 (encapsulate on port 4500 with non-ESP marker), and compatible versions.

NAT cannot be performed on IPsec packets in ESP tunnel mode because the packets do not contain a port number. As a result, the packets cannot be demultiplexed. To work around this, the FortiGate unit provides a way to protect IPsec packet headers from NAT modifications. When the Nat-traversal option is enabled, outbound encrypted packets are wrapped inside a UDP IP header that contains a port number. This extra encapsulation allows NAT devices to change the port number without modifying the IPsec packet directly.

To provide the extra layer of encapsulation on IPsec packets, the Nat-traversal option must be enabled whenever a NAT device exists between two FortiGate VPN peers or a FortiGate unit and a dialup client such as FortiClient. On the receiving end, the FortiGate unit or FortiClient removes the extra layer of encapsulation before decrypting the packet.

NAT keepalive frequency

When a NAT device performs network address translation on a flow of packets, the NAT device determines how long the new address will remain valid if the flow of traffic stops (for example, the connected VPN peer may be idle). The device may reclaim and reuse a NAT address when a connection remains idle for too long.

To work around this, when you enable NAT traversal specify how often the FortiGate unit sends periodic keepalive packets through the NAT device in order to ensure that the NAT address mapping does not change during the lifetime of a session. To be effective, the keepalive interval must be smaller than the session lifetime value used by the NAT device.

The keepalive packet is a 138-byte ISAKMP exchange.

Dead peer detection

Sometimes, due to routing issues or other difficulties, the communication link between a FortiGate unit and a VPN peer or client may go down. Packets could be lost if the connection is left to time out on its own. The FortiGate unit provides a mechanism called Dead Peer Detection, sometimes referred to as gateway detection or ping server, to prevent this situation and reestablish IKE negotiations automatically before a connection times out: the active Phase 1 security associations are caught and renegotiated (rekeyed) before the Phase 1 encryption key expires.

By default, Dead Peer Detection sends probe messages every five seconds by default (see `dpd-retryinterval` in the FortiGate CLI Reference). If you are experiencing high network traffic, you can experiment with increasing the ping interval. However longer intervals will require more traffic to detect dead peers which will result in more traffic.

In the web-based manager, the Dead Peer Detection option can be enabled when you define advanced Phase 1 options. The `config vpn ipsec phase1` CLI command supports additional options for specifying a retry count and a retry interval.

For more information about these commands and the related `config router gwdetect` CLI command, see the FortiGate CLI Reference.

For example, enter the following CLI commands to configure dead peer detection on the existing IPsec Phase 1 configuration called `test` to use 15 second intervals and to wait for 3 missed attempts before declaring the peer dead and taking action.

```
config vpn ipsec phase1
   edit test
      set dpd enable
      set dpd-retryinveral 15
      set dpd-retrycount 3
   next
end
```

Using XAuth authentication

Extended authentication (XAuth) increases security by requiring the remote dialup client user to authenticate in a separate exchange at the end of Phase 1. XAuth draws on existing FortiGate user group definitions and uses established authentication mechanisms such as PAP, CHAP, RADIUS, and LDAP to authenticate dialup clients. You can configure a FortiGate unit to function either as an XAuth server or an XAuth client.If the server or client is attempting a connection using XAuth and the other end is not using XAuth, the failed connection attempts that are logged will not specify XAuth as the reason.

Using the FortiGate unit as an XAuth server

A FortiGate unit can act as an XAuth server for dialup clients. When the Phase 1 negotiation completes, the FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

If the user records on the RADIUS server have suitably configured Framed-IP-Address fields, you can assign client virtual IP addresses by XAuth instead of from a DHCP address range. See FortiClient dialup-client configurations on page 1654.

The authentication protocol to use for XAuth depends on the capabilities of the authentication server and the XAuth client:

- Select **PAP Server** whenever possible.
- You must select **PAP Server** for all implementations of LDAP and some implementations of Microsoft RADIUS.
- Select **Auto Server** when the authentication server supports **CHAP Server** but the XAuth client does not. The FortiGate unit will use PAP to communicate with the XAuth client and CHAP to communicate with the authentication server. You can also use **Auto Server** to allows multiple source interfaces to be defined in an IPsec/IKE policy

Before you begin, create user accounts and user groups to identify the dialup clients that need to access the network behind the FortiGate dialup server. If password protection will be provided through an external RADIUS or LDAP server, you must configure the FortiGate dialup server to forward authentication requests to the authentication server. For information about these topics, see the FortiGate User Authentication Guide.

To authenticate a dialup user group using XAuth settings

1. At the FortiGate dialup server, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the *Convert to Custom Tunnel* button).
3. Under **XAuth**, select the **Server Type** setting, which determines the type of encryption method to use between the XAuth client, the FortiGate unit and the authentication server. Select one of the following options:
   - **PAP Server** —Password Authentication Protocol.
   - **CHAP Server** — Challenge-Handshake Authentication Protocol.
   - **Auto Server** —Use PAP between the XAuth client and the FortiGate unit, and CHAP between the FortiGate unit and the authentication server. This option allows multiple source interfaces to be defined in an IPsec/IKE policy.
4. From the **User Group** list, select the user group that needs to access the private network behind the FortiGate unit. The group must be added to the FortiGate configuration before it can be selected here. For multiple source interfaces to be defined in the IPsec/IKE policy, select **Inherit Groups from Policy**.
5. Select **OK**.

Using the FortiGate unit as an XAuth client

If the FortiGate unit acts as a dialup client, the remote peer, acting as an XAuth server, might require a username and password. You can configure the FortiGate unit as an XAuth client, with its own username and password, which it provides when challenged.

To configure the FortiGate dialup client as an XAuth client

1. At the FortiGate dialup client, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Under **XAuth**, select **Enable as Client**.
4. In the **Username** field, type the FortiGate PAP, CHAP, RADIUS, or LDAP user name that the FortiGate XAuth server will compare to its records when the FortiGate XAuth client attempts to connect.
5. In the **Password** field, type the password to associate with the user name.
6. Select **OK**.

Dynamic IPsec route control

You can add a route to a peer destination selector by using the `add-route` option, which is available for all dynamic IPsec Phases 1 and 2, for both policy-based and route-based IPsec VPNs. This option was previously only available when `mode-cfg` was enabled in Phase 1.

The add-route option adds a route to the FortiGate unit's routing information base when the dynamic tunnel is negotiated. You can use the distance and priority options to set the distance and priority of this route. If this results in a route with the lowest distance, it is added to the FortiGate unit's forwarding information base.

You can also enable add-route in any policy-based or route-based Phase 2 configuration that is associated with a dynamic (dialup) Phase 1. In Phase 2, add-route can be enabled, disabled, or set to use the same route as Phase 1.

The add-route feature is enabled by default and is configured in the CLI.

Syntax

Phase 1

```
config vpn ipsec
   edit <name>
      set type dynamic
      set add-route {enable | disable}
   end
end
```

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
   edit <name>
      set add-route {phase1 | enable | disable}
   end
end
```

Blocking IPsec SA Negotiation

For interface-based IPsec, IPsec SA negotiation blocking can only be removed if the peer offers a wildcard selector. If a wildcard selector is offered then the wildcard route will be added to the routing table with the distance/priority value configured in Phase 1 and, if that is the route with the lowest distance, it is installed into the forwarding information base.

In cases where this occurs, it is important to ensure that the distance value configured on Phase 1 is set appropriately.

Phase 2 parameters

This section describes the Phase 2 parameters that are required to establish communication through a VPN.

The following topics are included in this section:

Phase 2 settings
Configuring the Phase 2 parameters

Phase 2 settings

After IPsec VPN Phase 1 negotiations complete successfully, Phase 2 negotiation begins. Phase 2 parameters define the algorithms that the FortiGate unit can use to encrypt and transfer data for the remainder of the session. The basic Phase 2 settings associate IPsec Phase 2 parameters with a Phase 1 configuration.

When defining Phase 2 parameters, you can choose any set of Phase 1 parameters to set up a secure connection and authenticate the remote peer.

For more information on Phase 2 settings in the web-based manager, see IPsec VPN in the web-based manager on page 1568.

The information and procedures in this section do not apply to VPN peers that perform negotiations using manual keys.

Phase 2 Proposals

In Phase 2, the VPN peer or client and the FortiGate unit exchange keys again to establish a secure communication channel. The Phase 2 Proposal parameters select the encryption and authentication algorithms needed to generate keys for protecting the implementation details of Security Associations (SAs). The keys are generated automatically using a Diffie-Hellman algorithm.

Replay Detection

IPsec tunnels can be vulnerable to replay attacks. Replay Detection enables the FortiGate unit to check all IPsec packets to see if they have been received before. If any encrypted packets arrive out of order, the FortiGate unit discards them.

Perfect Forward Secrecy (PFS)

By default, Phase 2 keys are derived from the session key created in Phase 1. Perfect Forward Secrecy (PFS) forces a new Diffie-Hellman exchange when the tunnel starts and whenever the Phase 2 keylife expires, causing a new key to be generated each time. This exchange ensures that the keys created in Phase 2 are unrelated to the Phase 1 keys or any other keys generated automatically in Phase 2.

Keylife

The Keylife setting sets a limit on the length of time that a Phase 2 key can be used. The default units are seconds. Alternatively, you can set a limit on the number of kilobytes (KB) of processed data, or both. If you select both, the key expires when either the time has passed or the number of KB have been processed. When the Phase 2 key expires, a new key is generated without interrupting service.

Quick mode selectors

Quick mode selectors determine which IP addresses can perform IKE negotiations to establish a tunnel. By only allowing authorized IP addresses access to the VPN tunnel, the network is more secure.

The default settings are as broad as possible: any IP address or configured address object, using any protocol, on any port.

While the drop down menus for specifying an address also show address groups, the use of address groups may not be supported on a remote endpoint device that is not a FortiGate.

The address groups are at the bottom of the list to make it easy to distinguish between addresses and address groups.

When configuring Quick Mode selector **Source address** and **Destination address**, valid options include IPv4 and IPv6 single addresses, IPv4 subnet, or IPv6 subnet. For more information on IPv6 IPsec VPN, see IPv6 IPsec VPNs on page 1717.

There are some configurations that require specific selectors:

- The VPN peer is a third-party device that uses specific phase2 selectors.
- The FortiGate unit connects as a dialup client to another FortiGate unit, in which case (usually) you must specify a source IP address, IP address range, or subnet. However, this is not required if you are using dynamic routing and mode-cfg.

With FortiOS VPNs, your network has multiple layers of security, with quick mode selectors being an important line of defence.

- Routes guide traffic from one IP address to another.
- Phase 1 and Phase 2 connection settings ensure there is a valid remote end point for the VPN tunnel that agrees on the encryption and parameters.
- Quick mode selectors allow IKE negotiations only for allowed peers.
- Security policies control which IP addresses can connect to the VPN.
- Security policies also control what protocols are allowed over the VPN along with any bandwidth limiting.

FortiOS is limited with IKEv2 selector matching. When using IKEv2 with a named traffic selector, no more than 32 subnets per traffic selector are added, since FortiOS doesn't fully implement the IKEv2 selector matching rules.

The workaround is to use multiple Phase 2s. If the configuration is FGT <-> FGT, then the better alternative is to just use 0.0.0.0 <-> 0.0.0.0 and use the firewall policy for enforcement.

Using the add-route option

Consider using the `add-route` option to add a route to a peer destination selector. Phase 2 includes the option of allowing the `add-route` to automatically match the settings in Phase 1. For more information, refer to Phase 1 parameters on page 1581.

Syntax

Phase 2

```
config vpn ipsec {phase2 | phase2-interface}
   edit <name>
      set add-route {phase1 | enable | disable}
   end
end
```

Configuring the Phase 2 parameters

If you are creating a hub-and-spoke configuration or an Internet-browsing configuration, you may have already started defining some of the required Phase 2 parameters. If so, edit the existing definition to complete the configuration.

Specifying the Phase 2 parameters

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter a **Name** for the Phase 2 configuration, and select a **Phase 1** configuration from the drop-down list.
4. Select **Advanced**.
5. Include the appropriate entries as follows:

Phase 2 Proposal	Select the encryption and authentication algorithms that will be used to change data into encrypted code. Add or delete encryption and authentication algorithms as required. Select a minimum of one and a maximum of three combinations. The remote peer must be configured to use at least one of the proposals that you define. It is invalid to set both **Encryption** and **Authentication** to null.
Encryption	Select a symmetric-key algorithms: **NULL** — Do not use an encryption algorithm. **DES** — Digital Encryption Standard, a 64-bit block algorithm that uses a 56-bit key. **3DES** — Triple-DES; plain text is encrypted three times by three keys. **AES128** — A 128-bit block algorithm that uses a 128-bit key. **AES192** — A 128-bit block algorithm that uses a 192-bit key. **AES256** — A 128-bit block algorithm that uses a 256-bit key.

Authentication	You can select either of the following message digests to check the authenticity of messages during an encrypted session: **NULL** — Do not use a message digest. **MD5** — Message Digest 5. **SHA1** — Secure Hash Algorithm 1 - a 160-bit message digest. To specify one combination only, set the **Encryption** and **Authentication** options of the second combination to NULL. To specify a third combination, use the ***Add*** button beside the fields for the second combination. For information regarding NP accelerated offloading of IPsec VPN authentication algorithms, please refer to the Hardware Acceleration handbook chapter.
Enable replay detection	Optionally enable or disable replay detection. Replay attacks occur when an unauthorized party intercepts a series of IPsec packets and replays them back into the tunnel.
Enable perfect forward secrecy (PFS)	Enable or disable PFS. Perfect forward secrecy (PFS) improves security by forcing a new Diffie-Hellman exchange whenever keylife expires.
Diffie-Hellman Group	Select one Diffie-Hellman group (1, 2, 5, or 14 through 21). The remote peer or dialup client must be configured to use the same group.
Keylife	Select the method for determining when the Phase 2 key expires: **Seconds**, **KBytes**, or **Both**. If you select **Both**, the key expires when either the time has passed or the number of KB have been processed. The range is from 120 to 172800 seconds, or from 5120 to 2147483648 KB.
Autokey Keep Alive	Enable the option if you want the tunnel to remain active when no data is being processed.
Auto-negotiate	Enable the option if you want the tunnel to be automatically renegotiated when the tunnel expires.
DHCP-IPsec	Select **Enable** if the FortiGate unit acts as a dialup server and FortiGate DHCP server or relay will be used to assign VIP addresses to FortiClient dialup clients. The DHCP server or relay parameters must be configured separately. If the FortiGate unit acts as a dialup server and the FortiClient dialup client VIP addresses match the network behind the dialup server, select **Enable** to cause the FortiGate unit to act as a proxy for the dialup clients. This is available only for Phase 2 configurations associated with a dialup Phase 1 configuration. It works only on policy-based VPNs.

Autokey Keep Alive

The Phase 2 SA has a fixed duration. If there is traffic on the VPN as the SA nears expiry, a new SA is negotiated and the VPN switches to the new SA without interruption. If there is no traffic, however, the SA expires (by default) and the VPN tunnel goes down. A new SA will not be generated until there is traffic.

The Autokey Keep Alive option ensures that a new Phase 2 SA is negotiated, even if there is no traffic, so that the VPN tunnel stays up.

Auto-negotiate

By default, the Phase 2 security association (SA) is not negotiated until a peer attempts to send data. The triggering packet and some subsequent packets are dropped until the SA is established. Applications normally resend this data, so there is no loss, but there might be a noticeable delay in response to the user.

If the tunnel goes down, the auto-negotiate feature (when enabled) attempts to re-establish the tunnel. Auto-negotiate initiates the Phase 2 SA negotiation automatically, repeating every five seconds until the SA is established.

Automatically establishing the SA can be important for a dialup peer. It ensures that the VPN tunnel is available for peers at the server end to initiate traffic to the dialup peer. Otherwise, the VPN tunnel does not exist until the dialup peer initiates traffic.

The auto-negotiate feature is available through the Command Line Interface (CLI) via the following commands:

```
config vpn ipsec phase2
   edit <phase2_name>
      set auto-negotiate enable
   end
```

DHCP-IPsec

Select this option if the FortiGate unit assigns VIP addresses to FortiClient dialup clients through a DHCP server or relay. This option is available only if the Remote Gateway in the Phase 1 configuration is set to Dialup User and it works only on policy-based VPNs.

With the DHCP-IPsec option, the FortiGate dialup server acts as a proxy for FortiClient dialup clients that have VIP addresses on the subnet of the private network behind the FortiGate unit. In this case, the FortiGate dialup server acts as a proxy on the local private network for the FortiClient dialup client. When a host on the network behind the dialup server issues an ARP request that corresponds to the device MAC address of the FortiClient host (when a remote server sends an ARP to the local FortiClient dialup client), the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel.

This feature prevents the VIP address assigned to the FortiClient dialup client from causing possible arp broadcast problems — the normal and VIP addresses can confuse some network switches by two addresses having the same MAC address.

Defining VPN security policies

This section explains how to specify the source and destination IP addresses of traffic transmitted through an IPsec VPN, and how to define appropriate security policies.

The following topics are included in this section:

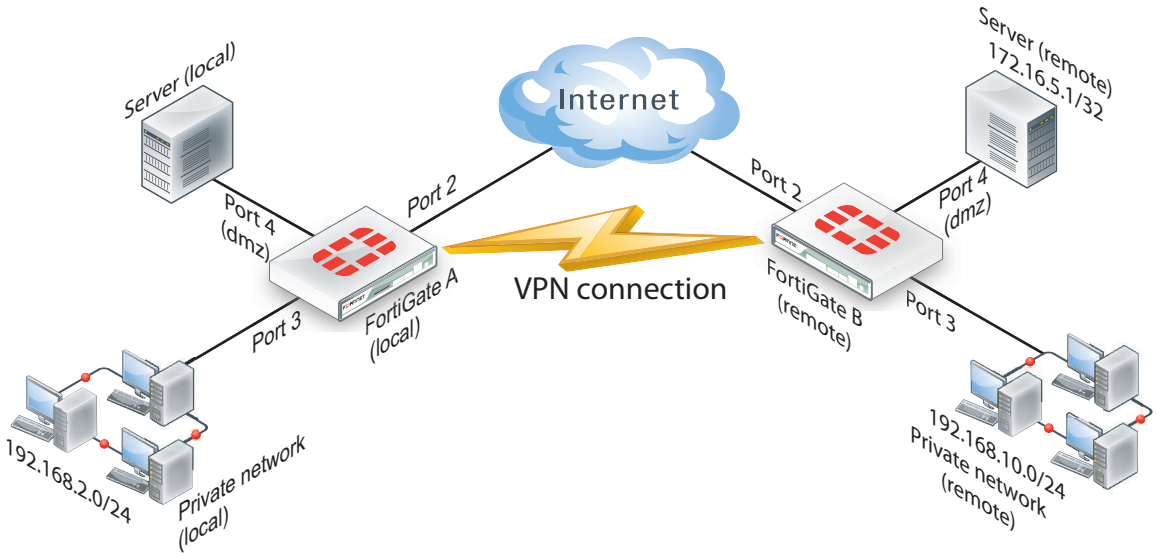
Defining policy addresses
Defining VPN security policies

Defining policy addresses

A VPN tunnel has two end points. These end points may be VPN peers such as two FortiGate gateways. Encrypted packets are transmitted between the end points. At each end of the VPN tunnel, a VPN peer intercepts encrypted packets, decrypts the packets, and forwards the decrypted IP packets to the intended destination.

You need to define firewall addresses for the private networks behind each peer. You will use these addresses as the source or destination address depending on the security policy.

Example topology for the following policies



In general:

- In a gateway-to-gateway, hub-and-spoke, dynamic DNS, redundant-tunnel, or transparent configuration, you need to define a policy address for the private IP address of the network behind the remote VPN peer (for example, `192.168.10.0/255.255.255.0` or `192.168.10.0/24`).
- In a peer-to-peer configuration, you need to define a policy address for the private IP address of a server or host behind the remote VPN peer (for example, `172.16.5.1/255.255.255.255` or `172.16.5.1/32` or `172.16.5.1`).

For a FortiGate dialup server in a dialup-client or Internet-browsing configuration:

- If you are not using VIP addresses, or if the FortiGate dialup server assigns VIP addresses to FortiClient dialup clients through FortiGate DHCP relay, select the predefined destination address “all” in the security policy to refer to the dialup clients.
- If you assign VIP addresses to FortiClient dialup clients manually, you need to define a policy address for the VIP address assigned to the dialup client (for example, `10.254.254.1/32`), or a subnet address from which the VIP addresses are assigned (for example, `10.254.254.0/24` or `10.254.254.0/255.255.255.0`).
- For a FortiGate dialup client in a dialup-client or Internet-browsing configuration, you need to define a policy address for the private IP address of a host, server, or network behind the FortiGate dialup server.

To define a security IP address

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. In the **Name** field, type a descriptive name that represents the network, server(s), or host(s).
3. In **Type**, select **Subnet**.
4. In the **Subnet/IP Range** field, type the corresponding IP address and subnet mask.
   For a subnet you could use the format `172.16.5.0/24` or its equivalent `172.16.5.0/255.255.255.0`. For a server or host it would likely be `172.16.5.1/32`. Alternately you can use an IP address range such as `192.168.10.[80-100]` or `192.168.10.80-192.168.10.100`.
5. Select **OK**.

Defining VPN security policies

Security policies allow IP traffic to pass between interfaces on a FortiGate unit. You can limit communication to particular traffic by specifying source address and destination addresses. Then only traffic from those addresses will be allowed.

Policy-based and route-based VPNs require different security policies.

- A policy-based VPN requires an IPsec security policy. You specify the interface to the private network, the interface to the remote peer and the VPN tunnel. A single policy can enable traffic inbound, outbound, or in both directions.
- A route-based VPN requires an Accept security policy for each direction. As source and destination interfaces, you specify the interface to the private network and the virtual IPsec interface (Phase 1 configuration) of the VPN. The IPsec interface is the destination interface for the outbound policy and the source interface for the inbound policy. One security policy must be configured for each direction of each VPN interface.

There are examples of security policies for both policy-based and route-based VPNs throughout this guide. See Dynamic DNS configuration on page 1639.

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won’t be able to retrieve a lease from the FortiGate’s (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Defining an IPsec security policy for a policy-based VPN

An IPsec security policy enables the transmission and reception of encrypted packets, specifies the permitted direction of VPN traffic, and selects the VPN tunnel. In most cases, a single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Allow traffic to be initiated from the remote site

In addition to these operations, security policies specify which IP addresses can initiate a tunnel. by default, traffic from the local private network initiates the tunnel. When the **Allow traffic to be initiated form the remote site** option is selected, traffic from a dialup client or computers on the remote network initiates the tunnel. Both can be enabled at the same time for bi-directional initiation of the tunnel.

Outbound and inbound NAT

When a FortiGate unit operates in NAT mode, you can also enable inbound or outbound NAT. Outbound NAT may be performed on outbound encrypted packets, or on IP packets before they are sent through the tunnel. Inbound NAT is performed on IP packets emerging from the tunnel. By default, these options are not selected in security policies.

When used in conjunction with the `natip` CLI attribute (see the “config firewall” chapter of the FortiGate CLI Reference), outbound NAT enables you to change the source addresses of IP packets before they go into the tunnel. This feature is often used to resolve ambiguous routing when two or more of the private networks making up a VPN have the same or overlapping IP addresses. .

When inbound NAT is enabled, inbound encrypted packets are intercepted and decrypted, and the source IP addresses of the decrypted packets are translated into the IP address of the FortiGate interface to the local private network before they are routed to the private network. If the computers on the local private network can communicate only with devices on the local private network (that is, the FortiGate interface to the private network is not the default gateway) and the remote client (or remote private network) does not have an IP address in the same network address space as the local private network, enable inbound NAT.

Source and destination addresses

Most security policies control outbound IP traffic. A VPN outbound policy usually has a source address originating on the private network behind the local FortiGate unit, and a destination address belonging to a dialup VPN client or a network behind the remote VPN peer. The source address that you choose for the security policy identifies from where outbound cleartext IP packets may originate, and also defines the local IP address or addresses that a remote server or client will be allowed to access through the VPN tunnel. The destination address that you choose identifies where IP packets must be forwarded after they are decrypted at the far end of the tunnel, and determines the IP address or addresses that the local network will be able to access at the far end of the tunnel.

Enabling other policy features

You can fine-tune a policy for services such as HTTP, FTP, and POP3; enable logging, traffic shaping, antivirus protection, web filtering, email filtering, file transfer, and email services throughout the VPN; and optionally allow connections according to a predefined schedule.

As an option, differentiated services (diffserv or DSCP) can be enabled in the security policy through CLI commands. For more information on this feature, see the Traffic Shaping handbook chapter, or the “firewall” chapter of the FortiGate CLI Reference.

When a remote server or client attempts to connect to the private network behind a FortiGate gateway, the security policy intercepts the connection attempt and starts the VPN tunnel. The FortiGate unit uses the remote gateway specified in its Phase 1 tunnel configuration to reply to the remote peer. When the remote peer receives a reply, it checks its own security policy, including the tunnel configuration, to determine which communications are permitted. As long as one or more services are allowed through the VPN tunnel, the two peers begin to

negotiate the tunnel. To follow this negotiation in the web-based manager, go to **VPN > Monitor > IPsec Monitor**. There you will find a list of the VPN tunnels, their status, and the data flow both incoming and outgoing.

Before you begin

Before you define the IPsec policy, you must:

- Define the IP source and destination addresses. See Defining VPN security policies on page 1604.
- Specify the Phase 1 authentication parameters. See Phase 1 parameters on page 1581.
- Specify the Phase 2 parameters. See Phase 2 parameters on page 1598.

To define an IPsec security policy

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New** and set the following options:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	Select the name that corresponds to the local network, server(s), or host(s) from which IP packets may originate.
Outgoing Interface	Select the local interface to the external (public) network.
Destination Address	Select the name that corresponds to the remote network, server(s), or host (s) to which IP packets may be delivered.
Schedule	Keep the default setting (always) unless changes are needed to meet specific requirements.
Service	Keep the default setting (ANY) unless changes are needed to meet your specific requirements.
Allow traffic to be initiated from the remote site	Select if traffic from the remote network will be allowed to initiate the tunnel.

3. You may enable UTM features, and/or event logging, or select advanced settings to authenticate a user group, or shape traffic. For more information, see the Firewall handbook chapter.
4. Select **OK**.
5. Place the policy in the policy list above any other policies having similar source and destination addresses.

Defining multiple IPsec policies for the same tunnel

You must define at least one IPsec policy for each VPN tunnel. If the same remote server or client requires access to more than one network behind a local FortiGate unit, the FortiGate unit must be configured with an IPsec policy for each network. Multiple policies may be required to configure redundant connections to a remote destination or control access to different services at different times.

To ensure a secure connection, the FortiGate unit must evaluate IPSEC policies before ACCEPT and DENY security policies. Because the FortiGate unit reads policies starting at the top of the list, you must move all IPsec policies to the top of the list. When you define multiple IPsec policies for the same tunnel, you must reorder the IPsec policies that apply to the tunnel so that specific constraints can be evaluated before general constraints.

Adding multiple IPsec policies for the same VPN tunnel can cause conflicts if the policies specify similar source and destination addresses but have different settings for the same service. When policies overlap in this manner, the system may apply the wrong IPsec policy or the tunnel may fail.

For example, if you create two equivalent IPsec policies for two different tunnels, it does not matter which one comes first in the list of IPsec policies — the system will select the correct policy based on the specified source and destination addresses. If you create two different IPsec policies for the same tunnel (that is, the two policies treat traffic differently depending on the nature of the connection request), you might have to reorder the IPsec policies to ensure that the system selects the correct IPsec policy. Reordering is especially important when the source and destination addresses in both policies are similar (for example, if one policy specifies a subset of the IP addresses in another policy). In this case, place the IPsec policy having the most specific constraints at the top of the list so that it can be evaluated first.

Defining security policies for a route-based VPN

When you define a route-based VPN, you create a virtual IPsec interface on the physical interface that connects to the remote peer. You create ordinary Accept security policies to enable traffic between the IPsec interface and the interface that connects to the private network. This makes configuration simpler than for policy-based VPNs, which require IPsec security policies.

To define security policies for a route-based VPN

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New** and leave the **Policy Type** as **Firewall**, and the **Policy Subtype** as **Address**.
3. Define an ACCEPT security policy to permit communications between the local private network and the private network behind the remote peer. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select the address name that you defined for the private network behind this FortiGate unit.
Outgoing Interface	Select the IPsec Interface you configured.
Destination Address	Select the address name that you defined for the private network behind the remote peer.
Action	Select **ACCEPT**.
Enable NAT	Disable.

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

4. Select **Create New** and leave the **Policy Type** as **Firewall**, and the **Policy Subtype** as **Address**
5. Enter these settings in particular:

Incoming Interface	Select the IPsec Interface you configured.

Source Address	Select the address name that you defined for the private network behind the remote peer.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	Select the address name that you defined for the private network behind this FortiGate unit.
Action	Select ***ACCEPT***.
Enable NAT	Disable.

Gateway-to-gateway configurations

This section explains how to set up a basic gateway-to-gateway (site-to-site) IPsec VPN.

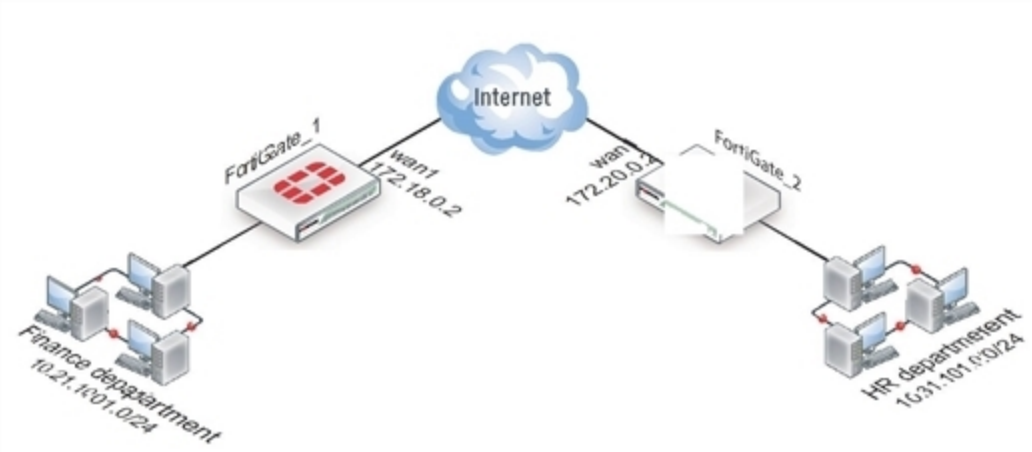
The following topics are included in this section:

Configuration overview
General configuration steps
Configuring the two VPN peers
How to work with overlapping subnets
Testing

Configuration overview

In a gateway-to-gateway configuration, two FortiGate units create a VPN tunnel between two separate private networks. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Example gateway-to-gateway configuration

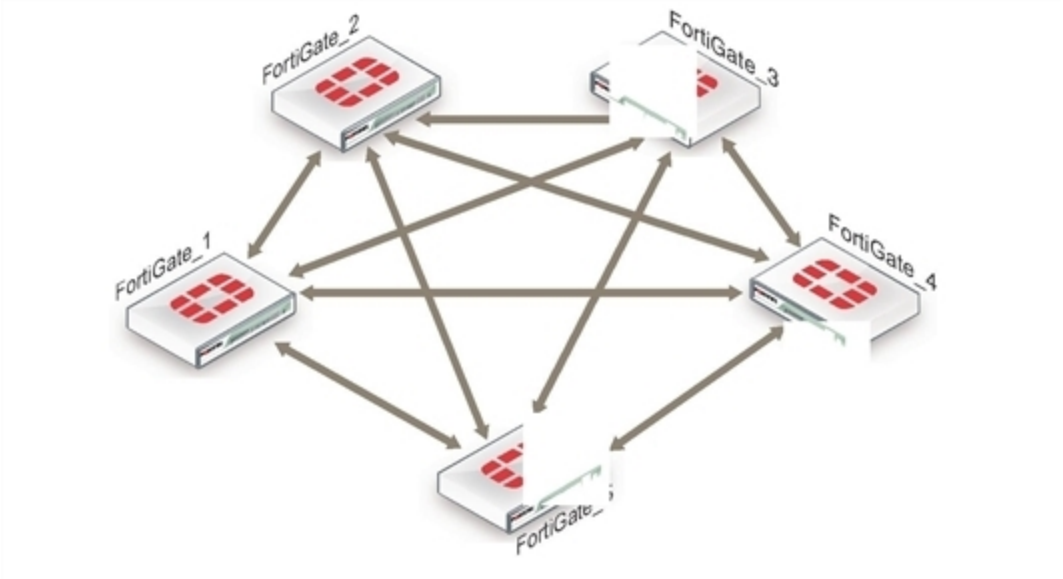


In some cases, computers on the private network behind one VPN peer may (by co-incidence) have IP addresses that are already used by computers on the network behind the other VPN peer. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent. To resolve issues related to ambiguous routing, see Configuration overview on page 1609.

In other cases, computers on the private network behind one VPN peer may obtain IP addresses from a local DHCP server. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and/or IP-address overlap issues may arise. For a discussion of the related issues, see FortiGate dialup-client configurations on page 1669.

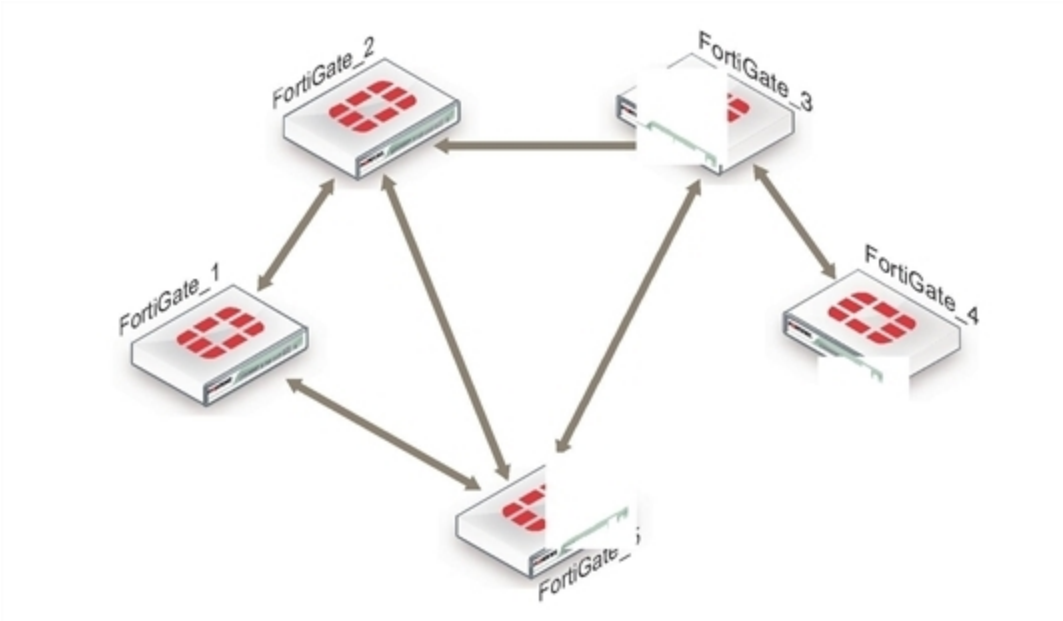
You can set up a fully meshed or partially meshed configuration (see below).

Fully meshed configuration



In a fully meshed network, all VPN peers are connected to each other, with one hop between peers. This topology is the most fault-tolerant: if one peer goes down, the rest of the network is not affected. This topology is difficult to scale because it requires connections between all peers. In addition, unnecessary communication can occur between peers. Best practices dictates a hub-and-spoke configuration instead (see Hub-and-spoke configurations on page 1623).

Partially meshed configuration



A partially meshed network is similar to a fully meshed network, but instead of having tunnels between all peers, tunnels are only configured between peers that communicate with each other regularly.

General configuration steps

The FortiGate units at both ends of the tunnel must be operating in NAT mode and have static public IP addresses.

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate that VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed by both FortiGate units:

- Define the Phase 1 parameters that the FortiGate unit needs to authenticate the remote peer and establish a secure connection.
- Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel with the remote peer.
- Create security policies to control the permitted services and permitted direction of traffic between the IP source and destination addresses.

Configuring the two VPN peers

Configure the VPN peers as follows. Each step is required, but these are general steps. For more detailed information on each step follow the cross references. See Phase 1 parameters on page 1581. All steps are required. Cross references point to required information that is repeated. No steps are optional.

Configuring Phase 1 and Phase 2 for both peers

This procedure applies to both peers. Repeat the procedure on each FortiGate unit, using the correct IP address for each. You may wish to vary the Phase 1 names but this is optional. Otherwise all steps are the same for each peer.

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate FortiGate_2 and establish a secure connection. For the purposes of this example, a preshared key will be used to authenticate FortiGate_2. The same preshared key must be specified at both FortiGate units.

Before you define the Phase 1 parameters, you need to:

- Reserve a name for the remote gateway.
- Obtain the IP address of the public interface to the remote peer.
- Reserve a unique value for the preshared key.

The key must contain at least 6 printable characters and best practices dictate that it only be known by network administrators. For optimum protection against currently known attacks, the key must have a minimum of 16 randomly chosen alphanumeric characters.

At the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the remote peer. See IPsec VPN in the web-based manager on page 1568.

To create Phase 1 to establish a secure connection with the remote peer

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**.

Name	Enter `peer_1`. A name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select **Static IP Address**.
IP Address	Enter `172.20.0.2` when configuring FortiGate_1. Enter `172.18.0.2` when configuring FortiGate_2. The IP address of the remote peer public interface.
Local Interface	Select **wan1**.

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end point of the VPN tunnel. Before you define the Phase 2 parameters, you need to reserve a name for the tunnel. See IPsec VPN in the web-based manager on page 1568.

To configure Phase 2 settings

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter a **Name** of `peer_1_p2`.
3. Select **peer_1** from the **Phase 1** drop-down menu.

Creating security policies

Security policies control all IP traffic passing between a source address and a destination address.

An IPsec security policy is needed to allow the transmission of encrypted packets, specify the permitted direction of VPN traffic, and select the VPN tunnel that will be subject to the policy. A single policy is needed to control both inbound and outbound IP traffic through a VPN tunnel.

Before you define security policies, you must first specify the IP source and destination addresses. In a gateway-to-gateway configuration:

- The IP source address corresponds to the private network behind the local FortiGate unit.
- The IP destination address refers to the private network behind the remote VPN peer.

When you are creating security policies, choose one of either route-based or policy-based methods and follow it for both VPN peers. DO NOT configure both route-based and policy-based policies on the same FortiGate unit for the same VPN tunnel.

The configuration of FortiGate_2 is similar to that of FortiGate_1. You must:

- Define the Phase 1 parameters that FortiGate_2 needs to authenticate FortiGate_1 and establish a secure connection.
- Define the Phase 2 parameters that FortiGate_2 needs to create a VPN tunnel with FortiGate_1.
- Create the security policy and define the scope of permitted services between the IP source and destination addresses.

When creating security policies it is good practice to include a comment describing what the policy does.

When creating security policies you need to be

- Creating firewall addresses
- Creating route-based VPN security policies
- Configuring a default route for VPN interface

or

- Creating firewall addresses
- Creating policy-based VPN security policy

Creating firewall addresses

Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks.

To define the IP address of the network behind FortiGate_1

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `Finance_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet** of `10.21.101.0/24`.
5. Select **OK**.

To specify the address of the network behind FortiGate_2

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. Enter the **Name** of `HR_network`.
3. Select a **Type** of **Subnet**.
4. Enter the **Subnet/IP Range** of `10.31.101.0/24`.
5. Select **OK**.

Creating route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

To create route-based VPN security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following, and select **OK**.

Incoming Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.

Source Address	Select **Finance_network** when configuring FortiGate_1. Select **HR_network** when configuring FortiGate_2. The address name for the private network behind this FortiGate unit.
Outgoing Interface	Select **peer_1**. The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address	Select **HR_network** when configuring FortiGate_1. Select **Finance_network** when configuring FortiGate_2. The address name that you defined for the private network behind the remote peer.
Action	Select **ACCEPT**.
Enable NAT	Disable.
Comments	Allow Internal to remote VPN network traffic.

4. Optionally, configure any additional features you may want, such as UTM or traffic shaping.
5. Select **Create New** to create another policy for the other direction.
6. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
7. Enter the following information, and select **OK**.

Incoming Interface	Select **peer_1**. The VPN Tunnel (IPsec Interface) you configured.
Source Address	Select **HR_network** when configuring FortiGate_1. Select **Finance_Network** when configuring FortiGate_2. The address name defined for the private network behind the remote peer.
Outgoing Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Destination Address	Select **Finance_Network** when configuring FortiGate_1. Select **HR_network** when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.
Action	Select **ACCEPT**.

Enable NAT	Disable.
Comments	Allow remote VPN network traffic to Internal.

8. Configure any additional features such as UTM or traffic shaping you may want. (optional).

Configuring a default route for VPN interface

All network traffic must have a static route to direct its traffic to the proper destination. Without a route, traffic will not flow even if the security policies are configured properly. You may need to create a static route entry for both directions of VPN traffic if your security policies allow bi-directional tunnel initiation.

To configure the route for a route-based VPN

1. On FortiGate_2, go to **Router > Static > Static Routes** and select **Create New**.

   For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.
2. Enter the following information, and then select **OK**:

Destination IP / Mask	10.21.101.0/24
Device	FGT2_to_FGT1_Tunnel
Gateway	Leave as default: 0.0.0.0.
Distance (Advanced)	Leave this at its default. If there are other routes on this FortiGate unit, you may need to set the distance on this route so the VPN traffic will use it as the default route. However, this normally happens by default because this route is typically a better match than the generic default route.

Creating policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Complete the following:

Incoming Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Source Address	Select **Finance_network** when configuring FortiGate_1. Select **HR_network** when configuring FortiGate_2. The address name defined for the private network behind this FortiGate unit.

Outgoing Interface	Select **wan1**. The FortiGate unit's public interface.
Destination Address	Select **HR_network** when configuring FortiGate_1. Select **Finance_network** when configuring FortiGate_2.
VPN Tunnel	Select **Use Existing** and select **peer_1** from the **VPN Tunnel** drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.
Comments	Bidirectional policy-based VPN policy.

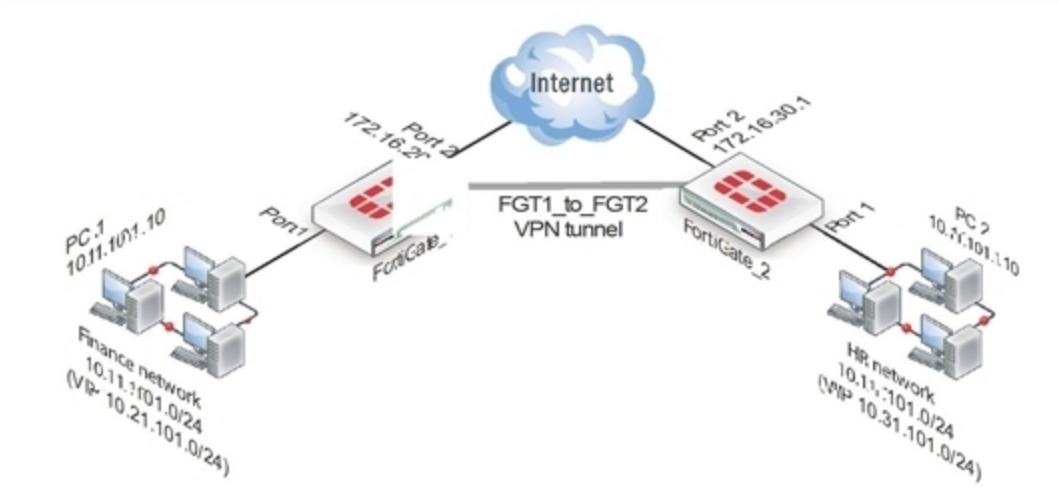
Place VPN policies in the policy list above any other policies having similar source and destination addresses.

How to work with overlapping subnets

A site-to-site VPN configuration sometimes has the problem that the private subnet addresses at each end are the same. You can resolve this problem by remapping the private addresses using virtual IP addresses (VIP).

VIPs allow computers on those overlapping private subnets to each have another set of IP addresses that can be used without confusion. The FortiGate unit maps the VIP addresses to the original addresses. This means if PC1 starts a session with PC2 at 10.31.101.10, FortiGate_2 directs that session to 10.11.101.10 — the actual IP address of PC2.The figure below demonstrates this — Finance network VIP is 10.21.101.0/24 and the HR network is 10.31.101.0/24.

Overlapped subnets example



Solution for route-based VPN

You need to:

- Configure IPsec Phase 1 and Phase 2 as you usually would for a route-based VPN. In this example, the resulting IPsec interface is named `FGT1_to_FGT2`.
- Configure virtual IP (VIP) mapping:
  - the 10.21.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_1
  - the 10.31.101.0/24 network mapped to the 10.11.101.0/24 network on FortiGate_2
- Configure an outgoing security policy with ordinary source NAT on both FortiGates.
- Configure an incoming security policy with the VIP as the destination on both FortiGates.
- Configure a route to the remote private network over the IPsec interface on both FortiGates.

To configure VIP mapping on both FortiGates

1. Go to **Policy & Objects > Objects > Virtual IPs** and select **Create New**.
2. Enter the following information, and select **OK**:

Name	Enter a name, for example, `my_vip`.
External Interface	Select `FGT1_to_FGT2`. The IPsec interface.
Type	Static NAT
External IP Address/Range	For the **External IP Address** field enter: `10.21.101.1` when configuring FortiGate_1, or `10.31.101.1` when configuring FortiGate_2.
Mapped IP Address/Range	For the **Mapped IP Address** enter `10.11.101.1`. For the **Range** enter `10.11.101.254`.
Port Forwarding	Disable

3. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the outbound security policy on both FortiGates

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**:

Incoming Interface	Select **Port 1**.
Source Address	Select **all**.
Outgoing Interface	Select **FGT1_to_FGT2**. The IPsec interface.
Destination Address	Select **all**.
Action	Select **ACCEPT**

Enable NAT	Enable

4. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the inbound security policy on both FortiGates

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and then select **OK**:

Incoming Interface	Select **FGT1_to_FGT2**.
Source Address	Select **all**.
Outgoing Interface	Select **Port 1**. The IPsec interface.
Destination Address	Select **my-vip**.
Action	Select **ACCEPT**
Enable NAT	Disable

4. Repeat this procedure on both FortiGate_1 and FortiGate_2.

To configure the static route for both FortiGates

1. Go to **Router > Static > Static Routes** and select **Create New**.

   For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.
2. Enter the following information, and then select **OK**:

Destination IP / Mask	Enter `10.31.101.0/24 when` configuring FortiGate_1. Enter `10.21.101.0/24` when configuring FortiGate_2.
Device	Select **FGT1_to_FGT2**.
Gateway	Leave as default: 0.0.0.0.
Distance (Advanced)	Leave at default. If you have advanced routing on your network, you may have to change this value

Solution for policy-based VPN

As with the route-based solution, users contact hosts at the other end of the VPN using an alternate subnet address. PC1 communicates with PC2 using IP address 10.31.101.10, and PC2 communicates with PC1 using IP address 10.21.101.10.

In this solution however, outbound NAT is used to translate the source address of packets from the 10.11.101.0/24 network to the alternate subnet address that hosts at the other end of the VPN use to reply. Inbound packets from the remote end have their destination addresses translated back to the 10.11.101.0/24 network.

For example, PC1 uses the destination address 10.31.101.10 to contact PC2. Outbound NAT on FortiGate_1 translates the PC1 source address to 10.21.101.10. At the FortiGate_2 end of the tunnel, the outbound NAT configuration translates the destination address to the actual PC2 address of 10.11.101.10. Similarly, PC2 replies to PC1 using destination address 10.21.101.10, with the PC2 source address translated to 10.31.101.10. PC1 and PC2 can communicate over the VPN even though they both have the same IP address.

- You need to:
- Configure IPsec Phase 1 as you usually would for a policy-based VPN.
- Configure IPsec Phase 2 with the `use-natip disable` CLI option.
- Define a firewall address for the local private network, 10.11.101.0/24.
- Define a firewall address for the remote private network:
  - Define a firewall address for 10.31.101.0/24 on FortiGate_1
  - Define a firewall address for 10.21.101.0/24 on FortiGate_2
- Configure an outgoing IPsec security policy with outbound NAT to map 10.11.101.0/24 source addresses:
  - To the 10.21.101.0/24 network on FortiGate_1
  - To the 10.31.101.0/24 network on FortiGate_2

To configure IPsec Phase 2 - CLI

```
config vpn ipsec phase2
   edit "FGT1_FGT2_p2"
      set keepalive enable
      set pfs enable
      set phase1name FGT1_to_FGT2
      set proposal 3des-sha1 3des-md5
      set replay enable
      set use-natip disable
   end
```

In this example, your Phase 1 definition is named FGT1_to_FGT2. `use-natip` is set to `disable`, so you can specify the source selector using the **`src-addr-type`**, `src-start-ip` / `src-end-ip` or `src-subnet` keywords. This example leaves these keywords at their default values, which specify the subnet `0.0.0.0/0`.

The `pfs` keyword ensures that perfect forward secrecy (PFS) is used. This ensures that each Phase 2 key created is unrelated to any other keys in use.

To define the local private network firewall address

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. Enter the following information and select **OK**.

Name	Enter `vpn-local`. A meaningful name for the local private network.
Type	Subnet
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	Any

To define the remote private network firewall address

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. Enter the following information, and select **OK**:

Name	Enter `vpn-remote`. A meaningful name for the remote private network.
Type	Subnet
Subnet / IP Range	`10.31.101.0 255.255.255.0` on FortiGate_1. `10.21.101.0 255.255.255.0` on FortiGate_2.
Interface	Any

To configure the IPsec security policy

In the CLI on FortiGate_1, enter the commands:

```
config firewall policy
   edit 1
      set srcintf "port1"
      set dstintf "port2"
      set srcaddr "vpn-local"
      set dstaddr "vpn-remote"
      set action ipsec
      set schedule "always"
      set service "ANY"
      set inbound enable
      set outbound enable
      set vpntunnel "FGT1_to_FGT2"
      set natoutbound enable
      set natip 10.31.101.0 255.255.255.0
   end
```

Optionally, you can set everything except `natip` in the web-based manager and then use the CLI to set `natip`.

Enter the same commands on FortiGate_2, but set natip be `10.21.101.0 255.255.255.0`.

Testing

The best testing is to look at the packets both as the VPN tunnel is negotiated, and when the tunnel is up.

To determine what the other end of the VPN tunnel is proposing

1. Start a terminal program such as puTTY and set it to log all output.

   When necessary refer to the logs to locate information when output is verbose.
2. Logon to the FortiGate unit using a super_admin account.
3. Enter the following CLI commands.
4. Display all the possible IKE error types and the number of times they have occurred:
   ```
   diag vpn ike errors
   ```
5. Check for existing debug sessions:
   ```
   diag debug info
   ```

If a debug session is running, to halt it enter:

```
diag debug disable
```

6. Confirm your proposal settings:
```
diag vpn ike config list
```
7. If your proposal settings do not match what you expect, make a change to it and save it to force an update in memory. If that fixes the problem, stop here.
8. List the current vpn filter:
```
diag vpn ike filter
```
9. If all fields are set to any, there are no filters set and all VPN IKE packets will be displayed in the debug output. If your system has only a few VPNs, skip setting the filter.

   If your system has many VPN connections this will result in very verbose output and make it very difficult to locate the correct connection attempt.
10. Set the VPN filter to display only information from the destination IP address for example 10.10.10.10:
```
diag vpn ike log-filter dst-addr4 10.10.10.10
```
    To add more filter options, enter them one per line as above. Other filter options are:

clear	erase the current filter
dst-addr6	the IPv6 destination address range to filter by
dst-port	the destination port range to filter by
interface	interface that IKE connection is negotiated over
list	display the current filter
name	the phase1 name to filter by
negate	negate the specified filter parameter
src-addr4	the IPv4 source address range to filter by
src-addr6	the IPv6 source address range to filter by
src-port	the source port range to filter by
vd	index of virtual domain. 0 matches all

11. Start debugging:
```
diag debug app ike 255
diag debug enable
```
12. Have the remote end attempt a VPN connection.

    If the remote end attempts the connection they become the initiator. This situation makes it easier to debug VPN tunnels because then you have the remote information and all of your local information. by initiate the connection, you will not see the other end's information.
13. If possible go to the web-based manager on your FortiGate unit, go to the VPN monitor and try to bring the tunnel up.
14. Stop the debug output:
```
diag debug disable
```

15. Go back through the output to determine what proposal information the initiator is using, and how it is different from your VPN P1 proposal settings.

Things to look for in the debug output of attempted VPN connections are shown below.

Important terms to look for in VPN debug output

`initiator`	Starts the VPN attempt, in the above procedure that is the remote end
`responder`	Answers the initiator's request
`local ID`	In aggressive mode, this is not encrypted
`error no SA proposal chosen`	There was no proposal match — there was no encryption-authentication pair in common, usually occurs after a long list of proposal attempts
`R U THERE and R U THERE ack`	dead peer detection (dpd), also known as dead gateway detection — after three failed attempts to contact the remote end it will be declared dead, no farther attempts will be made to contact it
`negotiation result`	lists the proposal settings that were agreed on
`SA_life_soft and SA_life_hard`	negotiating a new key, and the key life
`R U THERE`	If you see this, it means Phase 1 was successful
`tunnel up`	the negotiation was successful, the VPN tunnel is operational

Hub-and-spoke configurations

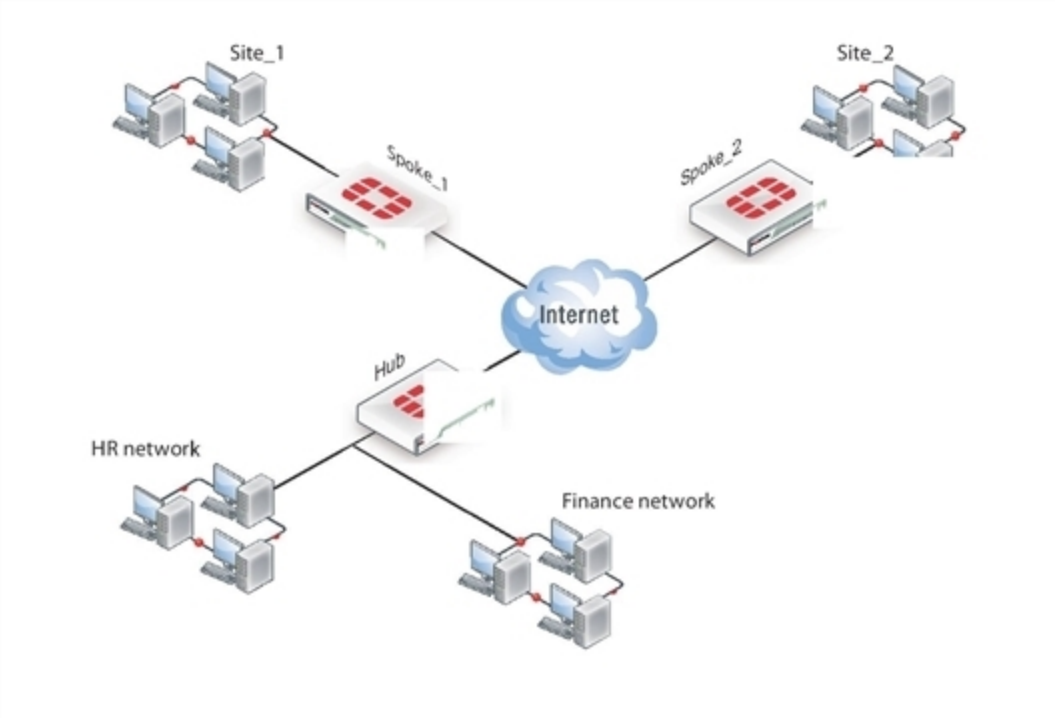
This section describes how to set up hub-and-spoke IPsec VPNs. The following topics are included in this section:

Configuration overview
Configure the hub
Configure the spokes
Dynamic spokes configuration example

Configuration overview

In a hub-and-spoke configuration, VPN connections radiate from a central FortiGate unit (the hub) to a number of remote peers (the spokes). Traffic can pass between private networks behind the hub and private networks behind the remote peers. Traffic can also pass between remote peer private networks through the hub.

Example hub-and-spoke configuration



The actual implementation varies in complexity depending on:

- Whether the spokes are statically or dynamically addressed
- The addressing scheme of the protected subnets
- How peers are authenticated

This guide discusses the issues involved in configuring a hub-and-spoke VPN and provides some basic configuration examples.

Hub-and-spoke infrastructure requirements

- The FortiGate hub must be operating in NAT mode and have a static public IP address.
- Spokes may have static IP addresses, dynamic IP addresses (see FortiGate dialup-client configurations on page 1669), or static domain names and dynamic IP addresses (see Dynamic DNS configuration on page 1639).

Spoke gateway addressing

The public IP address of the spoke is the VPN remote gateway as seen from the hub. Statically addressed spokes each require a separate VPN Phase 1 configuration on the hub. When there are many spokes, this becomes rather cumbersome.

Using dynamic addressing for spokes simplifies the VPN configuration because then the hub requires only a single Phase 1 configuration with “dialup user” as the remote gateway. You can use this configuration even if the remote peers have static IP addresses. A remote peer can establish a VPN connection regardless of its IP address if its traffic selectors match and it can authenticate to the hub. See Configuration overview on page 1623 for an example of this configuration.

Protected networks addressing

The addresses of the protected networks are needed to configure destination selectors and sometimes for security policies and static routes. The larger the number of spokes, the more addresses there are to manage. You can

- Assign spoke subnets as part of a larger subnet, usually on a new network

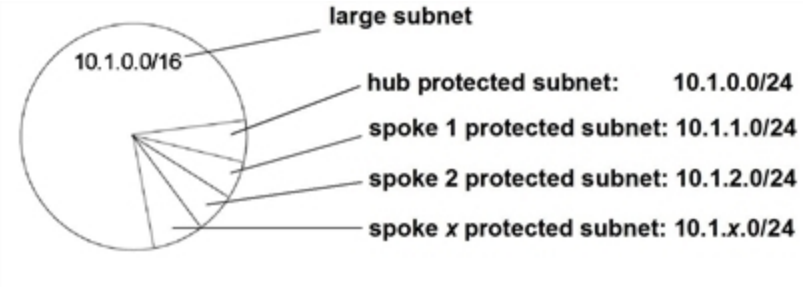
  or

- Create address groups that contain all of the needed addresses

Using aggregated subnets

If you are creating a new network, where subnet IP addresses are not already assigned, you can simplify the VPN configuration by assigning spoke subnets that are part of a large subnet.

Aggregated subnets



All spokes use the large subnet address, 10.1.0.0/16 for example, as:

- The IPsec destination selector
- The destination of the security policy from the private subnet to the VPN (required for policy-based VPN, optional for route-based VPN)
- The destination of the static route to the VPN (route-based)

Each spoke uses the address of its own protected subnet as the IPsec source selector and as the source address in its VPN security policy. The remote gateway is the public IP address of the hub FortiGate unit.

Using an address group

If you want to create a hub-and-spoke VPN between existing private networks, the subnet addressing usually does not fit the aggregated subnet model discussed earlier. All of the spokes and the hub will need to include the addresses of all the protected networks in their configuration.

On FortiGate units, you can define a named firewall address for each of the remote protected networks and add these addresses to a firewall address group. For a policy-based VPN, you can then use this address group as the destination of the VPN security policy.

For a route-based VPN, the destination of the VPN security policy can be set to All. You need to specify appropriate routes for each of the remote subnets.

Authentication

Authentication is by a common pre-shared key or by certificates. For simplicity, the examples in this chapter assume that all spokes use the same pre-shared key.

Configure the hub

At the FortiGate unit that acts as the hub, you need to:

- Configure the VPN to each spoke
- Configure communication between spokes

You configure communication between spokes differently for a policy-based VPN than for a route-based VPN. For a policy-based VPN, you configure a VPN concentrator. For a route-based VPN, you must either define security policies or group the IPsec interfaces into a zone

Define the hub-spoke VPNs

Perform these steps at the FortiGate unit that will act as the hub. Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

To configure the VPN hub

1. At the hub, define the Phase 1 configuration for each spoke. See Phase 1 parameters on page 1581. Enter these settings in particular:

Name	Enter a name to identify the VPN in Phase 2 configurations, security policies and the VPN monitor.

Remote Gateway	The remote gateway is the other end of the VPN tunnel. There are three options: **Static IP Address** — Enter the spoke's public **IP Address**. You will need to create a Phase 1 configuration for each spoke. Either the hub or the spoke can establish the VPN connection. **Dialup User** — No additional information is needed. The hub accepts connections from peers with appropriate encryption and authentication settings. Only one Phase 1 configuration is needed for multiple dialup spokes. Only the spoke can establish the VPN tunnel. **Dynamic DNS** — If the spoke subscribes to a dynamic DNS service, enter the spoke's **Dynamic DNS** domain name. Either the hub or the spoke can establish the VPN connection. For more information, see Dynamic DNS configuration on page 1639.
Local Interface	Select the FortiGate interface that connects to the remote gateway. This is usually the FortiGate unit's public interface.

2. Define the Phase 2 parameters needed to create a VPN tunnel with each spoke. See Phase 2 parameters on page 1598. Enter these settings in particular:

Name	Enter a name to identify this spoke Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined for this spoke.

Define the hub-spoke security policies

1. Define a name for the address of the private network behind the hub. For more information, see Defining VPN security policies on page 1603.
2. Define names for the addresses or address ranges of the private networks behind the spokes. For more information, see Defining VPN security policies on page 1603.
3. Define the VPN concentrator. See To define the VPN concentrator on page 1628.
4. Define security policies to permit communication between the hub and the spokes. For more information, see Defining VPN security policies on page 1603.

Route-based VPN security policies

Define ACCEPT security policies to permit communications between the hub and the spoke. You need one policy for each direction.

To add policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step 1.
Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
Outgoing Interface	Select the hub's interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 1.
Action	Select **ACCEPT**.
Enable NAT	Enable.

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured inStep 1.
Source Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate units.
Outgoing Interface	Select the source address that you defined in Step 1.
Destination Address	Select the hub's interface to the internal (private) network.
Action	Select **ACCEPT**.
Enable NAT	Enable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the hub and the spoke.

To add policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the hub's interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 1.
Outgoing Interface	Select the hub's public network interface.
Destination Address	Select the address name you defined in Step 2 for the private network behind the spoke FortiGate unit.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created for the spoke in Step 1. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

In the policy list, arrange the policies in the following order:

- IPsec policies that control traffic between the hub and the spokes first
- The default security policy last

Configuring communication between spokes (policy-based VPN)

For a policy-based hub-and-spoke VPN, you define a concentrator to enable communication between the spokes.

To define the VPN concentrator

1. At the hub, go to **VPN > IPsec > Concentrator** and select **Create New**.
2. In the **Concentrator Name** field, type a name to identify the concentrator.
3. From the **Available Tunnels** list, select a VPN tunnel and then select the right-pointing arrow.
4. Repeat Step 3 until all of the tunnels associated with the spokes are included in the concentrator.
5. Select **OK**.

Configuring communication between spokes (route-based VPN)

For a route-based hub-and-spoke VPN, there are several ways you can enable communication between the spokes:

- Put all of the IPsec interfaces into a zone and enable intra-zone traffic. This eliminates the need for any security policy for the VPN, but you cannot apply UTM features to scan the traffic for security threats.
- Put all of the IPsec interfaces into a zone and create a single zone-to-zone security policy
- Create a security policy for each pair of spokes that are allowed to communicate with each other. The number of policies required increases rapidly as the number of spokes increases.

Using a zone as a concentrator

A simple way to provide communication among all of the spokes is to create a zone and allow intra-zone communication. You cannot apply UTM features using this method.

1. Go to **System > Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Clear **Block intra-zone traffic**.
5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

Using a zone with a policy as a concentrator

If you put all of the hub IPsec interfaces involved in the VPN into a zone, you can enable communication among all of the spokes and apply UTM features with just one security policy.

To create a zone for the VPN

1. Go to **System > Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Select **Block intra-zone traffic**.

5. In the **Interface Members** list, select the IPsec interfaces that are part of your VPN.
6. Select **OK**.

To create a security policy for the zone

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the settings: and select **OK**.

Incoming Interface	Select the zone you created for your VPN.
Source Address	Select ***All***.
Outgoing Interface	Select the zone you created for your VPN.
Destination Address	Select ***All***.
Action	Select **ACCEPT**.
Enable NAT	Enable.

Using security policies as a concentrator

To enable communication between two spokes, you need to define an ACCEPT security policy for them. To allow either spoke to initiate communication, you must create a policy for each direction. This procedure describes a security policy for communication from Spoke 1 to Spoke 2. Others are similar.

1. Define names for the addresses or address ranges of the private networks behind each spoke. For more information, see Defining VPN security policies on page 1603.
2. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
3. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
4. Enter the settings and select **OK**.

Incoming Interface	Select the IPsec interface that connects to Spoke 1.
Source Address	Select the address of the private network behind Spoke 1.
Outgoing Interface	Select the IPsec interface that connects to Spoke 2.
Destination Address	Select the address of the private network behind Spoke 2.
Action	Select **ACCEPT**.
Enable NAT	Enable.

Configure the spokes

Although this procedure assumes that the spokes are all FortiGate units, a spoke could also be VPN client software, such as FortiClient Endpoint Security.

Perform these steps at each FortiGate unit that will act as a spoke.

To create the Phase 1 and phase_2 configurations

1. At the spoke, define the Phase 1 parameters that the spoke will use to establish a secure connection with the hub. See Phase 1 parameters on page 1581. Enter these settings:

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the interface that connects to the hub.

2. Create the Phase 2 tunnel definition. See Phase 2 parameters on page 1598. Select the set of Phase 1 parameters that you defined for the hub. You can select the name of the hub from the **Static IP Address** part of the list.

Configuring security policies for hub-to-spoke communication

1. Create an address for this spoke. See Defining VPN security policies on page 1603. Enter the IP address and netmask of the private network behind the spoke.
2. Create an address to represent the hub. See Defining VPN security policies on page 1603. Enter the IP address and netmask of the private network behind the hub.
3. Define the security policy to enable communication with the hub.

Route-based VPN security policy

Define two security policies to permit communications to and from the hub.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the hub address you defined in Step 1.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select the spoke addresses you defined in Step 2.
Action	Select **ACCEPT**.
Enable NAT	Enable

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the hub destination addresses you defined in Step 2.

Action	Select **ACCEPT**.
Enable NAT	Enable

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the hub. See Defining VPN security policies on page 1603.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select the spoke address you defined in Step 1.
Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the hub address you defined in Step 2.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration you defined. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

Configuring security policies for spoke-to-spoke communication

Each spoke requires security policies to enable communication with the other spokes. Instead of creating separate security policies for each spoke, you can create an address group that contains the addresses of the networks behind the other spokes. The security policy then applies to all of the spokes in the group.

1. Define destination addresses to represent the networks behind each of the other spokes. Add these addresses to an address group.
2. Define the security policy to enable communication between this spoke and the spokes in the address group you created.

Policy-based VPN security policy

Define an IPsec security policy to permit communications with the other spokes. See Defining VPN security policies on page 1603. Enter these settings in particular:

Route-based VPN security policy

Define two security policies to permit communications to and from the other spokes.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the virtual IPsec interface you created.
Source Address	Select the spoke address group you defined in Step "Configure the spokes " on page 1629.
Outgoing Interface	Select the spoke's interface to the internal (private) network.
Destination Address	Select this spoke's address name.
Action	Select **ACCEPT**.
Enable NAT	Enable

4. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select the spoke's interface to the internal (private) network.
Source Address	Select this spoke's address name.
Outgoing Interface	Select the virtual IPsec interface you created.
Destination Address	Select the spoke address group you defined in Step 1.
Action	Select **ACCEPT**.
Enable NAT	Enable

Policy-based VPN security policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following:

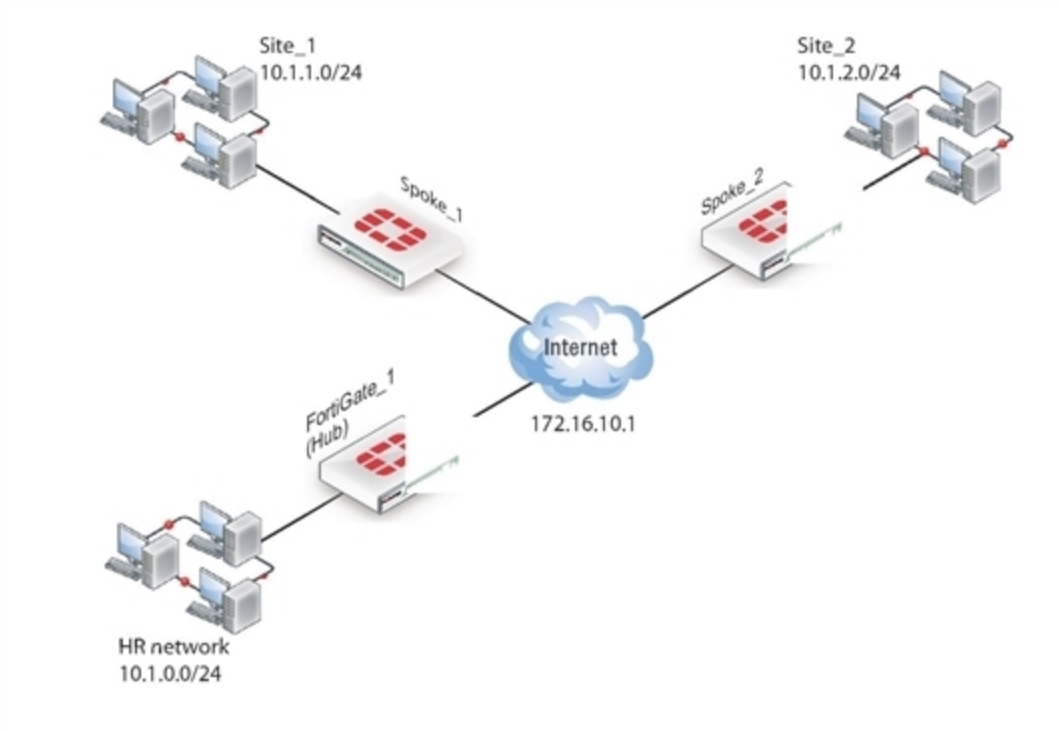
Incoming Interface	Select this spoke's internal (private) network interface.
Source Address	Select this spoke's source address.
Outgoing Interface	Select the spoke's interface to the external (public) network.
Destination Address	Select the spoke address group you defined in Step 1.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration you defined. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

Place this policy or policies in the policy list above any other policies having similar source and destination addresses.

Dynamic spokes configuration example

This example demonstrates how to set up a basic route-based hub-and-spoke IPsec VPN that uses preshared keys to authenticate VPN peers.

Example hub-and-spoke configuration



In the example configuration, the protected networks 10.1.0.0/24, 10.1.1.0/24 and 10.1.2.0/24 are all part of the larger subnet 10.1.0.0/16. The steps for setting up the example hub-and-spoke configuration create a VPN among Site 1, Site 2, and the HR Network.

The spokes are dialup. Their addresses are not part of the configuration on the hub, so only one spoke definition is required no matter the number of spokes. For simplicity, only two spokes are shown.

Configure the hub (FortiGate_1)

The Phase 1 configuration defines the parameters that FortiGate_1 will use to authenticate spokes and establish secure connections.

For the purposes of this example, one preshared key will be used to authenticate all of the spokes. Each key must contain at least 6 printable characters and best practices dictates that it only be known by network administrators. For optimum protection against currently known attacks, each key must consist of a minimum of 16 randomly chosen alphanumeric characters.

Define the IPsec configuration

To define the Phase 1 parameters

1. At FortiGate_1, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Define the Phase 1 parameters that the hub will use to establish a secure connection to the spokes.

Name	Enter a name (for example, `toSpokes`).
Remote Gateway	Dialup user
Local Interface	External
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID

The basic Phase 2 settings associate IPsec Phase 2 parameters with the Phase 1 configuration and specify the remote end points of the VPN tunnels.

To define the Phase 2 parameters

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter the following information, and select **OK**:

Name	Enter a name for the Phase 2 definition (for example, `toSpokes_ph2`).
Phase 1	Select the Phase 1 configuration that you defined previously (for example, `toSpokes`).

Define the security policies

security policies control all IP traffic passing between a source address and a destination address. For a route-based VPN, the policies are simpler than for a policy-based VPN. Instead of an IPSEC policy, you use an ACCEPT policy with the virtual IPsec interface as the external interface.

Before you define security policies, you must first define firewall addresses to use in those policies. You need addresses for:

- The HR network behind FortiGate_1
- The aggregate subnet address for the protected networks

To define the IP address of the HR network behind FortiGate_1

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	Enter an address name (for example, `HR_Network`).
Type	Subnet
Subnet/IP Range	Enter the IP address of the HR network behind FortiGate_1 (for example, `10.1.0.0/24`).

To specify the IP address the aggregate protected subnet

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Address Name	Enter an address name (for example, `Spoke_net`).
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, `10.1.0.0/16`

To define the security policy for traffic from the hub to the spokes

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**,
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the HR network, **port 1**.
Source Address	`Select` **HR_Network**.
Outgoing Interface	Select the virtual IPsec interface that connects to the spokes, `toSpokes`.
Destination Address	`Select` **Spoke_net**.
Action	Select **ACCEPT**.

Place the policy in the policy list above any other policies having similar source and destination addresses.

Configure communication between spokes

Spokes communicate with each other through the hub. You need to configure the hub to allow this communication. An easy way to do this is to create a zone containing the virtual IPsec interfaces even if there is only one, and create a zone-to-zone security policy.

To create a zone for the VPN

1. Go to **System > Network > Interfaces**.
2. Select the down-arrow on the **Create New** button and select **Zone**.
3. In the **Zone Name** field, enter a name, such as `Our_VPN_zone`.
4. Select **Block intra-zone traffic**.
   You could enable intra-zone traffic and then you would not need to create a security policy. But, you would not be able to apply UTM features.

5. In **Interface Members**, select the virtual IPsec interface, `toSpokes`.
6. Select **OK**.

To create a security policy for the zone

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings:

Incoming Interface	Select `Our_VPN_zone`.
Source Address	Select **All**.
Outgoing Interface	Select `Our_VPN_zone`.
Destination Address	Select **All**.
Action	Select **ACCEPT**.
Enable NAT	Enable.

4. Select **OK**.

Configure the spokes

In this example, all spokes have nearly identical configuration, requiring the following:

- Phase 1 authentication parameters to initiate a connection with the hub.
- Phase 2 tunnel creation parameters to establish a VPN tunnel with the hub.
- A source address that represents the network behind the spoke. This is the only part of the configuration that is different for each spoke.
- A destination address that represents the aggregate protected network.
- A security policy to ena.ble communications between the spoke and the aggregate protected network

Define the IPsec configuration

At each spoke, create the following configuration.

To define the Phase 1 parameters

1. At the spoke, go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button). Enter the following information:

Name	Type a name, for example, `toHub`.
Remote Gateway	Select **Static IP Address**.
IP Address	Enter `172.16.10.1`.

Local Interface	Select **Port2**.
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key. The value must be identical to the preshared key that you specified previously in the FortiGate_1 configuration
Peer Options	Select **Any peer ID**.

To define the Phase 2 parameters

1. Open the **Phase 2 Selectors** panel (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
2. Enter the following information and select **OK**:

Name	Enter a name for the tunnel, for example, `toHub_ph2`.
Phase 1	Select the name of the Phase 1 configuration that you defined previously, for example, `toHub`.
Advanced	Select to show the following **Quick Mode Selector** settings.
Source	Enter the address of the protected network at this spoke. For spoke_1, this is `10.1.1.0/24`. For spoke_2, this is `10.1.2.0/24`.
Destination	Enter the aggregate protected subnet address, `10.1.0.0/16`.

Define the security policies

You need to define firewall addresses for the spokes and the aggregate protected network and then create a security policy to enable communication between them.

To define the IP address of the network behind the spoke

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example `LocalNet`.
Type	Subnet
Subnet/IP Range	Enter the IP address of the private network behind the spoke. For spoke_1, this is `10.1.1.0/24`. For spoke_2, this is `10.1.2.0/24`.

To specify the IP address of the aggregate protected network

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New** and enter the following information:

Address Name	Enter an address name, for example, `Spoke_net`.
Type	Subnet
Subnet/IP Range	Enter the IP address of the aggregate protected network, `10.1.0.0/16`.

To define the security policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information:

Incoming Interface	Select the virtual IPsec interface, `toHub`.
Source Address	Select the aggregate protected network address `Spoke_net`.
Outgoing Interface	Select the interface to the internal (private) network, `port1`.
Destination Address	Select the address for this spoke's protected network `LocalNet`.
Action	Select **ACCEPT**.

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**:

Incoming Interface	Select the interface to the internal private network, `port1`.
Source Address	Select the address for this spoke's protected network, `LocalNet`.
Outgoing Interface	Select the virtual IPsec interface, `toHub`.
Destination Address	Select the aggregate protected network address, `Spoke_net`.
Action	Select **ACCEPT**.

Place these policies in the policy list above any other policies having similar source and destination addresses.

Dynamic DNS configuration

This section describes how to configure a site-to-site VPN, in which one FortiGate unit has a static IP address and the other FortiGate unit has a domain name and a dynamic IP address.

The following topics are included in this section:

Dynamic DNS over VPN concepts
Dynamic DNS topology
General configuration steps
Configure the dynamically-addressed VPN peer
Configure the fixed-address VPN peer
Testing

Dynamic DNS over VPN concepts

A typical computer has a static IP address and one or more DNS servers to resolve fully qualified domain names (FQDN) into IP addresses. A domain name assigned to this computer is resolved by any DNS server having an entry for the domain name and its static IP address. The IP address never changes or changes only rarely so the DNS server can reliably say it has the correct address for that domain all the time.

Dynamic DNS (DDNS)

It is different when a computer has a dynamic IP address, such as an IP address assigned dynamically by a DHCP server, and a domain name. Computers that want to contact this computer do not know what its current IP address is. To solve this problem there are dynamic DNS servers. These are public servers that store a DNS entry for your computer that includes its current IP address and associated domain name. These entries are kept up to date by your computer sending its current IP address to the dynamic DNS (DDNS) server to ensure its entry is always up to date. When other computers want to contact your domain, their DNS gets your IP address from your DDNS server. To use DDNS servers, you must subscribe to them and usually pay for their services.

When configuring DDNS on your FortiGate unit, go to **System > Network > DNS** and enable **Enable FortiGuard DDNS**. Then select the interface with the dynamic connection, which DDNS server you have an account with, your domain name, and account information. If your DDNS server is not on the list, there is a generic option where you can provide your DDNS server information.

Routing

When an interface has some form of changing IP address (DDNS, PPPoE, or DHCP assigned address), routing needs special attention. The standard static route cannot handle the changing IP address. The solution is to use the dynamic-gateway command in the CLI. Say for example you already have four static routes, and you have a PPPoE connection over the wan2 interface and you want to use that as your default route.

The route is configured on the dynamic address VPN peer trying to access the static address FortiGate unit.

To configure dynamic gateway routing - CLI

```
config router static
   edit 5
      set dst 0.0.0.0 0.0.0.0
```

```
        set dynamic-gateway enable
        set device wan2
    next
end
```

For more information on DDNS, see the System Administration handbook chapter.

Dynamic DNS over VPN

IPsec VPN expects an IP address for each end of the VPN tunnel. All configuration and communication with that tunnel depends on the IP addresses as reference points. However, when the interface the tunnel is on has DDNS enabled there is no set IP address. The remote end of the VPN tunnel now needs another way to reference your end of the VPN tunnel. This is accomplished using Local ID.

A FortiGate unit that has a domain name and a dynamic IP address can initiate VPN connections anytime. The remote peer can reply to the local FortiGate unit using the source IP address that was sent in the packet header because it is current. Without doing a DNS lookup first, the remote peer runs the risk of the dynamic IP changing before it attempts to connect. To avoid this, the remote peer must perform a DNS lookup for the domain name of to be sure of the dynamic IP address before initiating the connection.

Remote Gateway

When configuring the Phase 1 entry for a VPN tunnel, the Remote Gateway determines the addressing method the remote end of the tunnel uses as one of Static IP Address, Dialup User, or Dynamic DNS. There are different fields for each option.

When you select the Dynamic DNS VPN type there is a related field called Dynamic DNS. The Dynamic DNS field is asking for the FQDN of the remote end of the tunnel. It uses this information to look up the IP address of the remote end of the tunnel through the DDNS server associated with that domain name.

Local ID (peer ID)

The Local ID or peer ID can be used to uniquely identify one end of a VPN tunnel. This enables a more secure connection. Also if you have multiple VPN tunnels negotiating, this ensures the proper remote and local ends connect. When you configure it on your end, it is your Local ID. When the remote end connects to you, they see it as your peer ID.

If you are debugging a VPN connection, the Local ID is part of the VPN negotiations. You can use it to help troubleshoot connection problems.

To configure your Local ID

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Advanced**.
4. In the **Phase 1 Proposal** section, enter your Local ID.
5. Select **OK**.

The default configuration is to accept all local IDs (peer IDs). If you have the Local ID set, the remote end of the tunnel must be configured to accept your Local ID.

To accept a specific Peer ID

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Select **Aggressive** mode.
4. For **Peer Options**, select **This peer ID**. This option becomes visible only when Aggressive mode is selected.
5. Enter the string the other end of the tunnel used for its Local ID.
6. Configure the rest of the Phase 1 entry as required.
7. Select **OK**.

Route-based or policy-based VPN

VPN over dynamic DNS can be configured with either route-based or policy-based VPN settings. Both are valid, but have differences in configuration. Choose the best method based on your requirements. For more information on route-based and policy-based, see IPsec VPN overview on page 1563.

Route-based VPN configuration requires two security policies to be configured (one for each direction of traffic) to permit traffic over the VPN virtual interface, and you must also add a static route entry for that VPN interface or the VPN traffic will not reach its destination. See Dynamic DNS over VPN concepts on page 1639 and Dynamic DNS over VPN concepts on page 1639.

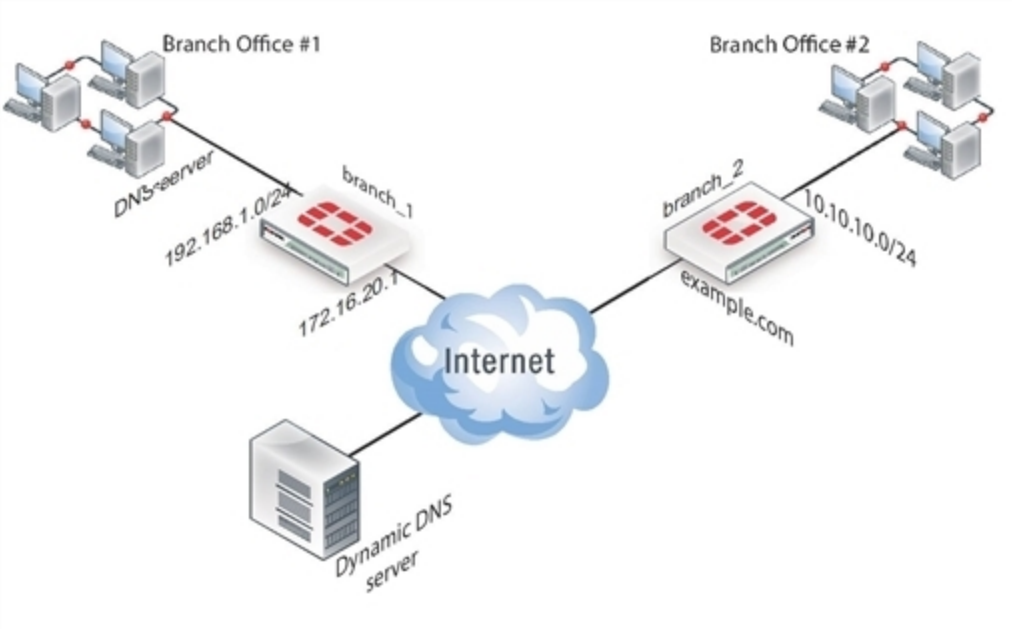
Policy-based VPN configuration uses more complex and often more IPsec security policies, but does not require a static route entry. It has the benefit of being able to configure multiple policies for handling multiple protocols in different ways, such as more scanning of less secure protocols or guaranteeing a minimum bandwidth for protocols such as VoIP. See Dynamic DNS over VPN concepts on page 1639 and Dynamic DNS over VPN concepts on page 1639.

Dynamic DNS topology

In this scenario, two branch offices each have a FortiGate unit and are connected in a gateway-to-gateway VPN configuration. One FortiGate unit has a domain name (example.com) with a dynamic IP address. See `branch_2` in the figure below.

Whenever the `branch_2` unit connects to the Internet (and possibly also at predefined intervals set by the ISP), the ISP may assign a different IP address to the FortiGate unit. The unit has its domain name registered with a dynamic DNS service. The `branch_2` unit checks in with the DDNS server on a regular basis, and that server provides the DNS information for the domain name, updating the IP address from time to time. Remote peers have to locate the `branch_2` FortiGate unit through a DNS lookup each time to ensure the address they get is current and correct.

Example dynamic DNS configuration



When a remote peer (such as the `branch_1` FortiGate unit above) initiates a connection to `example.com`, the local DNS server looks up and returns the IP address that matches the domain name `example.com`. The remote peer uses the retrieved IP address to establish a VPN connection with the `branch_2` FortiGate unit.

Assumptions

- You have administrator access to both FortiGate units.
- Both FortiGate units have interfaces named wan1 and internal. (If not, you can use the alias feature to assign these labels as “nicknames” to other interfaces to follow this example.)
- Both FortiGate units have the most recent firmware installed, have been configured for their networks, and are currently passing normal network traffic.
- The `branch_2` FortiGate unit has its `wan1` interface defined as a dynamic DNS interface with the domain name of **example.com**.
- A basic gateway-to-gateway configuration is in place (see Gateway-to-gateway configurations on page 1609) except one of the FortiGate units has a static domain name and a dynamic IP address instead of a static IP address.
- The FortiGate unit with the domain name is subscribed to one of the supported dynamic DNS services. Contact one of the services to set up an account. For more information and instructions about how to configure the FortiGate unit to push its dynamic IP address to a dynamic DNS server, see the System Administration handbook chapter.

General configuration steps

When a FortiGate unit receives a connection request from a remote VPN peer, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate the VPN peer. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

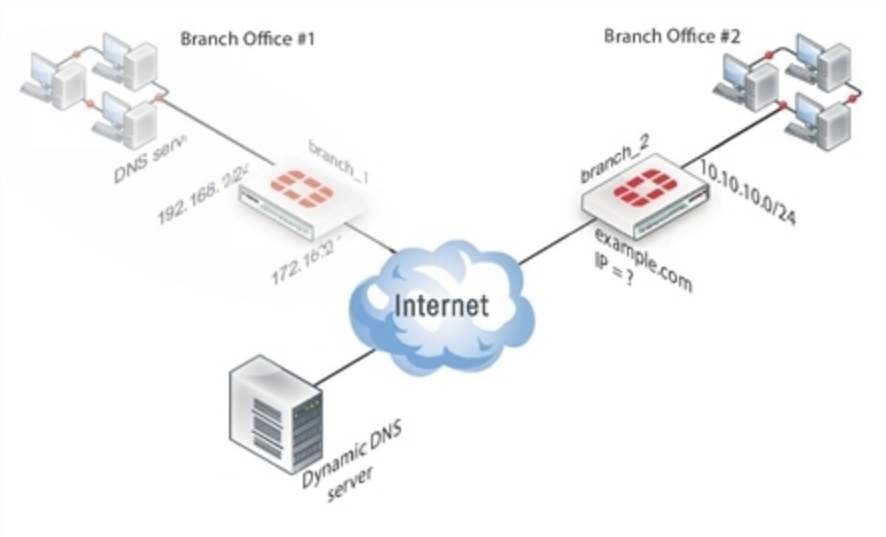
To support these functions, the following general configuration steps must be performed:

- Configure the branch_2 FortiGate unit with the dynamic IP address. This unit uses a Local ID string instead of an IP address to identify itself to the remote peer. See General configuration steps below.
  - General configuration steps
  - General configuration steps
- Configure the fixed-address VPN peer. To initiate a VPN tunnel with the dynamically-addressed peer, this unit must first retrieve the IP address for the domain from the dynamic DNS service. See General configuration steps on page 1643.
  - General configuration steps
  - General configuration steps

Configure the dynamically-addressed VPN peer

It is assumed that this FortiGate unit (`branch_2`) has already had its public facing interface, for example the `wan1`, configured with the proper dynamic DNS configuration.

Configure branch_2, the dynamic address side



Configuring the dynamically-addressed VPN peer includes:

- Configuring branch_2 VPN tunnel settings
- Configuring branch_2 security policies

Configuring branch_2 VPN tunnel settings

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. See Phase 1 parameters on page 1581. During this procedure you need to choose if you will be using route-based or policy-based VPNs.

To configure branch_2 VPN tunnel settings

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information:

Name	Enter `branch_2`, a name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies, and the VPN monitor.
Remote Gateway	Select **Static IP Address**. The remote peer this FortiGate is connecting to has a static IP public address. If the remote interface is PPPoE do not select **Retrieve default gateway from server**.
IP Address	Enter `172.16.20.1`. The IP address of the public interface to the remote peer.

Enter 172.16.20.1 The IP address of the public interface to the remote peer.	Select **Aggressive**.

4. Select **Advanced** and complete the following:

Local ID	Enter `example.com`. A character string used by the `branch_2` FortiGate unit to identify itself to the remote peer. This value must be identical to the value in the **This peer ID** field of the Phase 1 remote gateway configuration on the branch_1 remote peer. See Configure the dynamically-addressed VPN peer on page 1643.

5. Open the **Phase 2 Selectors** panel.

   Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For details on Phase 2, see Phase 2 parameters on page 1598.
6. Enter the following information and select **OK**.

Name	Enter `branch_2_phase2`. A name to identify this Phase 2 configuration.
Phase 1	Select `branch_2`. The name of the Phase 1 configuration that you defined earlier.

Configuring branch_2 security policies

Define security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1603.

After defining the two address ranges, select one of Creating branch_2 route-based security policies on page 1646 or Creating branch_2 policy-based security policies on page 1648 to configure the appropriate VPN policies.

Define address ranges for branch_2 security policies

Define VPN connection names for the address ranges of the private networks. These addresses are used in the security policies that permit communication between the networks. For more information, see Defining VPN security policies on page 1603.

Define an address name for the IP address and netmask of the private network behind the local FortiGate unit.

To define branch_2 address ranges

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**.

3. Enter the following information, and select **OK**.

Name	Enter `branch_2_internal`. Enter a meaningful name.
Type	Select **Subnet**.
Subnet / IP Range	Enter `10.10.10.0/24`. Include the netmask or specify a specific range.
Interface	Select **internal**. The interface that will be handling the traffic from the internal network.

Define an address name for the IP address and netmask of the private network behind the remote peer.

4. Select **Create New**.
5. Enter the following information, and select **OK**.

Name	Enter `branch_1_internal`. A meaningful name for the private network at the remote end of the VPN tunnel.
Type	Select **Subnet**.
Subnet / IP Range	Enter `192.168.1.0/24`. Include the netmask. Optionally you can specify a range
Interface	Select **any**. The interface that will be handling the remote VPN traffic on this FortiGate unit. If you are unsure, or multiple interfaces may be handling this traffic use `any`.

Creating branch_2 route-based security policies

Define ACCEPT security policies to permit communication between the branch_2 and branch_1 private networks. Once the route-based policy is configured a routing entry must be configured to route traffic over the VPN interface.

Define a policy to permit the branch_2 local FortiGate unit to initiate a VPN session with the branch_1 VPN peer.

To create route-based security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**.

Incoming Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Source Address	Select **branch_2_internal**. Select the address name for the private network behind this FortiGate unit.
Outgoing Interface	Select **branch_2**. The VPN Tunnel (IPsec Interface).
Destination Address	Select **branch_1_internal**. The address name the private network behind the remote peer.
Action	Select ***ACCEPT***.
Enable NAT	Disable.
Comments	Route-based: Initiate a branch_2 to branch_1 VPN tunnel.

Define a policy to permit the branch_1 remote VPN peer to initiate VPN sessions.

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**.

Incoming Interface	Select **branch_2**. The VPN Tunnel (IPsec Interface).
Source Address	Select **branch_1_internal**. The address name for the private network behind the remote peer.
Outgoing Interface	Select **internal**. The interface connecting the private network behind this FortiGate unit.
Destination Address	Select **branch_2_internal**. The address name for the private network behind this FortiGate unit.
Action	Select ***ACCEPT***.
Enable NAT	Disable.
Comments	Route-based: Initiate a branch_1 to branch_2 internal VPN tunnel.

7. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
8. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

To create routing entry for VPN interface - CLI

```
config router static
   edit 5
      set dst 0.0.0.0 0.0.0.0
      set dynamic-dateway enable
```

```
        set device wan1
    next
end
```

This routing entry must be added in the CLI because the dynamic-gateway option is not available in the web-based manager.

Creating branch_2 policy-based security policies

Define an IPsec policy to permit VPN sessions between the private networks. Define an IPsec policy to permit the VPN sessions between the local branch_2 unit and the remote branch_1 unit.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**.

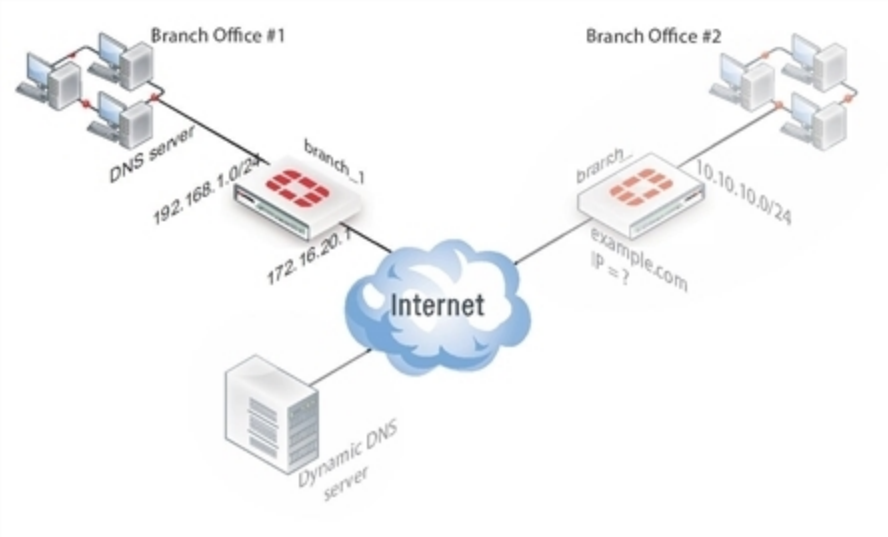
Incoming Interface	Select **internal**. The interface connecting the private network behind this FortiGate unit.
Source Address	Select **branch_2_internal**. The address name for the private network behind this local FortiGate unit.
Outgoing Interface	Select **wan1**. The FortiGate unit's public interface.
Destination Address	Select **branch_1_internal**. The address name for the private network behind branch_1, the remote peer.
VPN Tunnel	Select **Use Existing** and select **branch_2** from the drop-down list. The name of the Phase 1 tunnel.
	Select **Allow traffic to be initiated from the remote site**.
Comments	Policy-based: allows traffic in either direction to initiate the VPN tunnel.

3. Optionally configure any other security policy settings you require such as UTM or traffic shaping for this policy.
4. Place these policies in the policy list above any other policies having similar source and destination addresses. This will ensure VPN traffic is matched against the VPN policies before any other policies.

Configure the fixed-address VPN peer

The fixed-address VPN peer, branch_1, needs to retrieve the IP address from the dynamic DNS service to initiate communication with the dynamically-addressed peer, branch_2. It also depends on the peer ID (local ID) to initiate the VPN tunnel with branch_2.

Configure branch_1, the fixed address side



Configuring the fixed-address VPN peer includes:

- Configuring branch_1 VPN tunnel settings
- Configuring branch_1 security policies

Configuring branch_1 VPN tunnel settings

Define the Phase 1 parameters needed to establish a secure connection with the remote peer. For more information, see Phase 1 parameters on page 1581.

To configure branch_1 Phase 1 VPN settings

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information and select **OK**.

Name	Enter `branch_1`. A name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select **Dynamic DNS**. The remote peer this FortiGate is connecting to has a dynamic IP address.
Dynamic DNS	Type the fully qualified domain name of the remote peer (for example, `example.com`).
Interface	Select **wan1**. The public facing interface on the fixed-address FortiGate unit.
Mode	Select **Aggressive**.
Peer Options	Select **This peer ID**, and enter `example.com`. This option only appears when the mode is set to Aggressive. The identifier of the FortiGate unit with the dynamic address.

4. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See Phase 2 parameters on page 1598. Enter these settings in particular:

Name	Enter `branch_1_p2`. A name to identify this Phase 2 configuration.
Phase 1	Select **branch_1**. The name of the Phase 1 configuration that you defined for the remote peer. You can select the name of the remote gateway from the Dynamic DNS part of the list.

Configuring branch_1 security policies

The `branch_1` FortiGate unit has a fixed IP address and will be connecting to the `branch_2` FortiGate unit that has a dynamic IP address and a domain name of `example.com`. Remember if you are using route-based security policies that you must add a route for the VPN traffic.

Defining address ranges for branch_1 security policies

As with `branch_2` previously, `branch_1` needs address ranges defined as well. See Defining VPN security policies on page 1603.

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**.
3. Enter the following information, and select **OK**.

Name	Enter `branch_2_internal`. A meaningful name for the private network behind the `branch_2` FortiGate unit.
Type	Select **Subnet**.
Subnet / IP Range	Enter `10.10.10.0/24`. Include the netmask or specify a specific range.
Interface	Select **internal**. This is the interface on this FortiGate unit that will be handling with this traffic.

4. Define an address name for the IP address and netmask of the private network behind the remote peer.
5. Select **Create New**.
6. Enter the following information, and select **OK**.

Name	Enter `branch_1_internal`. A meaningful name for the private network behind the `branch_1` peer.
Type	Select **Subnet**.
Subnet / IP Range	Enter `192.168.1.0/24`. Include the netmask or specify a specific range.
Interface	Select **any**. The interface on this FortiGate unit that will be handling with this traffic. If you are unsure, or multiple interfaces may be handling this traffic use `any`.

Creating branch_1 route-based security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses. See Defining VPN security policies on page 1603.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**.

Incoming Interface	Select **internal**. The interface that connects to the private network behind the `branch_1` FortiGate unit.
Source Address	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Outgoing Interface	Select **branch_1**. The VPN Tunnel (IPsec Interface) you configured earlier.
Destination Address	Select **branch_2_internal**. The address name that you defined for the private network behind the `branch_2` peer.
Action	Select **ACCEPT**.
Enable NAT	Disable
Comments	Internal -> branch2

To permit the remote client to initiate communication, you need to define a security policy for communication in that direction.

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**.

Incoming Interface	Select **branch_1**. The VPN Tunnel (IPsec Interface) you configured earlier.
Source Address	Select **branch_2_internal**. The address name that you defined for the private network behind the `branch_2` remote peer.
Outgoing Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Destination Address	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Action	Select **ACCEPT**.
Enable NAT	Disable
Comments	branch_2 -> Internal

Creating branch_1 policy-based security policies

A policy-based security policy allows you the flexibility to allow inbound or outbound traffic or both through this single policy.

This policy-based IPsec VPN security policy allows both inbound and outbound traffic

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**.

Incoming Interface	Select **internal**. The interface that connects to the private network behind this FortiGate unit.
Source Address	Select **branch_1_internal**. The address name that you defined for the private network behind this FortiGate unit.
Outgoing Interface	Select **wan1**. The FortiGate unit's public interface.
Destination Address	Select **branch_2_internal**. The address name that you defined for the private network behind the remote peer.
VPN Tunnel	Select **Use Existing** and select **branch_1** from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

3. Place this security policy in the policy list above any other policies having similar source and destination addresses.

Testing

Once both ends are configured, you can test the VPN tunnel.

To test the VPN initiated by branch_2

1. On branch_2, go to **VPN > Monitor > IPsec Monitor**.
   All IPsec VPN tunnels will be listed on this page, no matter if they are connected or disconnected.
2. Select the tunnel listed for branch_2, and select the status column for that entry.
   The status will say **Bring Up** and remote port, incoming and outgoing data will all be zero. This indicates an inactive tunnel. When you select **Bring Up**, the FortiGate will try to set up a VPN session over this tunnel. If it is successful, Bring Up will change to Active, and the arrow icon will change to a green up arrow icon.
3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting:

To test the VPN initiated by branch_1

1. On branch_1, go to **VPN > Monitor > IPsec Monitor**.
2. Select the tunnel listed for branch_1, and select the status column.
   The difference between branch_2 and branch_1 at this point is that the tunnel entry for branch-1 will not have a remote gateway IP address. It will be resolved when the VPN tunnel is started.

3. If this does not create a VPN tunnel with increasing values for incoming and outgoing data, you need to start troubleshooting.

Some troubleshooting ideas include:

- If there was no entry for the tunnel on the monitor page, check the Auto Key (IKE) page to verify the Phase 1 and Phase 2 entries exist.
- Check the security policy or policies, and ensure there is an outgoing policy as a minimum.
- Check that you entered a local ID in the Phase 1 configuration, and that branch_1 has the same local ID.
- Ensure the local DNS server has an up-to-date DNS entry for exmaple.com.

For more information on VPN troubleshooting and testing, see Logging and monitoring on page 1769.

FortiClient dialup-client configurations

The FortiClient Endpoint Security application is an IPsec VPN client with antivirus, antispam and firewall capabilities. This section explains how to configure dialup VPN connections between a FortiGate unit and one or more FortiClient Endpoint Security applications.

FortiClient users are usually mobile or remote users who need to connect to a private network behind a FortiGate unit. For example, the users might be employees who connect to the office network while traveling or from their homes.

For greatest ease of use, the FortiClient application can download the VPN settings from the FortiGate unit to configure itself automatically. This section covers both automatic and manual configuration.

The following topics are included in this section:

Configuration overview
FortiClient-to-FortiGate VPN configuration steps
Configure the FortiGate unit
Configure the FortiClient Endpoint Security application
Adding XAuth authentication
FortiClient dialup-client configuration example

Configuration overview

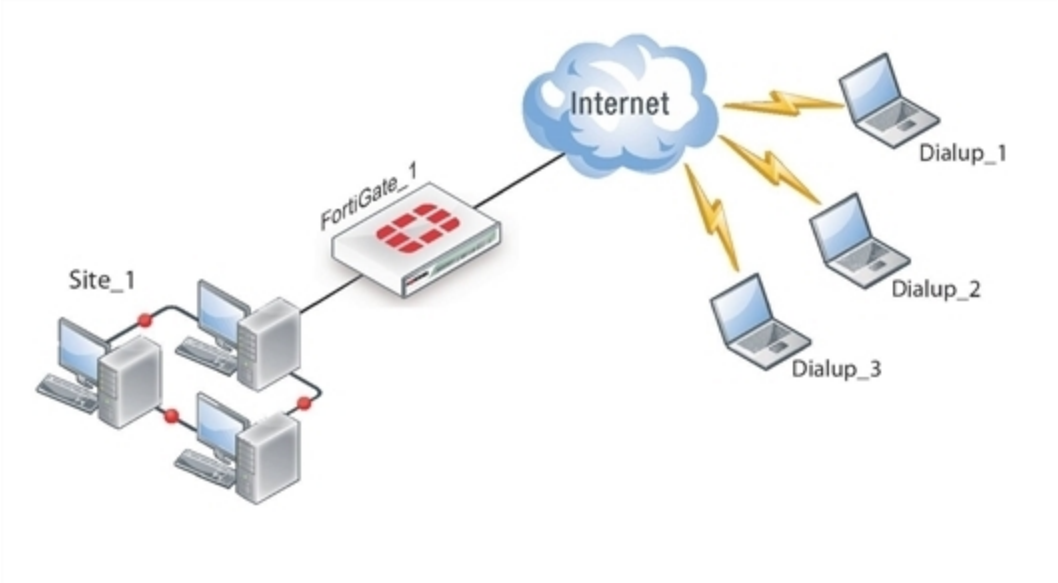
Dialup users typically obtain dynamic IP addresses from an ISP through Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE). Then, the FortiClient Endpoint Security application initiates a connection to a FortiGate dialup server.

By default the FortiClient dialup client has the same IP address as the host PC on which it runs. If the host connects directly to the Internet, this is a public IP address. If the host is behind a NAT device, such as a router, the IP address is a private IP address. The NAT device must be NAT traversal (NAT-T) compatible to pass encrypted packets (see Phase 1 parameters on page 1581). The FortiClient application also can be configured to use a virtual IP address (VIP). For the duration of the connection, the FortiClient application and the FortiGate unit both use the VIP address as the IP address of the FortiClient dialup client.

For a faster and easier method of configuring a FortiGate-to-FortiClient VPN, see One button FortiGate-to-FortiClient Phase 1 VPN on page 1656.

The FortiClient application sends its encrypted packets to the VPN remote gateway, which is usually the public interface of the FortiGate unit. It also uses this interface to download VPN settings from the FortiGate unit. See Automatic configuration of FortiClient dialup clients on page 1655.

Example FortiClient dialup-client configuration



Peer identification

The FortiClient application can establish an IPsec tunnel with a FortiGate unit configured to act as a dialup server. When the FortiGate unit acts as a dialup server, it does not identify the client using the Phase 1 remote gateway address. The IPsec tunnel is established if authentication is successful and the IPsec security policy associated with the tunnel permits access. If configured, the FortiGate unit could also require FortiClient registration, that is, the remote user would be required to have FortiClient installed before connection is completed.

There are several different ways to authenticate dialup clients and restrict access to private networks based on client credentials. For more information, see Phase 1 parameters on page 1581.

Automatic configuration of FortiClient dialup clients

The FortiClient application can obtain its VPN settings from the FortiGate VPN server. FortiClient users need to know only the FortiGate VPN server IP address and their user name and password on the FortiGate unit.

The FortiGate unit listens for VPN policy requests from clients on TCP port 8900. When the dialup client connects:

- The client initiates a Secure Sockets Layer (SSL) connection to the FortiGate unit.
- The FortiGate unit requests a user name and password from the FortiClient user. Using these credentials, it authenticates the client and determines which VPN policy applies to the client.
- Provided that authentication is successful, the FortiGate unit downloads a VPN policy to the client over the SSL connection. The information includes IPsec Phase 1 and Phase 2 settings, and the IP addresses of the private networks that the client is authorized to access.
- The client uses the VPN policy settings to establish an IPsec Phase 1 connection and Phase 2 tunnel with the FortiGate unit.

One button FortiGate-to-FortiClient Phase 1 VPN

On the FortiOS VPN IKE page there is a method to create a Phase 1 portion of a VPN tunnel between the FortiGate and FortiClient. Very little information is required for this configuration. No encryption or authentication method is required. This feature is ideal for setting up quick VPN connections with basic settings.

On the Phase 1 screen is the option **Create a FortiClient VPN.** When selected, the FortiGate uint requires a few basic VPN configuration related questions. Once all the information is added, select **OK**. This will create a new dial-up IPsec-interface mode tunnel. Phase 1 and Phase 2 will be added using the default IKE settings.

The following Settings will be used when creating a one-button FortiClient VPN Phase 1 object:

- Remote Gateway: Dialup User
- Mode: Aggressive
- Default setting for Phase 1 and 2 Proposals
- XAUTH Enable as Server (Auto)
- IKE mode-config will be enabled
- Peer Option set to “Any peer ID”
- Rest of the setting use the current defaults (Default value needs to be the same on FCT side)

Once the completed, you need tocreate a default Phase 2 configuration. This only requires a name for the Phase 2 object, and select the FortiClient connection Phase 1 name.

How the FortiGate unit determines which settings to apply

The FortiGate unit follows these steps to determine the configuration information to send to the FortiClient application:

1. Check the virtual domain associated with the connection to determine which VPN policies might apply.
2. Select the VPN policy that matches the dialup client’s user group and determine which tunnel (Phase 1 configuration) is involved.
3. Check all IPsec security policies that use the specified tunnel to determine which private networks the dialup clients may access.
4. Retrieve the rest of the VPN policy information from the existing IPsec Phase 1 and Phase 2 parameters in the dialup-client configuration.

Using virtual IP addresses

When the FortiClient host PC is located behind a NAT device, unintended IP address overlap issues may arise between the private networks at the two ends of the tunnel. For example, the client’s host might receive a private IP address from a DHCP server on its network that by co-incidence is the same as a private IP address on the network behind the FortiGate unit. A conflict will occur in the host’s routing table and the FortiClient Endpoint Security application will be unable to send traffic through the tunnel. Configuring virtual IP (VIP) addresses for FortiClient applications prevents this problem.

Using VIPs ensures that client IP addresses are in a predictable range. You can then define security policies that allow access only to that source address range. If you do not use VIPs, the security policies must allow all source addresses because you cannot predict the IP address for a remote mobile user.

The FortiClient application must not have the same IP address as any host on the private network behind the FortiGate unit or any other connected FortiClient application. You can ensure this by reserving a range of IP

addresses on the private network for FortiClient users. Or, you can assign FortiClient VIPs from an uncommonly used subnet such as 10.254.254.0/24 or 192.168.254.0/24.

You can reserve a VIP address for a particular client according to its device MAC address and type of connection. The DHCP server then always assigns the reserved VIP address to the client. For more information about this feature, see the “dhcp reserved-address” section in the “system” chapter of the FortiGate CLI Reference.

On the host computer, you can find out the VIP address that the FortiClient Endpoint Security application is using. For example, in Windows command prompt, type `ipconfig /all`

On Linux or Mac OS X, type `ifconfig` in a terminal window. The output will also show the IP address that has been assigned to the host Network Interface Card (NIC).

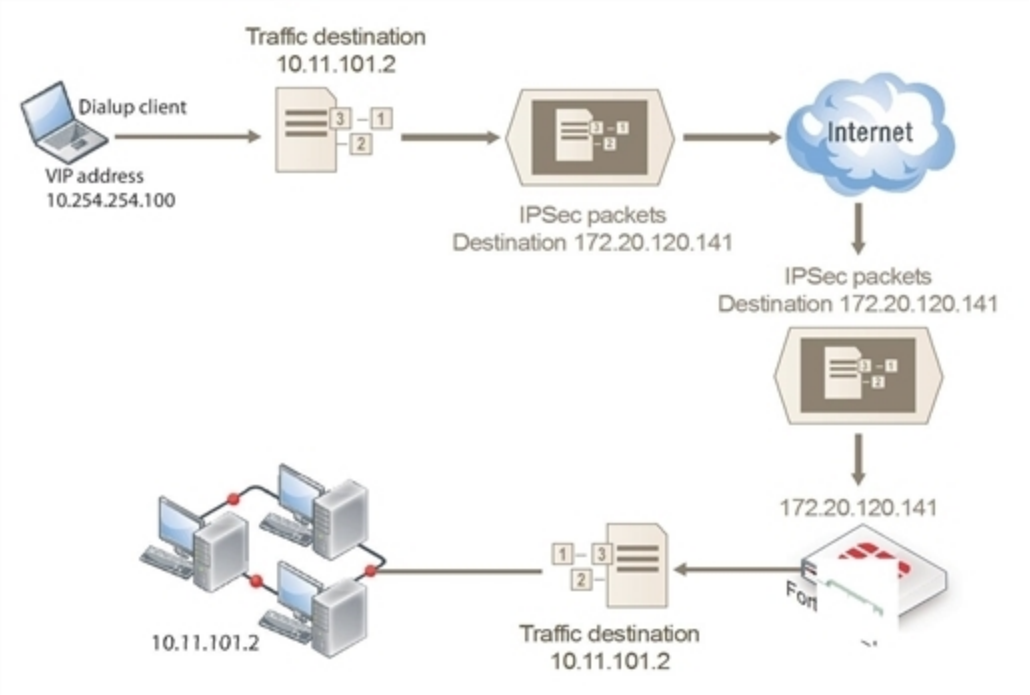
It is best to assign VIPs using DHCP over IPsec. The FortiGate dialup server can act as a DHCP server or relay requests to an external DHCP server. You can also configure VIPs manually on FortiClient applications, but it is more difficult to ensure that all clients use unique addresses.

If you assign a VIP on the private network behind the FortiGate unit and enable DHCP-IPsec (a Phase 2 advanced option), the FortiGate unit acts as a proxy on the local private network for the FortiClient dialup client. Whenever a host on the network behind the dialup server issues an ARP request for the device MAC address of the FortiClient host, the FortiGate unit answers the ARP request on behalf of the FortiClient host and forwards the associated traffic to the FortiClient host through the tunnel. For more information, see Phase 2 parameters on page 1598.

FortiGate units fully support RFC 3456. The FortiGate DHCP over IPsec feature can be enabled to allocate VIP addresses to FortiClient dialup clients using a FortiGate DHCP server.

The figure below shows an example of a FortiClient-to-FortiGate VPN where the FortiClient application is assigned a VIP on an uncommonly used subnet. The diagram also shows that while the destination for the information in the encrypted packets is the private network behind the FortiGate unit, the destination of the IPsec packets themselves is the public interface of the FortiGate unit that acts as the end of the VPN tunnel.

IP address assignments in a FortiClient dialup-client configuration



Assigning VIPs by RADIUS user group

If you use XAuth authentication, you can assign users the virtual IP address stored in the Framed-IP-Address field of their record on the RADIUS server. (See RFC 2865 and RFC 2866 for more information about RADIUS fields.) To do this:

- Set the DHCP server **IP Assignment Mode** to **User-group defined method**. This is an Advanced setting. See Configuration overview on page 1654.
- Create a new firewall user group and add the RADIUS server to it.
- In your Phase 1 settings, configure the FortiGate unit as an XAuth server and select from **User Group** the new user group that you created. For more information, see Phase 1 parameters on page 1581.
- Configure the FortiClient application to use XAuth. See Configuration overview on page 1654.

FortiClient dialup-client infrastructure requirements

- To support policy-based VPNs, the FortiGate dialup server may operate in either NAT mode or transparent mode. NAT mode is required if you want to create a route-based VPN.
- If the FortiClient dialup clients will be configured to obtain VIP addresses through FortiGate DHCP relay, a DHCP server must be available on the network behind the FortiGate unit and the DHCP server must have a direct route to the FortiGate unit.
- If the FortiGate interface to the private network is not the default gateway, the private network behind the FortiGate unit must be configured to route IP traffic destined for dialup clients back (through an appropriate gateway) to the FortiGate interface to the private network. As an alternative, you can configure the IPsec security policy on the FortiGate unit to perform inbound NAT on IP packets. Inbound NAT translates the source addresses of inbound decrypted packets into the IP address of the FortiGate interface to the local private network.

FortiClient-to-FortiGate VPN configuration steps

Configuring dialup client capability for FortiClient dialup clients involves the following general configuration steps:

1. If you will be using VIP addresses to identify dialup clients, determine which VIP addresses to use. As a precaution, consider using VIP addresses that are not commonly used.
2. Configure the FortiGate unit to act as a dialup server. See FortiClient-to-FortiGate VPN configuration steps on page 1659.
3. If the dialup clients will be configured to obtain VIP addresses through DHCP over IPsec, configure the FortiGate unit to act as a DHCP server or to relay DHCP requests to an external DHCP server.
4. Configure the dialup clients. See FortiClient-to-FortiGate VPN configuration steps on page 1659.

When a FortiGate unit has been configured to accept connections from FortiClient dialup-clients, you can optionally arrange to have an IPsec VPN configuration downloaded to FortiClient dialup clients automatically. For more information, see FortiClient-to-FortiGate VPN configuration steps on page 1659.

Configure the FortiGate unit

Configuring the FortiGate unit to establish VPN connections with FortiClient Endpoint Security users involves the following steps:

- Configure the VPN settings
- If the dialup clients use automatic configuration, configure the FortiGate unit as a VPN policy server
- If the dialup clients obtain VIP addresses by DHCP over IPsec, configure an IPsec DHCP server or relay

The procedures in this section cover basic setup of policy-based and route-based VPNs compatible with FortiClient Endpoint Security. A route-based VPN is simpler to configure.

Configuring FortiGate unit VPN settings

To configure FortiGate unit VPN settings to support FortiClient users, you need to:

- Configure the FortiGate Phase 1 VPN settings
- Configure the FortiGate Phase 2 VPN settings
- Add the security policy

1. On the local FortiGate unit, define the Phase 1 configuration needed to establish a secure connection with the FortiClient peer. See Phase 1 parameters on page 1581. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select **Dialup User**.
Local Interface	Select the interface through which clients connect to the FortiGate unit.
Mode	Select **Main (ID Protection)**.

Authentication Method	Select **Pre-shared Key**.
Pre-shared Key	Enter the pre-shared key. This must be the same preshared key provided to the FortiClient users.
Peer option	Select **Any peer ID**.

2. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiClient peer. See Phase 2 parameters on page 1598. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.
Advanced	Select to configure the following optional setting.
DHCP-IPsec	Select if you provide virtual IP addresses to clients using DHCP.

3. Define names for the addresses or address ranges of the private networks that the VPN links. These addresses are used in the security policies that permit communication between the networks. For more information, see Defining VPN security policies on page 1603.

   Enter these settings in particular:
   - Define an address name for the individual address or the subnet address that the dialup users access through the VPN.
   - If FortiClient users are assigned VIP addresses, define an address name for the subnet to which these VIPs belong.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1603.

If the security policy, which grants the VPN Connection is limited to certain services, DHCP must be included, otherwise the client won't be able to retrieve a lease from the FortiGate's (IPsec) DHCP server, because the DHCP Request (coming out of the tunnel) will be blocked.

Route-based VPN security policies

Define an ACCEPT security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the VPN Tunnel (IPsec Interface) you configured in Step "Configure the FortiGate unit" on page 1659.
Source Address	Select **All**.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.

Destination Address	Select **All**.
Action	Select **ACCEPT**.
Enable NAT	Disable.

If you want to allow hosts on the private network to initiate communications with the FortiClient users after the tunnel is established, you need to define a security policy for communication in that direction.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select **All**.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	Select **All**.
Action	Select **ACCEPT**.
Enable NAT	Disable.

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select the address name that you defined in Step "Configure the FortiGate unit" on page 1659 for the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	If FortiClient users are assigned VIPs, select the address name that you defined for the VIP subnet. Otherwise, select **All**.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created in Step "Configure the FortiGate unit" on page 1659. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

Place VPN policies in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiGate unit as a VPN policy server

When a FortiClient application set to automatic configuration connects to the FortiGate unit, the FortiGate unit requests a user name and password. If the user supplies valid credentials, the FortiGate unit downloads the VPN settings to the FortiClient application.

You must do the following to configure the FortiGate unit to work as a VPN policy server for FortiClient automatic configuration:

1. Create user accounts for FortiClient users.
2. Create a user group for FortiClient users and the user accounts that you created in step 1.
3. Connect to the FortiGate unit CLI and configure VPN policy distribution as follows:

```
config vpn ipsec forticlient
   edit <policy_name>
      set phase2name <tunnel_name>
      set usergroupname <group_name>
      set status enable
   end
```

`<tunnel_name>` must be the Name you specified in the step 2 of Configure the FortiGate unit on page 1659. `<group_name>` must be the name of the user group your created for FortiClient users.

Configuring DHCP services on a FortiGate interface

If the FortiClient dialup clients are configured to obtain a VIP address using DHCP, configure the FortiGate dialup server to either:

- Relay DHCP requests to a DHCP server behind the FortiGate unit (see To configure DHCP relay on a FortiGate interface on page 1662 below).
- Act as a DHCP server (see To configure a DHCP server on a FortiGate interface on page 1662).

Note that DHCP services are typically configured during the interface creation stage, but you can return to an interface to modify DHCP settings if need be.

To configure DHCP relay on a FortiGate interface

1. Go to **System > Network > Interfaces** and select the interface that you want to relay DHCP.
2. Under **DHCP Server**, select **Enable** and create a new DHCP **Address Range** and **Netmask**.
3. Open the **Advanced...** menu and select **Relay** for the **Mode** option.
4. For the **Type**, select **IPsec**.
5. Select **OK**.

To configure a DHCP server on a FortiGate interface

1. Go to **System > Network > Interfaces** and select the interface that you want to act as a DHCP server.
2. Under **DHCP Server**, select **Enable** and create a new DHCP **Address Range** and **Netmask**.
3. For **Default Gateway**, enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
4. For **DNS Server**, select **Same as System DNS**. If you want to use a different DNS server for VPN clients, select ***Specify*** and enter an IP address in the available field.
5. Open the **Advanced...** menu and select **Server** for the **Mode** option.
6. For the **Type**, select **IPsec**.
7. Select **OK**.

Configure the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to communicate with a remote FortiGate dialup server using the VIP address that you specify manually. These procedures are based on FortiClient 5.0.

Configuring FortiClient

This procedure explains how to configure the FortiClient application manually using the default IKE and IPsec settings. For more information, refer to the FortiClient Administration Guide.

This procedure includes instructions for configuring a virtual IP for the FortiClient application, either manually or using DHCP over IPsec.

To create a FortiClient VPN configuration

1. Go to **Remote Access** and select the down-arrow for the VPN connection.
2. Select **Add new connection** and complete following information:

VPN Type	Select **IPsec VPN**.
Connection Name	Enter a descriptive name for the connection.
Remote Gateway	Enter the IP address or the fully qualified domain name (FQDN) of the remote gateway.
Authentication Method	Select **Pre-shared Key**.
Pre-shared Key	Enter the pre-shared key.
User Name	Enter the user name to connect to the tunnel.

3. Select **OK**.

Adding XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit challenges the user for a user name and password. It then forwards the user's credentials to an external RADIUS or LDAP server for verification.

Implementation of XAuth requires configuration at both the FortiGate unit and the FortiClient application. For information about configuring a FortiGate unit as an XAuth server, see Phase 1 parameters on page 1581. The following procedure explains how to configure the FortiClient application.

Note that XAuth is not compatible with IKE version 2.

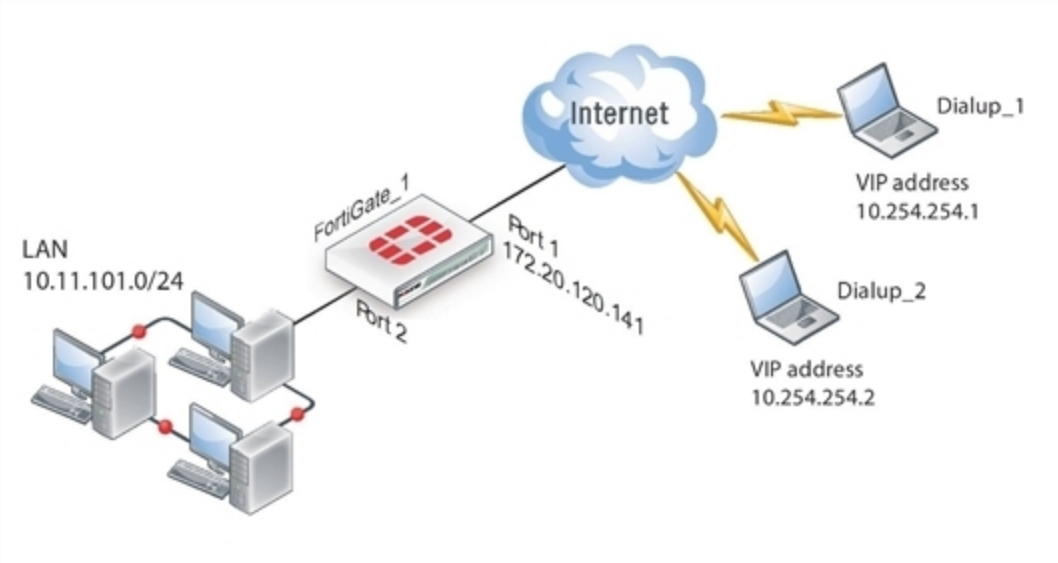
For more information on configuring XAuth authentication, see the FortiClient Administration Guide.

FortiClient dialup-client configuration example

This example demonstrates how to set up a FortiClient dialup-client IPsec VPN that uses preshared keys for authentication purposes. In the example configuration, the DHCP over IPsec feature is enabled in the FortiClient

Endpoint Security application so that the FortiClient Endpoint Security application can acquire a VIP address through the FortiGate DHCP server. Both route-based and policy-based solutions are covered.

Example FortiClient dialup-client configuration



In the example configuration:

- VIP addresses that are not commonly used (in this case, 10.254.254.0/24) are assigned to the FortiClient dialup clients using a DHCP server.
- The dialup clients are have access to the LAN behind FortiGate_1.
- The other network devices are assigned IP addresses as shown above.

Configuring FortiGate_1

When a FortiGate unit receives a connection request from a dialup client, it uses IPsec Phase 1 parameters to establish a secure connection and authenticate the client. Then, if the security policy permits the connection, the FortiGate unit establishes the tunnel using IPsec Phase 2 parameters and applies the IPsec security policy. Key management, authentication, and security services are negotiated dynamically through the IKE protocol.

To support these functions, the following general configuration steps must be performed at the FortiGate unit:

- Define the Phase 1 parameters that the FortiGate unit needs to authenticate the dialup clients and establish a secure connection. See To define the Phase 1 parameters on page 1665.
- Define the Phase 2 parameters that the FortiGate unit needs to create a VPN tunnel and enable all dialup clients having VIP addresses on the 10.254.254.0/24 network to connect using the same tunnel definition. See To define the Phase 2 parameters on page 1665.
- Create security policy to control the permitted services and permitted direction of traffic between the IP source address and the dialup clients. See To define the firewall addresses on page 1665.
- Configure the FortiGate unit to service DHCP requests from dialup clients. See Configuring the FortiClient Endpoint Security application on page 1667.

To define the Phase 1 parameters

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**:

Name	todialups
Remote Gateway	Dialup User
Local Interface	Port 1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	hardtoguess
Peer Options	Any peer ID
Advanced	Select

To define the Phase 2 parameters

1. Open the **Phase 2 Selectors** panel.
2. Select **Advanced**, enter the following information, and select **OK**:

Name	td_2
Phase 1	todialups
Advanced	DHCP-IPsec

To define the firewall addresses

1. Go to **Policy & Objects > Objects > Addresses**.
2. Select **Create New**, enter the following information, and select **OK**:

Name	internal_net
Type	Subnet
Subnet/IP Range	10.11.101.0/24
Interface	Port 2

3. Select **Create New**, enter the following information, and select **OK**:

Name	dialups
Type	IP Range

Subnet/IP Range	10.254.254.1-10.254.254.10
Interface	Route-based VPN: todialups Policy-based VPN: Any

The security policies for route-based and policy-based VPNs are described in separate sections below.

To define security policies - route-based VPN

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information, and select **OK**:

Incoming Interface	todialups
Source Address	dialups
Outgoing Interface	Port 2
Destination Address	internal_net
Action	ACCEPT
Enable NAT	Disable

4. Select **Create New**.
5. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
6. Enter the following information, and select **OK**:

Incoming Interface	Port 2
Source Address	internal_net
Outgoing Interface	todialups
Destination Address	dialups
Action	ACCEPT
Enable NAT	Disable

7. Select **Create New**.
8. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
9. Enter the following information, and select **OK**:

Incoming Interface	Port 2
Source Address	internal_net

Outgoing Interface	todialups
Destination Address	all
Service	DHCP
Action	ACCEPT
Enable NAT	Disable

10. Place these policies in the policy list above any other policies having similar source and destination addresses.

The policy in step "FortiClient dialup-client configuration example" on page 1663 is required for DHCP to function properly for policy-based VPNs. You can omit this policy if you change the **Destination Address Name** to `all` in the step before. Route-based policies are not affected by this.

To define the security policy - policy-based VPN

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Port 2
Source Address	internal_net
Outgoing Interface	Port 1
Destination Address	dialups
VPN Tunnel	Select **Use Existing** and select **todialups** from the drop-down list.
Allow traffic to be initiated from the remote site	Enable

3. Place the policy in the policy list above any other policies having similar source and destination addresses.

Configuring the FortiClient Endpoint Security application

The following procedure explains how to configure the FortiClient Endpoint Security application to connect to FortiGate_1 and broadcast a DHCP request. The dialup client uses the VIP address acquired through FortiGate DHCP relay as its IP source address for the duration of the connection.

To configure FortiClient

1. Go to **Remote Access** and select the down-arrow for the VPN connection.
2. Select **Add new connection** and complete following information:

VPN Type	Select **IPsec VPN**.
Connection Name	Headquarters.
Remote Gateway	The port1 IP address.

Authentication Method	Select **Pre-shared Key**.
Pre-shared Key	hardtoguess
User Name	Enter the user name to connect to the tunnel.

3. Select **OK**.

FortiGate dialup-client configurations

This section explains how to set up a FortiGate dialup-client IPsec VPN. In a FortiGate dialup-client configuration, a FortiGate unit with a static IP address acts as a dialup server and a FortiGate unit having a dynamic IP address initiates a VPN tunnel with the FortiGate dialup server.

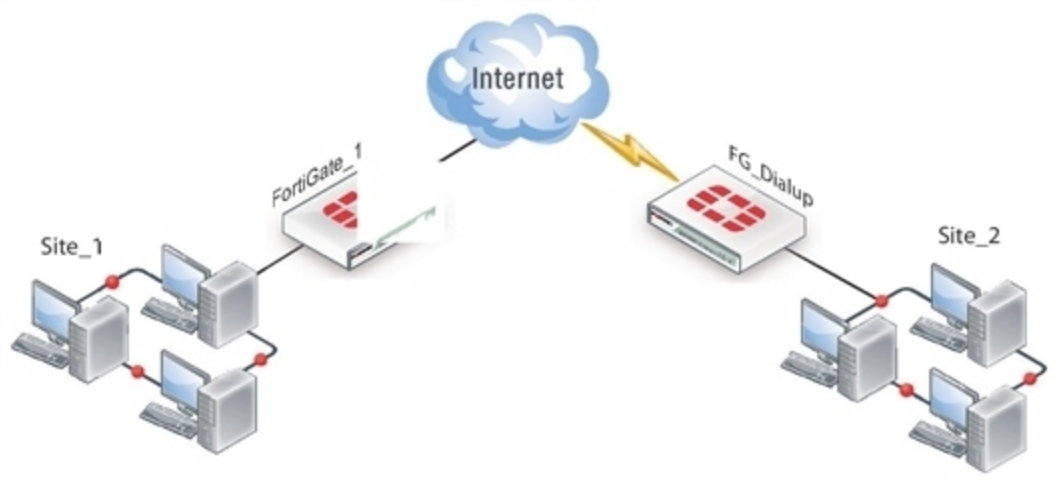
The following topics are included in this section:

Configuration overview
FortiGate dialup-client configuration steps
Configure the server to accept FortiGate dialup-client connections
Configure the FortiGate dialup client

Configuration overview

A dialup client can be a FortiGate unit. The FortiGate dialup client typically obtains a dynamic IP address from an ISP through the Dynamic Host Configuration Protocol (DHCP) or Point-to-Point Protocol over Ethernet (PPPoE) before initiating a connection to a FortiGate dialup server.

Example FortiGate dialup-client configuration



In a dialup-client configuration, the FortiGate dialup server does not rely on a Phase 1 remote gateway address to establish an IPsec VPN connection with dialup clients. As long as authentication is successful and the IPsec security policy associated with the tunnel permits access, the tunnel is established.

Several different ways to authenticate dialup clients and restrict access to private networks based on client credentials are available. To authenticate FortiGate dialup clients and help to distinguish them from FortiClient dialup clients when multiple clients will be connecting to the VPN through the same tunnel, best practices dictate that you assign a unique identifier (local ID or peer ID) to each FortiGate dialup client. For more information, see Phase 1 parameters on page 1581.

Whenever you add a unique identifier (local ID) to a FortiGate dialup client for identification purposes, you must select Aggressive mode on the FortiGate dialup server and also specify the identifier as a peer ID on the FortiGate dialup server. For more information, see Phase 1 parameters on page 1581.

Users behind the FortiGate dialup server cannot initiate the tunnel because the FortiGate dialup client does not have a static IP address. After the tunnel is initiated by users behind the FortiGate dialup client, traffic from the private network behind the FortiGate dialup server can be sent to the private network behind the FortiGate dialup client.

Encrypted packets from the FortiGate dialup client are addressed to the public interface of the dialup server. Encrypted packets from the dialup server are addressed either to the public IP address of the FortiGate dialup client (if the dialup client connects to the Internet directly), or if the FortiGate dialup client is behind a NAT device, encrypted packets from the dialup server are addressed to the public IP address of the NAT device.

If a router with NAT capabilities is in front of the FortiGate dialup client, the router must be NAT-T compatible for encrypted traffic to pass through the NAT device. For more information, see Phase 1 parameters on page 1581.

When the FortiGate dialup server decrypts a packet from the FortiGate dialup client, the source address in the IP header may be one of the following values, depending on the configuration of the network at the far end of the tunnel:

- If the FortiGate dialup client connects to the Internet directly, the source address will be the private IP address of a host or server on the network behind the FortiGate dialup client.
- If the FortiGate dialup client is behind a NAT device, the source address will be the public IP address of the NAT device.

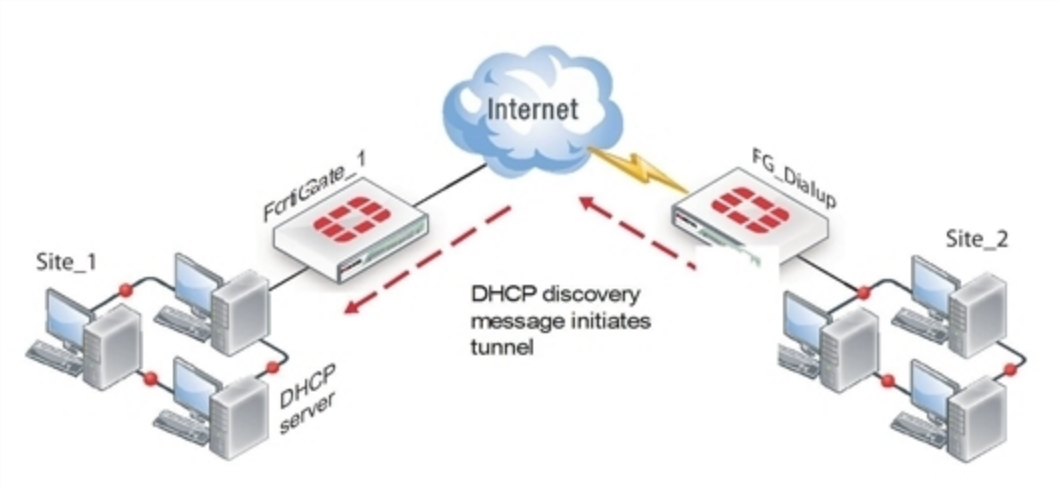
In some cases, computers on the private network behind the FortiGate dialup client may (by co-incidence) have IP addresses that are already used by computers on the network behind the FortiGate dialup server. In this type of situation (ambiguous routing), conflicts may occur in one or both of the FortiGate routing tables and traffic destined for the remote network through the tunnel may not be sent.

In many cases, computers on the private network behind the FortiGate dialup client will most likely obtain IP addresses from a local DHCP server behind the FortiGate dialup client. However, unless the local and remote networks use different private network address spaces, unintended ambiguous routing and IP-address overlap issues may arise.

To avoid these issues, you can configure FortiGate DHCP relay on the dialup client instead of using a DHCP server on the network behind the dialup client. The FortiGate dialup client can be configured to relay DHCP requests from the local private network to a DHCP server that resides on the network behind the FortiGate dialup server. You configure the FortiGate dialup client to pass traffic from the local private network to the remote network by enabling FortiGate DHCP relay on the FortiGate dialup client interface that is connected to the local private network.

Afterward, when a computer on the network behind the dialup client broadcasts a DHCP request, the dialup client relays the message through the tunnel to the remote DHCP server. The remote DHCP server responds with a private IP address for the computer. To avoid ambiguous routing and network overlap issues, the IP addresses assigned to computers behind the dialup client cannot match the network address space used by the private network behind the FortiGate dialup server.

Preventing network overlap in a FortiGate dialup-client configuration



When the DHCP server resides on the private network behind the FortiGate dialup server, the IP destination address specified in the IPsec security policy on the FortiGate dialup client must refer to that network.

You must add a static route to the DHCP server FortiGate unit if it is not directly connected to the private network behind the FortiGate dialup server; its IP address does not match the IP address of the private network. Also, the destination address in the IPsec security policy on the FortiGate dialup client must refer to the DHCP server address. The DHCP server must be configured to assign a range of IP addresses different from the DHCP server's local network, and also different from the private network addresses behind the FortiGate dialup server. See Dynamic DNS configuration on page 1639.

FortiGate dialup-client infrastructure requirements

The requirements are:

- The FortiGate dialup server must have a static public IP address.
- NAT mode is required if you want to create a route-based VPN.
- The FortiGate dialup server may operate in either NAT mode or transparent mode to support a policy-based VPN.
- Computers on the private network behind the FortiGate dialup client can obtain IP addresses either from a DHCP server behind the FortiGate dialup client, or a DHCP server behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the dialup client, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup server.
  - If the DHCP server resides on the network behind the FortiGate dialup server, the DHCP server must be configured to assign IP addresses that do not match the private network behind the FortiGate dialup client.

FortiGate dialup-client configuration steps

The procedures in this section assume that computers on the private network behind the FortiGate dialup client obtain IP addresses from a local DHCP server. The assigned IP addresses do not match the private network behind the FortiGate dialup server.

In situations where IP-address overlap between the local and remote private networks is likely to occur, FortiGate DHCP relay can be configured on the FortiGate dialup client to relay DHCP requests to a DHCP server behind the FortiGate dialup server. For more information, see FortiClient dialup-client configurations on page 1654.

Configuring dialup client capability for FortiGate dialup clients involves the following general configuration steps:

- Determine which IP addresses to assign to the private network behind the FortiGate dialup client, and add the IP addresses to the DHCP server behind the FortiGate dialup client. Refer to the software supplier's documentation to configure the DHCP server.
- Configure the FortiGate dialup server. See FortiGate dialup-client configuration steps on page 1671.
- Configure the FortiGate dialup client. See FortiGate dialup-client configuration steps on page 1671.

Configure the server to accept FortiGate dialup-client connections

Before you begin, optionally reserve a unique identifier (peer ID) for the FortiGate dialup client. The dialup client will supply this value to the FortiGate dialup server for authentication purposes during the IPsec Phase 1 exchange. In addition, the value will enable you to distinguish FortiGate dialup-client connections from FortiClient dialup-client connections. The same value must be specified on the dialup server and on the dialup client.

1. At the FortiGate dialup server, define the Phase 1 parameters needed to authenticate the FortiGate dialup client and establish a secure connection. See Phase 1 parameters on page 1581. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel. This name appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	Select **Dialup User**.
Local Interface	Select the interface through which clients connect to the FortiGate unit.
Mode	If you will be assigning an ID to the FortiGate dialup client, select **Aggressive**.
Peer Options	If you will be assigning an ID to the FortiGate dialup client, select **This peer ID** and type the identifier that you reserved for the FortiGate dialup client into the adjacent field.

2. Define the Phase 2 parameters needed to create a VPN tunnel with the FortiGate dialup client. See Phase 2 parameters on page 1598. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

3. Define names for the addresses or address ranges of the private networks that the VPN links. See Defining VPN security policies on page 1603. Enter these settings in particular:
   - Define an address name for the server, host, or network behind the FortiGate dialup server.
   - Define an address name for the private network behind the FortiGate dialup client.

4. Define the security policies to permit communications between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1603.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind the FortiGate dialup client and the private network behind this FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Source Address	Select **All**.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	Select **All**.
Action	Select **ACCEPT**.
Enable NAT	Disable

Policy-based VPN security policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select the address name that you defined for the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	Select the address name that you defined.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created in Step1. from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel. Clear **Allow outbound** to prevent traffic from the local network from initiating the tunnel after the tunnel has been established.

3. To prevent traffic from the local network from initiating the tunnel after the tunnel has been established, you need to disable the outbound VPN traffic in the CLI

```
config firewall policy
   edit <policy_number>
      set outbound disable
end
```

Place the policy in the policy list above any other policies having similar source and destination addresses.

If configuring a route-based policy, configure a default route for VPN traffic on this interface.

Configure the FortiGate dialup client

Configure the FortiGate dialup client.

1. At the FortiGate dialup client, define the Phase 1 parameters needed to authenticate the dialup server and establish a secure connection. See Phase 1 parameters on page 1581. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel.
Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the dialup server's public interface.
Local Interface	Select the interface that connects to the public network.
Mode	The FortiGate dialup client has a dynamic IP address, select **Aggressive**.
Advanced	Select to view the following options.
Local ID	If you defined a peer ID for the dialup client in the FortiGate dialup server configuration, enter the identifier of the dialup client. The value must be identical to the peer ID that you specified previously in the FortiGate dialup server configuration.

2. Define the Phase 2 parameters needed to create a VPN tunnel with the dialup server. See Phase 2 parameters on page 1598. Enter these settings in particular:

Name	Enter a name to identify this Phase 2 configuration.
Phase 1	Select the name of the Phase 1 configuration that you defined.

3. Define names for the addresses or address ranges of the private networks that the VPN links. See Defining VPN security policies on page 1603. Enter these settings in particular:
   - Define an address name for the server, host, or network behind the FortiGate dialup server.
   - Define an address name for the private network behind the FortiGate dialup client.
4. Define security policies to permit communication between the private networks through the VPN tunnel. Route-based and policy-based VPNs require different security policies. For detailed information about creating security policies, see Defining VPN security policies on page 1603.

Route-based VPN security policy

Define an ACCEPT security policy to permit communications between hosts on the private network behind this FortiGate dialup client and the private network behind the FortiGate dialup server. Because communication cannot be initiated in the opposite direction, there is only one policy.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** of **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select **All**.
Outgoing Interface	Select the VPN tunnel (IPsec interface) created in Step 1.
Destination Address	Select **All**.
Action	Select **ACCEPT**.
Enable NAT	Disable

Policy-based VPN security policy

Define an IPsec security policy to permit communications between the source and destination addresses.

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter these settings in particular:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	Select the address name that you defined for the private network behind this FortiGate unit.
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	Select the address name that you defined for the private network behind the dialup server.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created in Step "Configure the FortiGate dialup client " on page 1674 from the drop-down list. Clear **Allow traffic to be initiated from the remote site** to prevent traffic from the remote network from initiating the tunnel after the tunnel has been established.

Place the policy in the policy list above any other policies having similar source and destination addresses.

Supporting IKE Mode config clients

IKE Mode Config is an alternative to DHCP over IPsec. A FortiGate unit can be configured as either an IKE Mode Config server or client. This chapter contains the following sections:

Automatic configuration overview
IKE Mode Config overview
Configuring IKE Mode Config
Example FortiGate unit as IKE Mode Config server
Example FortiGate unit as IKE Mode Config client

Automatic configuration overview

VPN configuration for remote clients is simpler if it is automated. Several protocols support automatic configuration:

- The Fortinet FortiClient Endpoint Security application can completely configure a VPN connection with a suitably configured FortiGate unit given only the FortiGate unit's address. This protocol is exclusive to Fortinet. For more information, see FortiClient dialup-client configurations on page 1654.
- DHCP over IPsec can assign an IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms.
- IKE Mode Config can configure host IP address, Domain, DNS and WINS addresses. The user must first configure IPsec parameters such as gateway address, encryption and authentication algorithms. Several network equipment vendors support IKE Mode Config, which is described in the ISAKMP Configuration Method document draft-dukes-ike-mode-cfg-02.txt.

This chapter describes how to configure a FortiGate unit as either an IKE Mode Config server or client.

IKE Mode Config overview

Dialup VPN clients connect to a FortiGate unit that acts as a VPN server, providing the client the necessary configuration information to establish a VPN tunnel. The configuration information typically includes a virtual IP address, netmask, and DNS server address.

IKE Mode Config is available only for VPNs that are route-based, also known as interface-based. A FortiGate unit can function as either an IKE Configuration Method server or client. IKE Mode Config is configurable only in the CLI.

Configuring IKE Mode Config

IKE Mode Config is configured with the CLI command `config vpn ipsec phase1-interface`. The `mode-cfg` variable enables IKE Mode Config. The `type` field determines whether you are creating an IKE Mode Config server or a client. Setting `type` to `dynamic` creates a server configuration, otherwise the configuration is a client.

Configuring an IKE Mode Config client

If the FortiGate unit will connect as a dialup client to a remote gateway that supports IKE Mode Config, the relevant `vpn ipsec phase1-interface` variables are as follows:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax `ike-version 2`.
`mode-cfg enable`	Enable IKE Mode Config.
`type {ddns | static}`	If you set `type` to `dynamic`, an IKE Mode Config server is created.
`assign-ip {enable | disable}`	Enable to request an IP address from the server.
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the client will accept. For more information, see Phase 1 parameters on page 1581.
`mode-cfg-ip-version {4|6}`	Select if the Method client receives an IPv4 or IPv6 IP address. The default is `4`. the `ip-version` setting matches this variable's value.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

For a complete list of available variables, see the CLI Reference.

Configuring an IKE Mode Config server

If the FortiGate unit will accept connection requests from dialup clients that support IKE Mode Config, the following `vpn ipsec phase1-interface` settings are required before any other configuration is attempted:

Variable	Description
`ike-version 1`	IKE v1 is the default for FortiGate IPsec VPNs. IKE Mode Config is also compatible with IKE v2 (RFC 4306). Use syntax `ike-version 2`.
`mode-cfg enable`	Enable IKE Mode Config.
`type dynamic`	Any other setting creates an IKE Mode Config client.
`interface <interface_name>`	This is a regular IPsec VPN field. Specify the physical, aggregate, or VLAN interface to which the IPsec tunnel will be bound.
`proposal <encryption_combination>`	This is a regular IPsec VPN field that determines the encryption and authentication settings that the server will accept. For more information, see Phase 1 parameters on page 1581.
`ip-version <4 | 6>`	This is a regular IPsec VPN field. By default, IPsec VPNs use IPv4 addressing. You can set `ip-version` to `6` to create a VPN with IPv6 addressing.

For a complete list of available variables, see the CLI Reference.

After you have enabled the basic configuration, you can configure:

- IP address assignment for clients
- DNS and WINS server assignment

IP address assignment

Usually you will want to assign IP addresses to clients. The simplest method is to assign addresses from a specific range, similar to a DHCP server.

If your clients are authenticated by a RADIUS server, you can obtain the user's IP address assignment from the Framed-IP-Address attribute. The user must be authenticated using XAuth.

IKE Mode Config can also use a remote DHCP server to assign the client IP addresses. Up to eight addresses can be selected for either IPv4 or IPv6. After the DHCP proxy has been configured, the `assign-ip-from` command is used to assign IP addresses via DHCP.

To assign IP addresses from an address range - CLI

If your VPN uses IPv4 addresses,

```
config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg-ipversion 4
      set assign-ip enable
      set assign-ip-type ip
      set assign-ip-from range
      set ipv4-start-ip <range_start>
      set ipv4-end-ip <range_end>
      set ipv4-netmask <netmask>
```

```
   end
```

If your VPN uses IPv6 addresses,

```
config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg-ipversion 6
      set assign-ip enable
      set assign-ip-type ip
      set assign-ip-from range
      set ipv6-start-ip <range_start>
      set ipv6-end-ip <range_end>
   end
```

To assign IP addresses from a RADIUS server - CLI

The users must be authenticated by a RADIUS server and assigned to the FortiGate user group `<grpname>`. Since the IP address will not be static, `type` is set to dynamic, and `mode-cfg` is enabled. This is IKE Configuration Method so that compatible clients can configure themselves with settings that the FortiGate unit provides.

```
config vpn ipsec phase1-interface
   edit vpn1
      set type dynamic
         set mode-cfg enable
         set assign-ip enable
         set assign-ip-from usrgrp
         set xauthtype auto
         set authusrgrp <grpname>
   end
```

To assign IP address from DHCP - CLI

The DHCP proxy must first be enabled for IKE Mode Config to use DHCP to assign the VPN client IP address(es).

```
config system settings
   set dhcp-proxy enable
   set dhcp-server-ip [ipv4 address]
   set dhcp6-server-ip [ipv6-address]
```

(Up to 8 server addresses can be configured)

```
end

config vpn ipsec phase1-interface
   edit vpn1
      set mode-cfg enable
      set assign-ip-from dhcp
   next
end
```

Certificate groups

IKE certificate groups consisting of up to four RSA certificates can be used in IKE Phase 1. Since CA and local certificates are global, the IKE daemon loads them once for all VDOMs and indexes them into trees based on subject and public key hash (for CA certificates), or certificate name (for local certicates). Certifcates are linked

together based on the issuer, and certificate chains are built by traversing these links. This reduces the need to keep multiple copies of certificates that could exist in multiple chains.

IKE certificate groups can be configured through the CLI.

Configuring the IKE local ID (CLI):

```
config vpn certificate local
edit <name>
   set ike-localid <string>
   set ike-localid-type {asnldn | fqdn}
end
```

Example FortiGate unit as IKE Mode Config server

In this example, the FortiGate unit assigns IKE Mode Config clients addresses in the range of 10.11.101.160 through 10.11.101.180. DNS and WINS server addresses are also provided. The public interface of the FortiGate unit is Port 1.

When IKE Mode-Configuration is enabled, multiple server IPs can be defined in IPsec Phase 1.

The `ipv4-split-include` variable specifies a firewall address that represents the networks to which the clients will have access. This destination IP address information is sent to the clients.

Only the CLI fields required for IKE Mode Config are shown here. For detailed information about these variables, see the FortiGate CLI Reference.

```
config vpn ipsec phase1-interface
edit "vpn-p1"
   set type dynamic
   set interface "wan1"
   set xauthtype auto
   set mode aggressive
   set mode-cfg enable
   set proposal 3des-sha1 aes128-sha1
   set dpd disable
   set dhgrp 2
   set xauthexpire on-rekey
   set authusrgrp "FG-Group1"
   set ipv4-start-ip 10.10.10.10
   set ipv4-end-ip 10.10.10.20
   set ipv4-dns-server1 1.1.1.1
   set ipv4-dns-server2 2.2.2.2
   set ipv4-dns-server3 3.3.3.3
   set ipv4-wins-server1 4.4.4.4
   set ipv4-wins-server2 5.5.5.5
   set domain "fgt1c-domain"
   set banner "fgt111C-banner"
   set backup-gateway "100.100.100.1" "host1.com" "host2"
   set ipv4-split-include OfficeLAN
end
```

Example FortiGate unit as IKE Mode Config client

In this example, the FortiGate unit connects to a VPN gateway with a static IP address that can be reached through Port 1. Only the port, gateway and proposal information needs to be configured. All other configuration

information will come from the IKE Mode Config server.

```
config vpn ipsec phase1-interface
   edit vpn1
      set ip-version 4
      set type static
      set remote-gw <gw_address>
      set interface port 1
      set proposal 3des-sha1 aes128-sha1
      set mode-cfg enable
      set mode-cfg-ipversion 4
      set assign-ip enable
   end
```

Internet-browsing configuration

This section explains how to support secure web browsing performed by dialup VPN clients, and/or hosts behind a remote VPN peer. Remote users can access the private network behind the local FortiGate unit and browse the Internet securely. All traffic generated remotely is subject to the security policy that controls traffic on the private network behind the local FortiGate unit.

The following topics are included in this section:

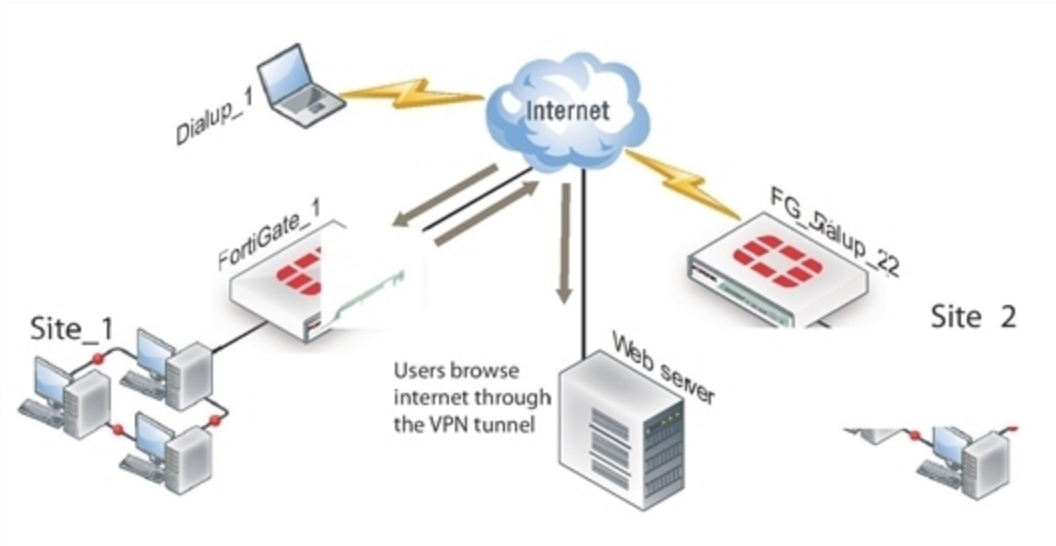
Configuration overview
Creating an Internet browsing security policy
Routing all remote traffic through the VPN tunnel

Configuration overview

A VPN provides secure access to a private network behind the FortiGate unit. You can also enable VPN clients to access the Internet securely. The FortiGate unit inspects and processes all traffic between the VPN clients and hosts on the Internet according to the Internet browsing policy. This is accomplished even though the same FortiGate interface is used for both encrypted VPN client traffic and unencrypted Internet traffic.

In the figure below, FortiGate_1 enables secure Internet browsing for FortiClient Endpoint Security users such as Dialup_1 and users on the Site_2 network behind FortiGate_2, which could be a VPN peer or a dialup client.

Example Internet-browsing configuration



You can adapt any of the following configurations to provide secure Internet browsing:

- A gateway-to-gateway configuration (see Gateway-to-gateway configurations on page 1609)
- A FortiClient dialup-client configuration (see FortiClient dialup-client configurations on page 1654)
- A FortiGate dialup-client configuration (see FortiGate dialup-client configurations on page 1669)

The procedures in this section assume that one of these configurations is in place, and that it is operating properly.

To create an internet-browsing configuration based on an existing gateway-to-gateway configuration, you must edit the gateway-to-gateway configuration as follows:

- On the FortiGate unit that will provide Internet access, create an Internet browsing security policy. See Configuration overview on page 1682, below.
- Configure the remote peer or client to route all traffic through the VPN tunnel. You can do this on a FortiGate unit or on a FortiClient Endpoint Security application. See Configuration overview on page 1682.

Creating an Internet browsing security policy

On the FortiGate unit that acts as a VPN server and will provide secure access to the Internet, you must create an Internet browsing security policy. This policy differs depending on whether your gateway-to-gateway configuration is policy-based or route-based.

To create an Internet browsing policy - policy-based VPN

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information and then select **OK**:

Incoming Interface	The interface to which the VPN tunnel is bound.
Source Address	The internal range address of the remote spoke site.
Outgoing Interface	The interface to which the VPN tunnel is bound.
Destination Address	All
VPN Tunnel	Select **Use Existing** and select the tunnel that provides access to the private network behind the FortiGate unit.
Allow traffic to be initiated from the remote site	Enable
Inbound NAT	Enable

3. Enable inbound NAT in the CLI.

```
config firewall policy
   edit <policy_number>
      set natinbound enable
end
```

To create an Internet browsing policy - route-based VPN

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information and then select **OK**:

Incoming Interface	The IPsec VPN interface.

Source Address	The internal range address of the remote spoke site.
Outgoing Interface	The interface that connects to the Internet. The virtual IPsec interface is configured on this physical interface.
Destination Address	All
Action	ACCEPT
Enable NAT	Enable

The VPN clients must be configured to route all Internet traffic through the VPN tunnel.

Routing all remote traffic through the VPN tunnel

To make use of the Internet browsing configuration on the VPN server, the VPN peer or client must route all traffic through the VPN tunnel. Usually, only the traffic destined for the private network behind the FortiGate VPN server is sent through the tunnel.

The remote end of the VPN can be a FortiGate unit that acts as a peer in a gateway-to-gateway configuration, or a FortiClient application that protects an individual client PC.

- To configure a remote peer FortiGate unit for Internet browsing via VPN, see Configuring a FortiGate remote peer to support Internet browsing on page 1684.
- To configure a FortiClient Endpoint Security application for Internet browsing via VPN, see Configuring a FortiClient application to support Internet browsing on page 1685.

These procedures assume that your VPN connection to the protected private network is working and that you have configured the FortiGate VPN server for Internet browsing as described in Routing all remote traffic through the VPN tunnel on page 1684.

Configuring a FortiGate remote peer to support Internet browsing

The configuration changes to send all traffic through the VPN differ for policy-based and route-based VPNs.

To route all traffic through a policy-based VPN

1. At the FortiGate dialup client, go to **Policy & Objects > Policy > IPv4**.
2. Select the IPsec security policy and then select **Edit**.
3. From the **Destination Address** list, select **all**.
4. Select **OK**.

Packets are routed through the VPN tunnel, not just those destined for the protected private network.

To route all traffic through a route-based VPN

1. At the FortiGate dialup client, go to **Router > Static > Static Route**s.
2. On a low-end FortiGate unit, go to **System > Network > Routing**.
3. Select the default route (destination IP 0.0.0.0) and then select ***Edit***. If there is no default route, select **Create New**. Enter the following information and select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	Select the IPsec virtual interface.
Distance	Leave at default.

All packets are routed through the VPN tunnel, not just packets destined for the protected private network.

Configuring a FortiClient application to support Internet browsing

By default, the FortiClient application configures the PC so that traffic destined for the remote protected network passes through the VPN tunnel but all other traffic is sent to the default gateway. You need to modify the FortiClient settings so that it configures the PC to route all outbound traffic through the VPN.

To route all traffic through VPN - FortiClient application

1. At the remote host, start FortiClient.
2. Go to **VPN > Connections**.
3. Select the definition that connects FortiClient to the FortiGate dialup server.
4. Select **Advanced** and then select **Edit**.
5. In the **Edit Connection** dialog box, select **Advanced**.
6. In the **Remote Network** group, select **Add**.
7. In the **IP** and **Subnet Mask** fields, type `0.0.0.0/0.0.0.0` and select **OK**.
   The address is added to the **Remote Network** list. The first destination IP address in the list establishes a VPN tunnel. The second destination address (`0.0.0.0/0.0.0.0` in this case) forces all other traffic through the VPN tunnel.
8. Select **OK**.

Redundant VPN configurations

This section discusses the options for supporting redundant and partially redundant IPsec VPNs, using route-based approaches.

The following topics are included in this section:

Configuration overview
General configuration steps
Configure the VPN peers - route-based VPN
Redundant route-based VPN configuration example
Partially-redundant route-based VPN example
Creating a backup IPsec interface

Configuration overview

A FortiGate unit with two interfaces connected to the Internet can be configured to support redundant VPNs to the same remote peer. If the primary connection fails, the FortiGate unit can establish a VPN using the other connection.

Redundant tunnels do not support Tunnel Mode or manual keys. You must use Interface Mode.

A fully-redundant configuration requires redundant connections to the Internet on both peers. The figure below shows an example of this. This is useful to create a reliable connection between two FortiGate units with static IP addresses.

When only one peer has redundant connections, the configuration is partially-redundant. For an example of this, see Configuration overview on page 1686. This is useful to provide reliable service from a FortiGate unit with static IP addresses that accepts connections from dialup IPsec VPN clients.

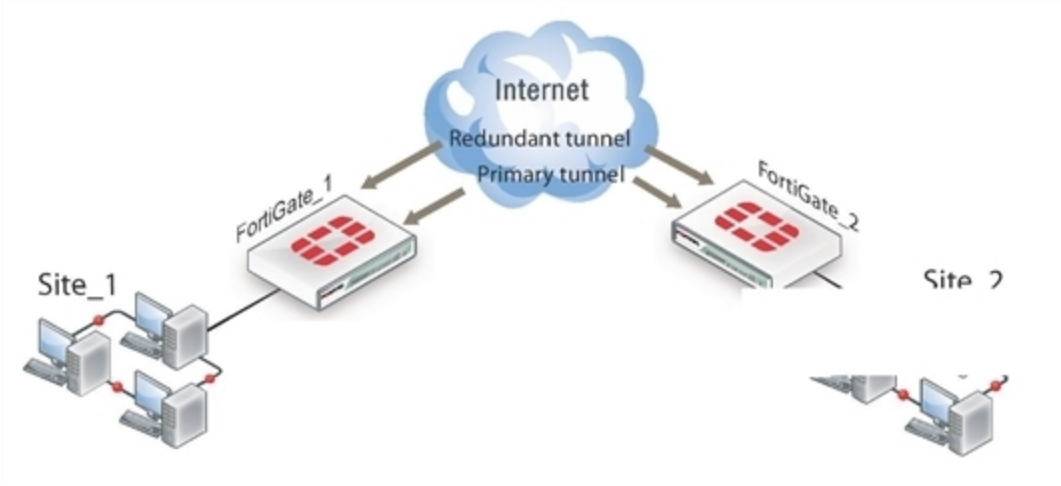
In a fully-redundant VPN configuration with two interfaces on each peer, four distinct paths are possible for VPN traffic from end to end. Each interface on a peer can communicate with both interfaces on the other peer. This ensures that a VPN will be available as long as each peer has one working connection to the Internet.

You configure a VPN and an entry in the routing table for each of the four paths. All of these VPNs are ready to carry data. You set different routing distances for each route and only the shortest distance route is used. If this route fails, the route with the next shortest distance is used.

The redundant configurations described in this chapter use route-based VPNs, otherwise known as virtual IPsec interfaces. This means that the FortiGate unit must operate in NAT mode. You must use auto-keying. A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

The configuration described here assumes that your redundant VPNs are essentially equal in cost and capability. When the original VPN returns to service, traffic continues to use the replacement VPN until the replacement VPN fails. If your redundant VPN uses more expensive facilities, you want to use it only as a backup while the main VPN is down. For information on how to do this, see Configuration overview on page 1686.

Example redundant-tunnel configuration



A VPN that is created using manual keys cannot be included in a redundant-tunnel configuration.

General configuration steps

A redundant configuration at each VPN peer includes:

- One Phase 1 configuration (virtual IPsec interface) for each path between the two peers. In a fully-meshed redundant configuration, each network interface on one peer can communicate with each network interface on the remote peer. If both peers have two public interfaces, this means that each peer has four paths, for example.
- One Phase 2 definition for each Phase 1 configuration.
- One static route for each IPsec interface, with different distance values to prioritize the routes.
- Two Accept security policies per IPsec interface, one for each direction of traffic.
- Dead peer detection enabled in each Phase 1 definition.

The procedures in this section assume that two separate interfaces to the Internet are available on each VPN peer.

Configure the VPN peers - route-based VPN

VPN peers are configured using Interface Mode for redundant tunnels.

Configure each VPN peer as follows:

1. Ensure that the interfaces used in the VPN have static IP addresses.
2. Create a Phase 1 configuration for each of the paths between the peers.
3. Enable dead peer detection so that one of the other paths is activated if this path fails.
4. Enter these settings in particular, and any other VPN settings as required:

Path 1

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 2

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the primary public interface of this peer.
Dead Peer Detection	Enable

Path 3

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the primary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

Path 4

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the secondary interface of the remote peer.
Local Interface	Select the secondary public interface of this peer.
Dead Peer Detection	Enable

For more information, see Phase 1 parameters on page 1581.

5. Create a Phase 2 definition for each path. See Phase 2 parameters on page 1598. Select the Phase 1 configuration (virtual IPsec interface) that you defined for this path. You can select the name from the Static IP Address part of the list.
6. Create a route for each path to the other peer. If there are two ports on each peer, there are four possible paths between the peer devices.

Destination IP/Mask	The IP address and netmask of the private network behind the remote peer.
Device	One of the virtual IPsec interfaces on the local peer.
Distance	For each path, enter a different value to prioritize the paths.

7. Define the security policy for the local primary interface. See Defining VPN security policies on page 1603. You need to create two policies for each path to enable communication in both directions. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	All
Outgoing Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

8. Select **Create New**, leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**, and enter these settings:

Incoming Interface	Select one of the virtual IPsec interfaces you created in Step 2.
Source Address	All
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

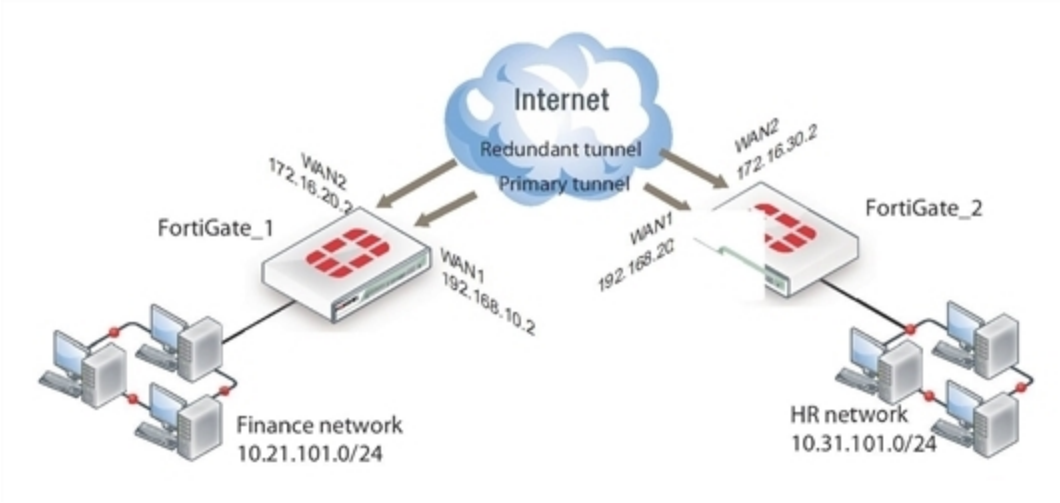
9. Place the policy in the policy list above any other policies having similar source and destination addresses.
10. Repeat this procedure at the remote FortiGate unit.

Redundant route-based VPN configuration example

This example demonstrates a fully redundant site-to-site VPN configuration using route-based VPNs. At each site, the FortiGate unit has two interfaces connected to the Internet through different ISPs. This means that there are four possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate_1 WAN 1 to FortiGate_2 WAN 1
- FortiGate_1 WAN 1 to FortiGate_2 WAN 2
- FortiGate_1 WAN 2 to FortiGate_2 WAN 1
- FortiGate_1 WAN 2 to FortiGate_2 WAN 2

Example redundant route-based VPN configuration



For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

Configuring FortiGate_1

When configuring FortiGate_1, you must:

- Configure the interfaces involved in the VPN.
- Define the Phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one.
- Define the Phase 2 configuration for each of the four possible paths.
- Configure routes for the four IPsec interfaces, assigning the appropriate priorities.
- Configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces.

To configure the network interfaces

1. Go to **System > Network > Interfaces**.
2. Select the Internal interface and select **Edit**.

3. Enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`10.21.101.0/255.255.255.0`

4. Select the WAN1 interface and select **Edit**, enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`192.168.10.2/255.255.255.0`

5. Select the WAN2 interface and select **Edit**, enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`172.16.20.2/255.255.255.0`

To configure the IPsec interfaces (Phase 1 configurations)

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**:

Name	`Site_1_A`
Remote Gateway	Static IP Address
IP Address	`192.168.20.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

4. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_1_B`
Remote Gateway	Static IP Address
IP Address	`172.16.30.2`

Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

5. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_1_C`
Remote Gateway	Static IP Address
IP Address	`192.168.20.2`
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

6. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_1_D`
Remote Gateway	Static IP Address
IP Address	`172.16.30.2`
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID

Advanced	
Dead Peer Detection	Select

To define the Phase 2 configurations for the four VPNs

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and select **OK**:

Name	`Route_A`
Phase 1	Site_1_A

3. Enter the following Phase 2 information for the subsequent route:

Name	`Route_B`
Phase 1	Site_1_B

4. Enter the following Phase 2 information for the subsequent route:

Name	`Route_C`
Phase 1	Site_1_C

5. Enter the following Phase 2 information for the subsequent route:

Name	`Route_D`
Phase 1	Site_1_D

To configure routes

1. Go to **Router > Static > Static Routes**.
   For low-end FortiGate units, go to **System > Network > Routing**.
2. Select **Create New**, enter the following default gateway information and then select **OK**:

Destination IP/Mask	`0.0.0.0/0.0.0.0`
Device	WAN1
Gateway	`192.168.10.1`
Distance (Advanced)	`10`

3. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	`10.31.101.0/255.255.255.0`

Device	Site_1_A
Distance (Advanced)	1

4. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_B
Distance (Advanced)	2

5. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_C
Distance (Advanced)	3

6. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.31.101.0/255.255.255.0
Device	Site_1_D
Distance (Advanced)	4

To configure security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and then select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_1_A
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

3. Select **Create New**.
4. Enter the following information, and select **OK**:

Incoming Interface	Site_1_A
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

5. Select **Create New**.
6. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_1_B
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

7. Select **Create New**.
8. Enter the following information, and select **OK**:

Incoming Interface	Site_1_B
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

9. Select **Create New**.
10. Enter the following information, and select **OK**:

Incoming Interface	Internal

Source Address	All
Outgoing Interface	Site_1_C
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

11. Select **Create New**.
12. Enter the following information, and select **OK**:

Incoming Interface	Site_1_C
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

13. Select **Create New**.
14. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_1_D
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

15. Select **Create New**.
16. Enter the following information, and select **OK**:

Incoming Interface	Site_1_D
Source Address	All

Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

Configuring FortiGate_2

The configuration for FortiGate_2 is very similar to that of FortiGate_1. You must:

- Configure the interfaces involved in the VPN.
- Define the Phase 1 configuration for each of the four possible paths, creating a virtual IPsec interface for each one.
- Define the Phase 2 configuration for each of the four possible paths.
- Configure routes for the four IPsec interfaces, assigning the appropriate priorities.
- Configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces.

To configure the network interfaces

1. Go to **System > Network > Interfaces**.
2. Select the Internal interface and then select **Edit**. Enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`10.31.101.0/255.255.255.0`

3. Select the WAN1 interface and then select **Edit**. Enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`192.168.20.2/255.255.255.0`

4. Select the WAN2 interface and then select **Edit**. Enter the following information and then select **OK**:

Addressing mode	Manual
IP/Netmask	`172.16.30.2/255.255.255.0`

To configure the IPsec interfaces (Phase 1 configurations)

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**:

Name	`Site_2_A`

Remote Gateway	Static IP Address
IP Address	`192.168.10.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

4. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_2_B`
Remote Gateway	Static IP Address
IP Address	`172.16.20.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

5. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_2_C`
Remote Gateway	Static IP Address
IP Address	`192.168.10.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key

Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

6. Create a new tunnel and enter the following Phase 1 information:

Name	`Site_2_D`
Remote Gateway	Static IP Address
IP Address	`172.16.20.2`
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

To define the Phase 2 configurations for the four VPNs

1. On the first VPN route, open the **Phase 2 Selectors** panel.
2. Enter the following information and select **OK**:

Name	`Route_A`
Phase 1	`Site_2_A`

3. Enter the following Phase 2 information for the subsequent route:

Name	`Route_B`
Phase 1	`Site_2_B`

4. Enter the following Phase 2 information for the subsequent route:

Name	`Route_C`
Phase 1	`Site_2_C`

5. Enter the following Phase 2 information for the subsequent route:

Name	Route_D
Phase 1	Site_2_D

To configure routes

1. Go to **Router > Static > Static Routes**.

   For low-end FortiGate units, go to **System > Network > Routing**.
2. Select **Create New**, enter the following default gateway information and then select **OK**:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	WAN1
Gateway	192.168.10.1
Distance (Advanced)	10

3. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_A
Distance (Advanced)	1

4. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_B
Distance (Advanced)	2

5. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_C
Distance (Advanced)	3

6. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	10.21.101.0/255.255.255.0
Device	Site_2_D
Distance (Advanced)	4

To configure security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_A
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

3. Select **Create New**.
4. Enter the following information, and select **OK**:

Incoming Interface	Site_2_A
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

5. Select **Create New**.
6. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_B
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

7. Select **Create New**.
8. Enter the following information, and select **OK**:

Incoming Interface	Site_2_B
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

9. Select **Create New**.
10. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_C
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

11. Select **Create New**.
12. Enter the following information, and select **OK**:

Incoming Interface	Site_2_C
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

13. Select **Create New**.
14. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_D
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

15. Select **Create New**.
16. Enter the following information, and select **OK**:

Incoming Interface	Site_2_D
Source Address	All
Outgoing Interface	Internal
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

Partially-redundant route-based VPN example

This example demonstrates how to set up a partially redundant IPsec VPN between a local FortiGate unit and a remote VPN peer that receives a dynamic IP address from an ISP before it connects to the FortiGate unit. For more information about FortiGate dialup-client configurations, see FortiGate dialup-client configurations on page 1669.

When a FortiGate unit has more than one interface to the Internet (see FortiGate_1), you can configure redundant routes. If the primary connection fails, the FortiGate unit can establish a VPN using the redundant connection.

In this case, FortiGate_2 has only one connection to the Internet. If the link to the ISP were to go down, the connection to FortiGate_1 would be lost, and the tunnel would be taken down. The tunnel is said to be partially redundant because FortiGate_2 does not support a redundant connection.

In the configuration example:

- Both FortiGate units operate in NAT mode.
- Two separate interfaces to the Internet (192.168.10.2 and 172.16.20.2) are available on FortiGate_1. Each interface has a static public IP address.
- FortiGate_2 has a single connection to the Internet and obtains a dynamic public IP address (for example, 172.16.30.1) when it connects to the Internet.

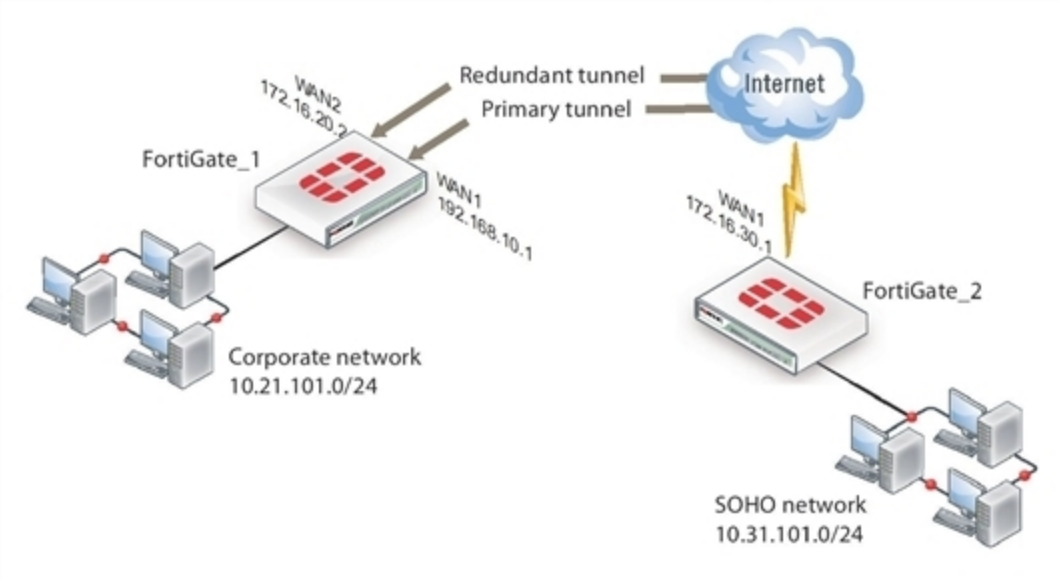
- FortiGate_2 forwards IP packets from the SOHO network (10.31.101.0/24) to the corporate network (10.21.101.0/24) behind FortiGate_1 through a partially redundant IPsec VPN. Encrypted packets from FortiGate_2 are addressed to the public interface of FortiGate_1. Encrypted packets from FortiGate_1 are addressed to the public IP address of FortiGate_2.

There are two possible paths for communication between the two units. In this example, these paths, listed in descending priority, are:

- FortiGate_1 WAN 1 to FortiGate_2 WAN 1
- FortiGate_1 WAN 2 to FortiGate_2 WAN 1

For each path, VPN configuration, security policies and routing are defined. By specifying a different routing distance for each path, the paths are prioritized. A VPN tunnel is established on each path, but only the highest priority one is used. If the highest priority path goes down, the traffic is automatically routed over the next highest priority path. You could use dynamic routing, but to keep this example simple, static routing is used.

Example partially redundant route-based configuration



Configuring FortiGate_1

Whenconfiguring FortiGate_1, you must:

- Configure the interfaces involved in the VPN.
- Define the Phase 1 configuration for each of the two possible paths, creating a virtual IPsec interface for each one.
- Define the Phase 2 configuration for each of the two possible paths.
- Configure incoming and outgoing security policies between the internal interface and each of the virtual IPsec interfaces.

To configure the network interfaces

1. Go to **System > Network > Interfaces**.
2. Select the Internal interface and select **Edit**. Enter the following information and select **OK**:

Addressing mode	Manual
IP/Netmask	10.21.101.2/255.255.255.0

3. Select the WAN1 interface and select **Edit**. Enter the following information and select **OK**:

Addressing mode	Manual
IP/Netmask	192.168.10.2/255.255.255.0

4. Select the WAN2 interface and select **Edit**. Enter the following information and select **OK**:

Addressing mode	Manual
IP/Netmask	172.16.20.2/255.255.255.0

To configure the IPsec interfaces (Phase 1 configurations)

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**:

Name	Site_1_A
Remote Gateway	Dialup User
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

4. Create a new tunnel and enter the following Phase 1 information:

Name	Site_1_B
Remote Gateway	Dialup User
Local Interface	WAN2
Mode	Main
Authentication Method	Preshared Key

Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

To define the Phase 2 configurations for the two VPNs

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and select **OK**:

Name	`Route_A`
Phase 1	`Site_1_A`

3. Enter the following Phase 2 information for the subsequent route:

Name	`Route_B`
Phase 1	`Site_1_B`

To configure routes

1. Go to **Router > Static > Static Routes**.
2. For low-end FortiGate units, go to **System > Network > Routing**.
3. Select **Create New**, enter the following default gateway information and select **OK**:

Destination IP/Mask	`0.0.0.0/0.0.0.0`
Device	WAN1
Gateway	`192.168.10.1`
Distance (Advanced)	10

To configure security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_1_A
Destination Address	All

Schedule	Always
Service	Any
Action	ACCEPT

3. Select **Create New**.
4. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_1_B
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

Configuring FortiGate_2

The configuration for FortiGate_2 is similar to that of FortiGate_1. You must

- configure the interface involved in the VPN
- define the Phase 1 configuration for the primary and redundant paths, creating a virtual IPsec interface for each one
- define the Phase 2 configurations for the primary and redundant paths, defining the internal network as the source address so that FortiGate_1 can automatically configure routing
- configure the routes for the two IPsec interfaces, assigning the appropriate priorities
- configure security policies between the internal interface and each of the virtual IPsec interfaces

To configure the network interfaces

1. Go to **System > Network > Interfaces**.
2. Select the Internal interface and select **Edit**. Enter the following information and select **OK**:

Addressing mode	Manual
IP/Netmask	`10.31.101.2/255.255.255.0`

3. Select the WAN1 interface and select **Edit**. Set the **Addressing mode** to **DHCP**.

To configure the two IPsec interfaces (Phase 1 configurations)

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).
3. Enter the following information, and select **OK**:

Name	Site_2_A
Remote Gateway	Static IP Address
IP Address	192.168.10.2
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

4. Create a new tunnel and enter the following Phase 1 information:

Name	Site_2_B
Remote Gateway	Static IP Address
IP Address	172.16.20.2
Local Interface	WAN1
Mode	Main
Authentication Method	Preshared Key
Pre-shared Key	Enter the preshared key.
Peer Options	Any peer ID
Advanced	
Dead Peer Detection	Select

To define the Phase 2 configurations for the two VPNs

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and select **OK**:

Name	Route_A
Phase 1	Site_2_A
Advanced	
Source Address	10.31.101.0/24

3. Enter the following Phase 2 information for the subsequent route:

Name	`Route_B`
Phase 1	`Site_2_B`
Advanced	
Source Address	10.31.101.0/24

To configure routes

1. Go to **Router > Static > Static Routes**.

   For low-end FortiGate units, go to **System > Network > Routing**.
2. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	`10.21.101.0/255.255.255.0`
Device	Site_2_A
Distance (Advanced)	1

3. Select **Create New**, enter the following information and then select **OK**:

Destination IP/Mask	`10.21.101.0/255.255.255.0`
Device	Site_2_B
Distance (Advanced)	2

To configure security policies

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_A
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

3. Select **Create New**.
4. Enter the following information, and select **OK**:

Incoming Interface	Internal
Source Address	All
Outgoing Interface	Site_2_B
Destination Address	All
Schedule	Always
Service	Any
Action	ACCEPT

Creating a backup IPsec interface

You can configure a route-based VPN that acts as a backup facility to another VPN. It is used only while your main VPN is out of service. This is desirable when the redundant VPN uses a more expensive facility.

You can configure a backup IPsec interface only in the CLI. The backup feature works only on interfaces with static addresses that have dead peer detection enabled. The `monitor` option creates a backup VPN for the specified Phase 1 configuration.

In the following example, backup_vpn is a backup for main_vpn.

```
config vpn ipsec phase1-interface
   edit main_vpn
      set dpd on
      set interface port1
      set nattraversal enable
      set psksecret "hard-to-guess"
      set remote-gw 192.168.10.8
      set type static
   end
   edit backup_vpn
      set dpd on
      set interface port2
      set monitor main_vpn
      set nattraversal enable
      set psksecret "hard-to-guess"
      set remote-gw 192.168.10.8
      set type static
   end
```

Transparent mode VPNs

This section describes transparent VPN configurations, in which two FortiGate units create a VPN tunnel between two separate private networks transparently.

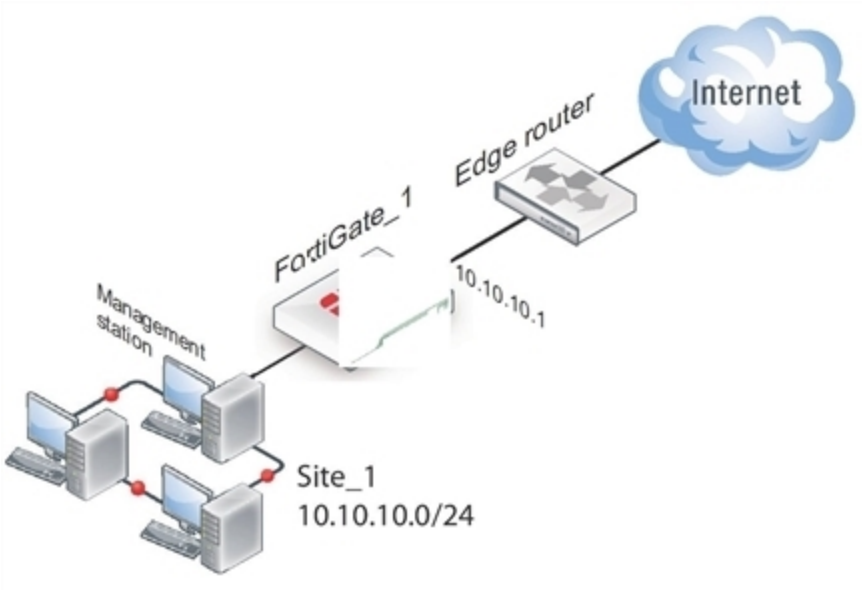
The following topics are included in this section:

Configuration overview
Configure the VPN peers

Configuration overview

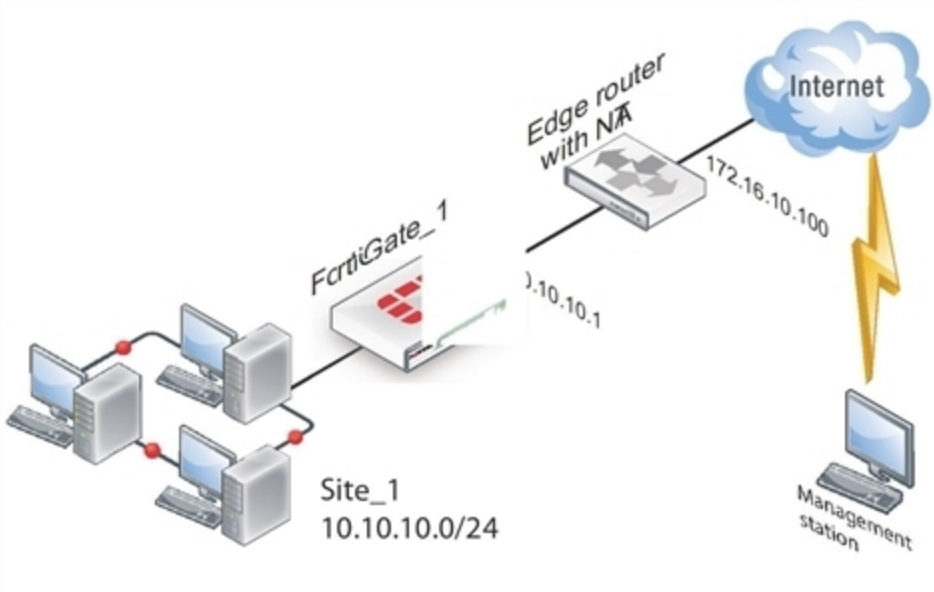
In transparent mode, all interfaces of the FortiGate unit except the management interface (which by default is assigned IP address 10.10.10.1/255.255.255.0) are invisible at the network layer. Typically, when a FortiGate unit runs in transparent mode, different network segments are connected to the FortiGate interfaces. The figure belows the management station on the same subnet. The management station can connect to the FortiGate unit directly through the web-based manager.

Management station on internal network



An edge router typically provides a public connection to the Internet and one interface of the FortiGate unit is connected to the router. If the FortiGate unit is managed from an external address (see the figure below), the router must translate (NAT) a routable address to direct management traffic to the FortiGate management interface.

Management station on external network



In a transparent VPN configuration, two FortiGate units create a VPN tunnel between two separate private networks transparently. All traffic between the two networks is encrypted and protected by FortiGate security policies.

Both FortiGate units may be running in transparent mode, or one could be running in transparent mode and the other running in NAT mode. If the remote peer is running in NAT mode, it must have a static public IP address.

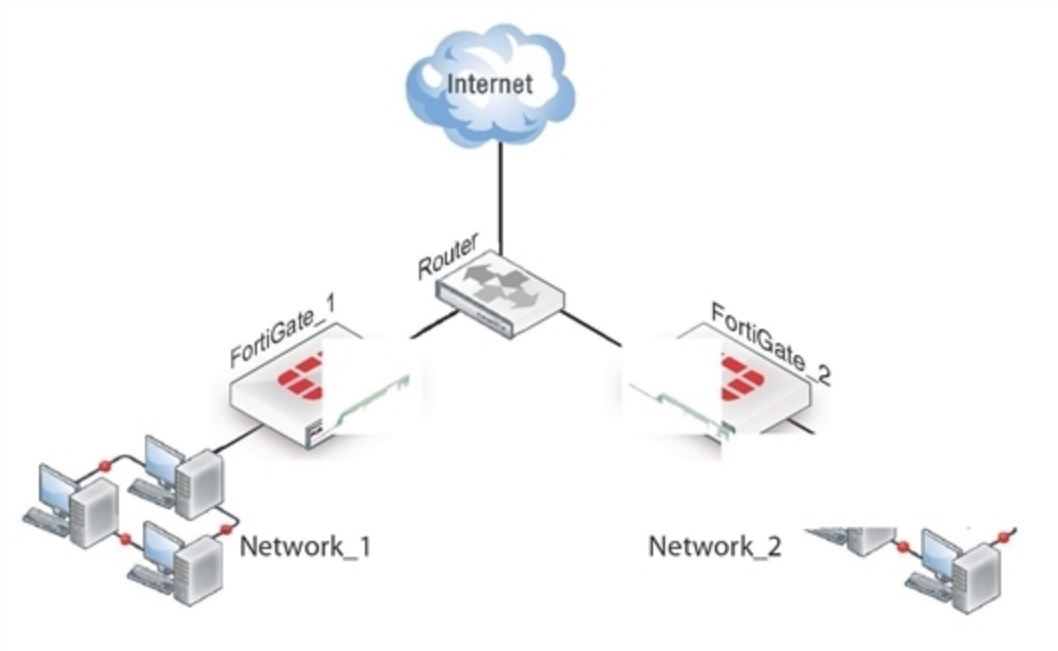
VPNs between two FortiGate units running in transparent mode do not support inbound/outbound NAT (supported through CLI commands) within the tunnel. In addition, a FortiGate unit running in transparent mode cannot be used in a hub-and-spoke configuration.

Encrypted packets from the remote VPN peer are addressed to the management interface of the local FortiGate unit. If the local FortiGate unit can reach the VPN peer locally, a static route to the VPN peer must be added to the routing table on the local FortiGate unit. If the VPN peer connects through the Internet, encrypted packets from the local FortiGate unit must be routed to the edge router instead. For information about how to add a static route to the FortiGate routing table, see the Advanced Routing Guide.

In the example configuration shown above, Network Address Translation (NAT) is enabled on the router. When an encrypted packet from the remote VPN peer arrives at the router through the Internet, the router performs inbound NAT and forwards the packet to the FortiGate unit. Refer to the software supplier's documentation to configure the router.

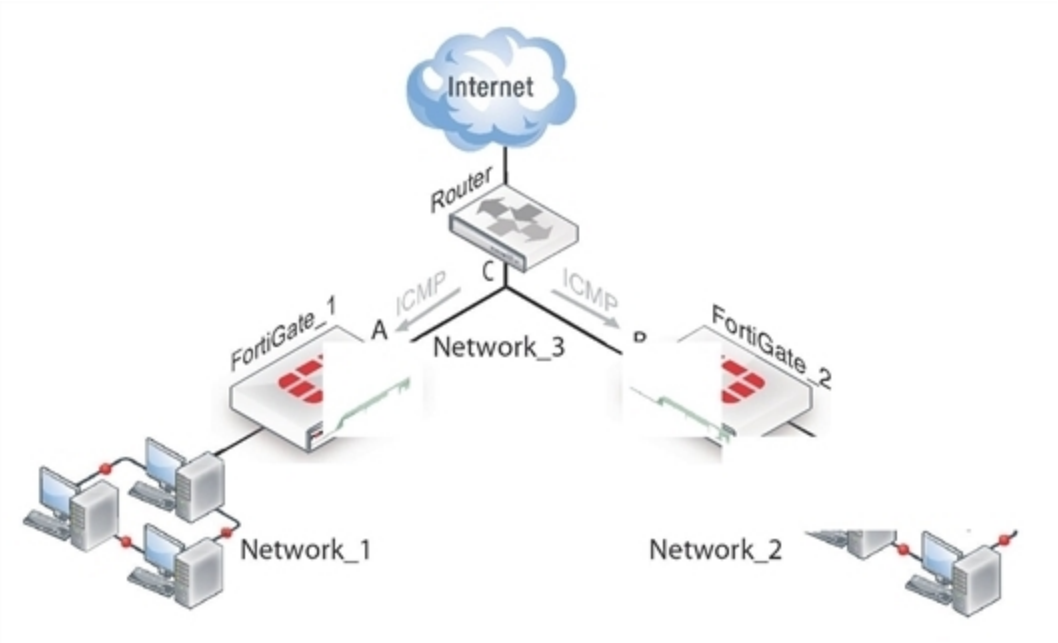
If you want to configure a VPN between two FortiGate units running in transparent mode, each unit must have an independent connection to a router that acts as a gateway to the Internet, and both units must be on separate networks that have a different address space. When the two networks linked by the VPN tunnel have different address spaces (see the figure below), at least one router must separate the two FortiGate units, unless the packets can be redirected using ICMP (as shown in the following figure).

Link between two FortiGate units in transparent mode



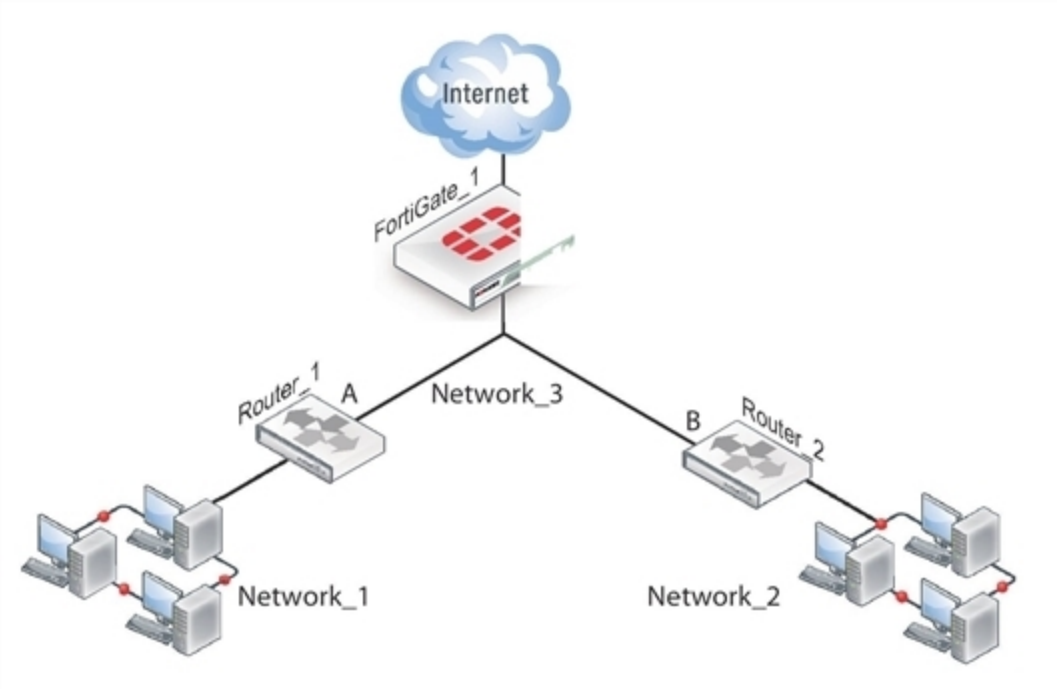
In the figure below, interface C behind the router is the default gateway for both FortiGate units. Packets that cannot be delivered on Network_1 are routed to interface C by default. Similarly, packets that cannot be delivered on Network_2 are routed to interface C. In this case, the router must be configured to redirect packets destined for Network_1 to interface A and redirect packets destined for Network_2 to interface B.

ICMP redirecting packets to two FortiGate units in transparent mode



If there are additional routers behind the FortiGate unit (see the figure below) and the destination IP address of an inbound packet is on a network behind one of those routers, the FortiGate routing table must include routes to those networks. For example, in the following figure, the FortiGate unit must be configured with static routes to interfaces A and B in order to forward packets to Network_1 and Network_2 respectively.

Destinations on remote networks behind internal routers



Transparent VPN infrastructure requirements

- The local FortiGate unit must be operating in transparent mode.
- The management IP address of the local FortiGate unit specifies the local VPN gateway. The management IP address is considered a static IP address for the local VPN peer.
- If the local FortiGate unit is managed through the Internet, or if the VPN peer connects through the Internet, the edge router must be configured to perform inbound NAT and forward management traffic and/or encrypted packets to the FortiGate unit.
- If the remote peer is operating in NAT mode, it must have a static public IP address.

A FortiGate unit operating in transparent mode requires the following basic configuration to operate as a node on the IP network:

- The unit must have sufficient routing information to reach the management station.
- For any traffic to reach external destinations, a default static route to an edge router that forwards packets to the Internet must be present in the FortiGate routing table.
- When all of the destinations are located on the external network, the FortiGate unit may route packets using a single default static route. If the network topology is more complex, one or more static routes in addition to the default static route may be required in the FortiGate routing table.

Only policy-based VPN configurations are possible in transparent mode.

Before you begin

An IPsec VPN definition links a gateway with a tunnel and an IPsec policy. If your network topology includes more than one virtual domain, you must choose components that were created in the same virtual domain. Therefore, before you define a transparent VPN configuration, choose an appropriate virtual domain in which to create the required interfaces, security policies, and VPN components. For more information, see the Virtual Domains guide.

Configure the VPN peers

1. The local VPN peer need to operate in transparent mode.
   To determine if your FortiGate unit is in transparent mode, go to **System > Dashboard > Status** to the **System Information** widget. Select **[change]**. Select transparent for the **Operation Mode**. Two new fields will appear to enter the **Management IP/Netmask**, and the **Default Gateway**.
   In transparent mode, the FortiGate unit is invisible to the network. All of its interfaces are on the same subnet and share the same IP address. You only have to configure a management IP address so that you can make configuration changes.

   The remote VPN peer may operate in NAT mode or transparent mode.
2. At the local FortiGate unit, define the Phase 1 parameters needed to establish a secure connection with the remote peer. See Phase 1 parameters on page 1581. Select **Advanced** and enter these settings in particular:

Remote Gateway	Select **Static IP Address**.
IP Address	Type the IP address of the public interface to the remote peer. If the remote peer is a FortiGate unit running in transparent mode, type the IP address of the remote management interface.
Advanced	Select **Nat-traversal**, and type a value into the **Keepalive Frequency** field. These settings protect the headers of encrypted packets from being altered by external NAT devices and ensure that NAT address mappings do not change while the VPN tunnel is open. For more information, see Phase 1 parameters on page 1581 and Phase 1 parameters on page 1581.

3. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. See Phase 2 parameters on page 1598. Select the set of Phase 1 parameters that you defined for the remote peer. The name of the remote peer can be selected from the **Static IP Address** list.
4. Define the source and destination addresses of the IP packets that are to be transported through the VPN tunnel. See Defining VPN security policies on page 1603. Enter these settings in particular:
   - For the originating address (source address), enter the IP address and netmask of the private network behind the local peer network. for the management interface, for example, `10.10.10.0/24`. This address needs to be a range to allow traffic from your network through the tunnel. Optionally select `any` for this address.
   - For the remote address (destination address), enter the IP address and netmask of the private network behind the remote peer (for example, `192.168.10.0/24`). If the remote peer is a FortiGate unit running in transparent mode, enter the IP address of the remote management interface instead.
5. Define an IPsec security policy to permit communications between the source and destination addresses. See Defining VPN security policies on page 1603. Enter these settings in particular:

Incoming Interface	Select the local interface to the internal (private) network.
Source Address	Select the source address that you defined in Step 4.
Outgoing Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Destination Address	Select the destination address that you defined in Step 4.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

6. Place the policy in the policy list above any other policies having similar source and destination addresses.
7. Define another IPsec security policy to permit communications between the source and destination addresses in the opposite direction. This security policy and the previous one form a bi-directional policy pair. See Defining VPN security policies on page 1603. Enter these settings in particular:

Incoming Interface	Select the interface to the edge router. When you configure the IPsec security policy on a remote peer that operates in NAT mode, you select the public interface to the external (public) network instead.
Source Address	Select the destination address that you defined in Step 4..
Outgoing Interface	Select the local interface to the internal (private) network.
Destination Address	Select the source address that you defined in Step 4.
VPN Tunnel	Select **Use Existing** and select the name of the Phase 2 tunnel configuration that you created in Step 3 from the drop-down list. Select **Allow traffic to be initiated from the remote site** to enable traffic from the remote network to initiate the tunnel.

8. Repeat this procedure at the remote FortiGate unit to create bidirectional security policies. Use the local interface and address information local to the remote FortiGate unit.

For more information on transparent mode, see the System Administration Guide.

IPv6 IPsec VPNs

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations to not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Admin > Settings**.
2. In the **Display Options on GUI** section, select **IPv6**.
3. Select **Apply**.

The following topics are included in this section:

Overview of IPv6 IPsec support
Configuring IPv6 IPsec VPNs
Site-to-site IPv6 over IPv6 VPN example
Site-to-site IPv4 over IPv6 VPN example
Site-to-site IPv6 over IPv4 VPN example

Certificates

On a VPN with IPv6 Phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support. FortiOS 5.2 is IPv6 Ready Logo Program Phase 2 certified.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The Phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The Phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 Phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: Phase 1 settings, Phase 2 settings, security policies and routing.

By default IPv6 configurations to not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Admin > Settings**.
2. In the **Display Options on GUI** section, select **IPv6**.
3. Select **Apply**.

Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec Phase 1 configuration as IPv6 by setting `ip-version` to `6`. Its default value is `4`. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
   edit tunnel6
      set ip-version 6
      set remote-gw6 0:123:4567::1234
      set interface port3
      set proposal 3des-md5
   end
```

Phase 2 configuration

To create an IPv6 IPsec Phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges, or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “::/0” for the `subnet6` address type, for example. The simplest IPv6 Phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
   edit tunnel6_p2
```

```
        set phase1name tunnel6
        set proposal 3des-md5
        set src-addr-type subnet6
        set dst-addr-type subnet6
    end
```

The management of static selector rules is performed by the IKE daemon, which allows named selectors to be reloaded if any named address or address groups are changed, without requiring the FortiGate unit to be rebooted before applying changes.

Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route in the web-based manager

1. Go to **Router > Static > Static Routes**.
   On low-end FortiGate units, go to **System > Network > Routing**.
2. Select the drop-down arrow on the **Create New** button and select **IPv6 Route**.
3. Enter the information and select **OK**.

In the CLI, use the `router static6` command. For example, where the remote network is fec0:0000:0000:0004::/64 and the IPsec interface is `toB`:

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   next
end
```

If the VPN is IPV4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

Site-to-site IPv6 over IPv6 VPN example

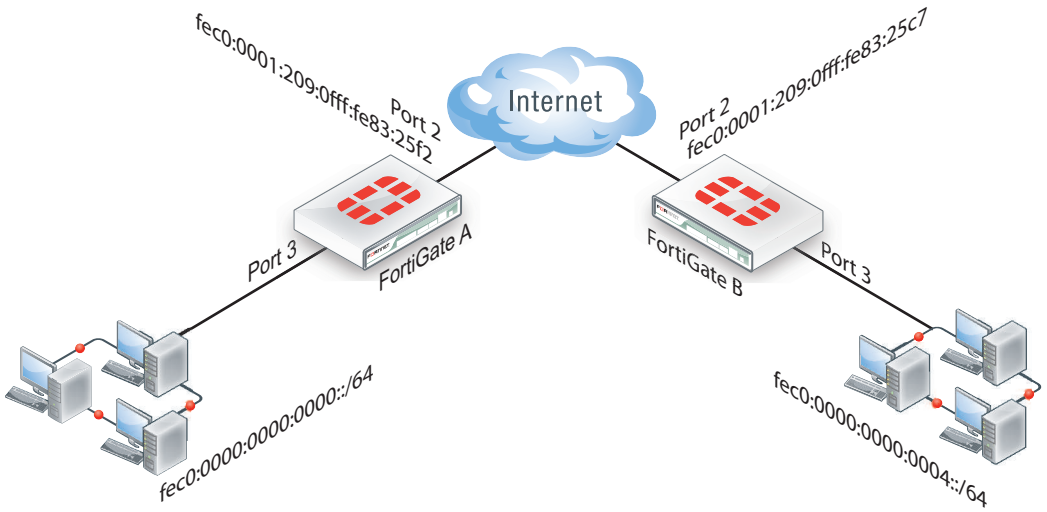
In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

By default IPv6 configurations to not appear on the Web-based Manager. You need to enable the feature first.

To enable IPv6

1. Go to **System > Admin > Settings**.
2. In the **Display Options on GUI** section, select **IPv6**.
3. Select **Apply**.

Example IPv6-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0000:209:0fff:fe83:25f3/64
      end
   next
end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
```

```
   edit toB
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
```

```
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

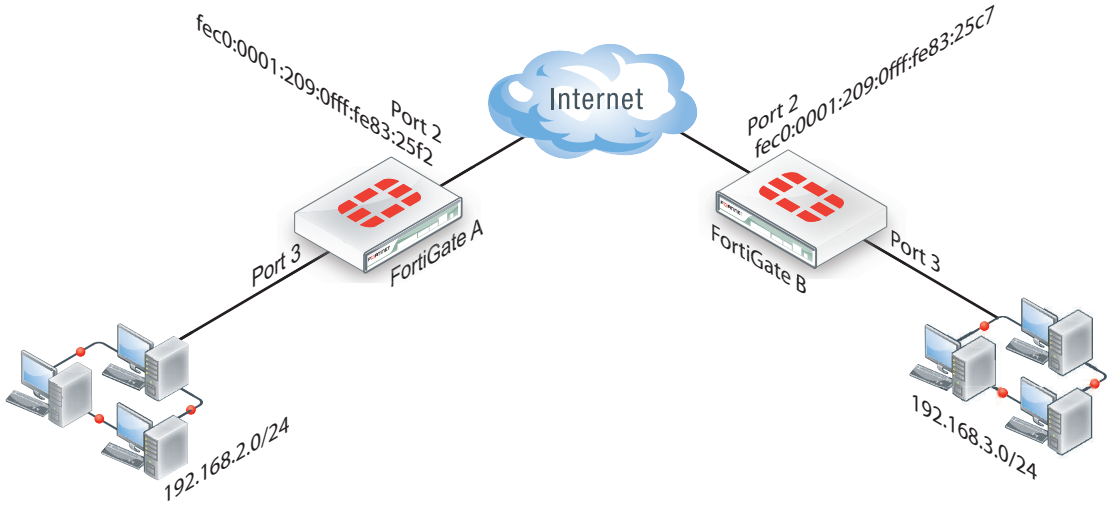
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:209:0fff:fe83:25c7/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
```

```
      set schedule always
   end
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      set 192.168.2.1/24
   end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
   edit toB
      set ip-version 6
```

```
      set interface port2
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The Phase 2 configuration is the same as you would use for an IPv4 VPN. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst 192.168.3.0/24
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

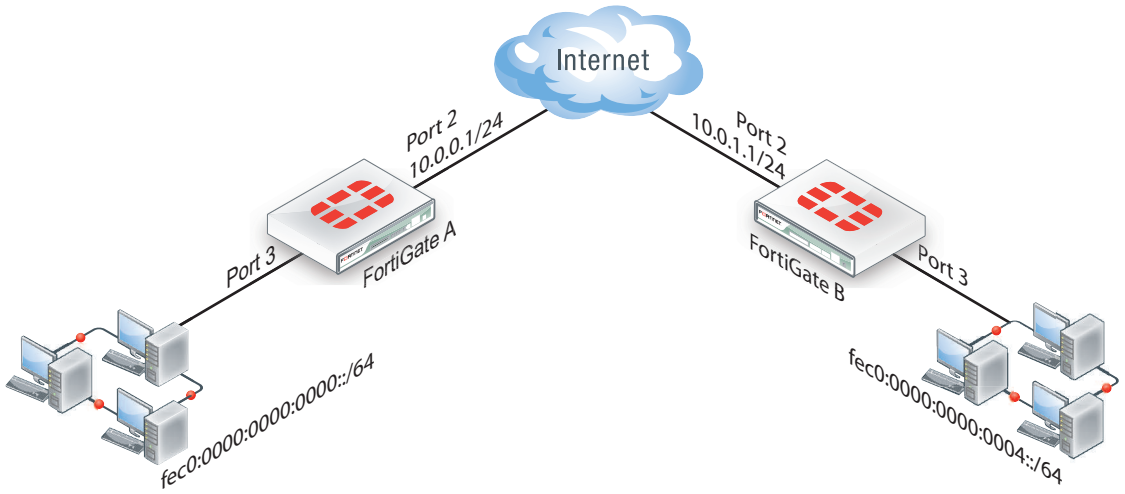
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:fe83:25c7/64
      end
   next
   edit port3
      set 192.168.3.1/24
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device port2
```

```
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst 192.168.2.0/24
   end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
   edit port2
      set 10.0.0.1/24
      next
      edit port3
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f3/64
      end
```

Configure FortiGate A IPsec settings

The Phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
   edit toB
      set interface port2
      set remote-gw 10.0.1.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The Phase 2 configuration uses IPv6 selectors. By default, Phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
      edit 1
         set device toB
         set dst fec0:0000:0000:0004::/64
      end
   config router static
      edit 1
         set device port2
         set dst 0.0.0.0/0
         set gateway 10.0.0.254
      end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec Phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
   edit port2
      set 10.0.1.1/24
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
config vpn ipsec phase1-interface
   edit toA
      set interface port2
      set remote-gw 10.0.0.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device toA
```

```
      set dst fec0:0000:0000:0000::/64
   end
config router static
   edit 1
      set device port2
      set gateway 10.0.1.254
   end
```

L2TP and IPsec (Microsoft VPN)

This section describes how to set up a VPN that is compatible with the Microsoft Windows native VPN, which is Layer 2 Tunneling Protocol (L2TP) with IPsec encryption.

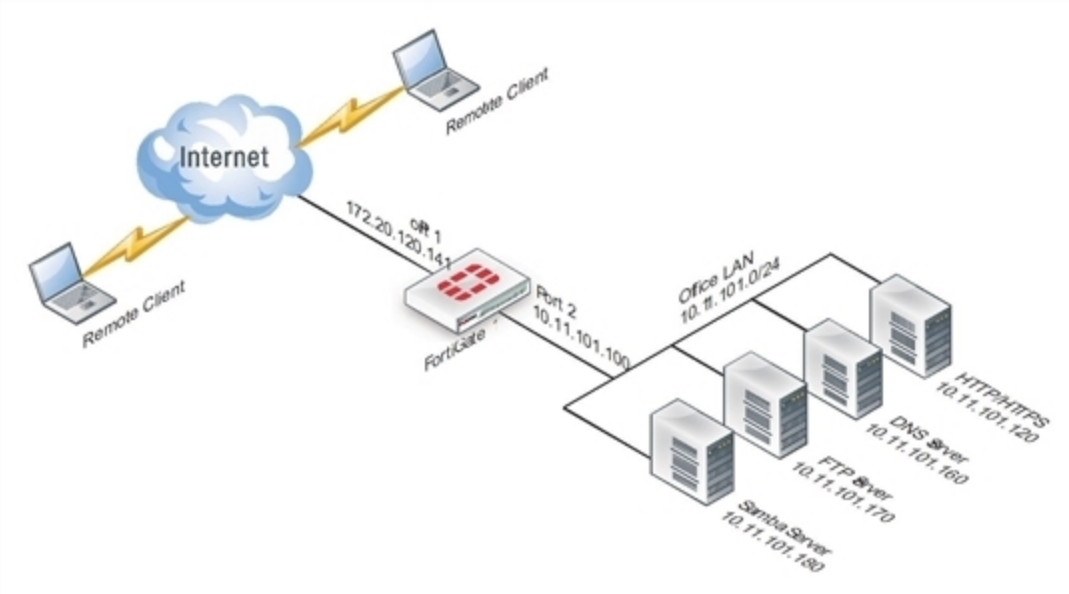
The following topics are included in this section:

Overview
Assumptions
Configuring the FortiGate unit
Configuring the Windows PC
Troubleshooting

Overview

The topology of a VPN for Microsoft Windows dialup clients is very similar to the topology for FortiClient Endpoint Security clients.

Example FortiGate VPN configuration with Microsoft clients



For users, the difference is that instead of installing and using the FortiClient application, they configure a network connection using the software built into the Microsoft Windows operating system. FortiOS 5.2 can configure a FortiGate unit to work with unmodified Microsoft VPN client software.

Layer 2 Tunneling Protocol (L2TP)

L2TP is a tunneling protocol published in 1999 that is used with VPNs, as the name suggests. Microsoft Windows operating system has a built-in L2TP client starting since Windows 2000. Mac OS X 10.3 system and higher also have a built-in client.

L2TP provides no encryption and used UDP port 1701. IPsec is used to secure L2TP packets. The initiator of the L2TP tunnel is called the L2TP Access Concentrator (LAC).

L2TP and IPsec is supported for native Windows XP, Windows Vista and Mac OSX native VPN clients. However, in Mac OSX (OSX 10.6.3, including patch releases) the L2TP feature does not work properly on the Mac OS side.

Assumptions

The following assumptions have been made for this example:

- L2TP protocol traffic is allowed through network firewalls (TCP and UDP port 1701)
- User has Microsoft Windows 2000 or higher — a Windows version that supports L2TP

Configuring the FortiGate unit

To configure the FortiGate unit, you must:

- Configure LT2P users and firewall user group.
- Configure the L2TP VPN, including the IP address range it assigns to clients.
- Configure an IPsec VPN with encryption and authentication settings that match the Microsoft VPN client.
- Configure security policies.

Configuring LT2P users and firewall user group

Remote users must be authenticated before they can request services and/or access network resources through the VPN. The authentication process can use a password defined on the FortiGate unit or an established external authentication mechanism such as RADIUS or LDAP.

Creating user accounts

You need to create user accounts and then add these users to a firewall user group to be used for L2TP authentication. The Microsoft VPN client can automatically send the user's Window network logon credentials. You might want to use these for their L2TP user name and password.

To create a user account - web-based manager

1. Go to **User & Device > User > User Definition** and select **Create New**.
2. Enter the **User Name**.
3. Do one of the following:
   - Select **Password** and enter the user's assigned password.
   - Select **Match user on LDAP server**, **Match user on RADIUS server**, or **Match user onTACACS+ server** and select the authentication server from the list. The authentication server must be already configured on the FortiGate unit.
4. Select **OK**.

To create a user account - CLI

To create a user account called `user1` with the password `123_user`, enter:

```
config user local
   edit user1
      set type password
```

```
      set passwd "123_user"
      set status enable
   end
```

Creating a user group

When clients connect using the L2TP-over-IPsec VPN, the FortiGate unit checks their credentials against the user group you specify for L2TP authentication. You need to create a firewall user group to use for this purpose.

To create a user group - web-based manager

1. Go to **User & Device > User > User Groups**, select **Create New**, and enter the following:

Name	Type or edit the user group name (for example, `L2TP_group`).
Type	Select **Firewall**.
Available Users/Groups	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that can be added to the user group. To add a member to this list, select the name and then select the right arrow button.
Members	The list of Local users, RADIUS servers, LDAP servers, TACACS+ servers, or PKI users that belong to the user group. To remove a member, select the name and then select the left arrow button.

2. Select **OK**.

To create a user group - CLI

To create the user group L2TP_group and add members User_1, User_2, and User_3, enter:

```
config user group
   edit L2TP_group
      set group-type firewall
      set member User_1 User_2 User_3
   end
```

Configuring L2TP

You can only configure L2TP settings in the CLI. As well as enabling L2TP, you set the range of IP address values that are assigned to L2TP clients and specify the user group that can access the VPN. For example, to allow access to users in the L2TP_group and assign them addresses in the range 192.168.0.50 to 192.168.0.59, enter:

```
config vpn l2tp
   set sip 192.168.0.50
   set eip 192.168.0.59
   set status enable
   set usrgrp "L2TP_group"
end
```

One of the security policies for the L2TP over IPsec VPN uses the client address range, so you need also need to create a firewall address for that range. For example,

```
config firewall address
   edit L2TPclients
      set type iprange
```

```
        set start-ip 192.168.0.50
        set end-ip 192.168.0.59
    end
```

Alternatively, you could define this range in the web-based manager.

Configuring IPsec

The Microsoft VPN client uses IPsec for encryption. The configuration needed on the FortiGate unit is the same as for any other IPsec VPN with the following exceptions.

- Transport mode is used instead of tunnel mode.
- The encryption and authentication proposals must be compatible with the Microsoft client.

L2TP over IPsec is supported on the FortiGate unit using policy-based, not route-based configurations.

When configuring L2TP, do not name the VPN as "L2TP" as that will result in a conflict.

Configuring Phase 1 - web-based manager

1. Go to **VPN > IPsec > Tunnels** and create the new custom tunnel or edit an existing tunnel.
2. Edit the **Phase 1 Proposal** (if it is not available, you may need to click the **Convert to Custom Tunnel** button).

Name	Enter a name for this VPN, dialup_p1 for example.
Remote Gateway	**Dialup User**
Local Interface	Select the network interface that connects to the Internet. For example, port1.
Mode	**Main (ID protection)**
Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. This key must also be entered in the Microsoft VPN client.
Advanced	Select **Advanced** to enter the following information.
Phase 1 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Diffie-Hellman Group	2
NAT Traversal	Enable
Dead Peer Detection	Enable

Configuring Phase 1 - CLI

To create a Phase 1 configuration called dialup_p1 on a FortiGate unit that has port1 connected to the Internet, you would enter:

```
config vpn ipsec phase1
   edit dialup_p1
      set type dynamic
      set interface port1
      set mode main
      set psksecret ********
      set proposal aes256-md5 3des-sha1 aes192-sha1
      set dhgrp 2
      set nattraversal enable
      set dpd enable
end
```

Configuring Phase 2 - web-based manager

1. Open the **Phase 2 Selectors** panel.
2. Enter the following information and then select **OK**.

Phase 2 Proposal	Enter the following Encryption/Authentication pairs: AES256-MD5, 3DES-SHA1, AES192-SHA1
Enable replay detection	Enable
Enable perfect forward secrecy (PFS)	Disable
Keylife	3600 seconds

3. Make this a transport-mode VPN. You must use the CLI to do this. If your Phase 2 name is dialup_p2, you would enter:

```
config vpn ipsec phase2
   edit dialup_p2
      set encapsulation transport-mode
   end
```

Configuring Phase 2 - CLI

To configure a Phase 2 to work with your phase_1 configuration, you would enter:

```
config vpn ipsec phase2
   edit dialup_p2
      set phase1name dialup_p1
      set proposal aes256-md5 3des-sha1 aes192-sha1
      set replay enable
      set pfs disable
      set keylifeseconds 3600
      set encapsulation transport-mode
   end
```

Configuring security policies

The security policies required for L2TP over IPsec VPN are:

- An IPsec policy, as you would create for any policy-based IPsec VPN
- A regular ACCEPT policy to allow traffic from the L2TP clients to access the protected network

Configuring the IPsec security policy - web-based manager

1. Go to **System > Config > Features** and enable **Policy-based IPsec VPN**.
2. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
3. Set the **Action** to **IPsec** and enter the following information:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	All
Outgoing Interface	Select the FortiGate unit's public interface.
Destination Address	All
VPN Tunnel	Select **Use Existing** and select the name of the Phase 1 configuration that you created. For example, dialup_p1. See Configuring IPsec on page 1733.
Allow traffic to be initiated from the remote site	enable

4. Select **OK**.

Configuring the IPsec security policy - CLI

If your VPN tunnel (Phase 1) is called dialup_p1, your protected network is on port2, and your public interface is port1, you would enter:

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action ipsec
      set schedule always
      set service all
      set inbound enable
      set vpntunnel dialup_p1
   end
```

Configuring the ACCEPT security policy - web-based manager

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Leave the **Policy Type** as **Firewall** and leave the **Policy Subtype** as **Address**.
3. Enter the following information and select **OK**:

Incoming Interface	Select the FortiGate unit's public interface.
Source Address	Select the firewall address that you defined for the L2TP clients.
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	All
Action	ACCEPT

Configuring the ACCEPT security policy - CLI

If your public interface is port1, your protected network is on port2, and L2TPclients is the address range that L2TP clients use, you would enter:

```
config firewall policy
   edit 1
      set srcintf port1
      set dstintf port2
      set srcaddr L2TPclients
      set dstaddr all
      set action accept
      set schedule always
      set service all
   end
```

Configuring the Windows PC

Configuration of the Windows PC for a VPN connection to the FortiGate unit consists of the following:

1. In Network Connections, configure a Virtual Private Network connection to the FortiGate unit.
2. Ensure that the IPSEC service is running.
3. Ensure that IPsec has not been disabled for the VPN client. It may have been disabled to make the Microsoft VPN compatible with an earlier version of FortiOS.

The instructions in this section are based on Windows XP SP3. Other versions of Windows may vary slightly.

To configure the network connection

1. Open **Network Connections**.
   This is available through the Control Panel.
2. Double-click **New Connection Wizard** and **Select Next**.
3. Select **Connect to the network at my workplace**.
4. Select **Next**.
5. Select **Virtual Private Network connection** and select **Next**.
6. In the **Company Name** field, enter a name for the connection and select **Next**.
7. Select **Do not dial the initial connection** and then select **Next**.
8. Enter the public IP address or FQDN of the FortiGate unit and select **Next**.
9. Optionally, select **Add a shortcut to this connection to my desktop**.
10. Select **Finish**.
    The **Connect** dialog opens on the desktop.

11. Select **Properties** and then select the **Security** tab.
12. Select **IPsec Settings**.
13. Select **Use pre-shared key for authentication**, enter the preshared key that you configured for your VPN, and select **OK**.
14. Select **OK**.

To check that the IPSEC service is running

1. Open **Administrative Tools** through the Control Panel.
2. Double-click **Services**.
3. Look for IPSEC Services. Confirm that the **Startup Type** is **Automatic** and **Status** is set to **Started**. If needed, double-click **IPSEC Services** to change these settings.

To check that IPsec has not been disabled

1. Select **Start > Run**.
2. Enter regedit and select **OK**.
3. Find the Registry key HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\Parameters
4. If there is a ProhibitIPsec value, it must be set to 0.

Troubleshooting

This section describes some checks and tools you can use to resolve issues with L2TP-over-IPsec VPNs.

This section includes:

- Quick checks
- Mac OS X and L2TP
- Setting up logging
- Using the FortiGate unit debug commands

Quick checks

The table below is a list of common L2TP over IPsec VPN problems and the possible solutions.

Problem	What to check
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check the settings, including encapsulation setting, which must be transport-mode. Check the user password. Confirm that the user is a member of the user group assigned to L2TP. On the Windows PC, check that the IPsec service is running and has not been disabled. See Troubleshooting on page 1737.
Tunnel connects, but there is no communication.	Did you create an ACCEPT security policy from the public network to the protected network for the L2TP clients? See Troubleshooting on page 1737.

Mac OS X and L2TP

FortiOS allows L2TP connections with empty AVP host names and therefore Mac OS X L2TP connections can connect to the FortiGate.

Previously, FortiOS refused L2TP connections with empty AVP host names in compliance with RFC 2661 and RFC 3931.

Setting up logging

L2TP logging must be enabled to record L2TP events. Alert email can be configured to report L2TP errors.

To configure FortiGate logging for L2TP over IPsec

1. Go to **Log & Report > Log Config > Log Settings**.
2. Select **Event Log**.
3. Select the **VPN activity event** check box.
4. Select **Apply**.

To view FortiGate logs

1. Go to **Log & Report > Event Log > VPN**.
2. Select the **Log location** if required.
3. After each attempt to start the L2TP over IPsec VPN, select **Refresh** to view logged events.

Using the FortiGate unit debug commands

To view debug output for IKE and L2TP

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI commands

```
diagnose debug application ike -1
diagnose debug application l2tp -1
diagnose debug enable
```

3. Attempt to use the VPN and note the debug output in the SSH or Telnet session.
4. Enter the following command to reset debug settings to default:

```
diagnose debug reset
```

To use the packet sniffer

1. Start an SSH or Telnet session to your FortiGate unit.
2. Enter the following CLI command

```
diagnose sniffer packet any icmp 4
```

3. Attempt to use the VPN and note the debug output.
4. Enter `Ctrl-C` to end sniffer operation.

Typical L2TP over IPsec session startup log entries - raw format

GRE over IPsec (Cisco VPN)

This section describes how to configure a FortiGate VPN that is compatible with Cisco-style VPNs that use GRE in an IPsec tunnel.

The following topics are included in this section:

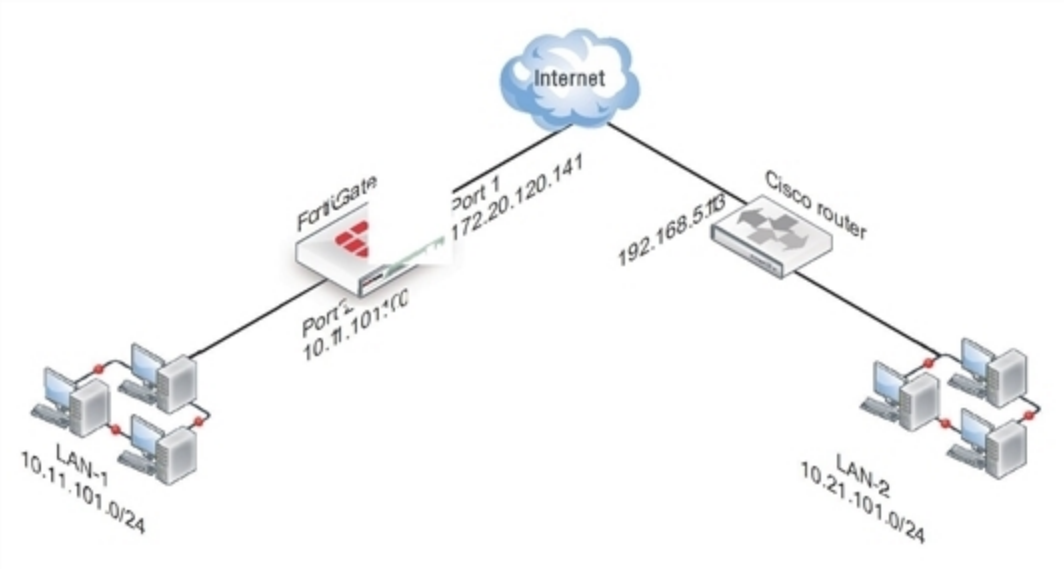
Overview
Configuring the FortiGate unit
Configuring the Cisco router
Troubleshooting

Overview

Cisco products that include VPN support often use Generic Routing Encapsulation (GRE) protocol tunnel over IPsec encryption. This chapter describes how to configure a FortiGate unit to work with this type of Cisco VPN.

Cisco VPNs can use either transport mode or tunnel mode IPsec. Previously, the FortiGate unit was compatible only with tunnel mode IPsec.

Example FortiGate to Cisco GRE-over-IPsec VPN



In this example, users on LAN-1 are provided access to LAN-2.

Configuring the FortiGate unit

There are several steps to the GRE-over-IPsec configuration:

- Enable overlapping subnets. This is needed because the IPsec and GRE tunnels will use the same addresses.
- Configure a route-based IPsec VPN on the external interface.
- Configure a GRE tunnel on the virtual IPsec interface. Set its local gateway and remote gateway addresses to match the local and remote gateways of the IPsec tunnel.

- Configure security policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Configure security policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.
- Configure a static route to direct traffic destined for the network behind the Cisco router into the GRE-over-IPsec tunnel.

Enabling overlapping subnets

By default, each FortiGate unit network interface must be on a separate network. The configuration described in this chapter assigns an IPsec tunnel end point and the external interface to the same network. Enable subnet overlap as follows:

```
config system settings
   set allow-subnet-overlap enable
end
```

Configuring the IPsec VPN

A route-based VPN is required. It must use encryption and authentication algorithms compatible with the Cisco equipment to which it connects. In this chapter, preshared key authentication is shown.

To configure the IPsec VPN - web-based manager

1. Define the Phase 1 configuration needed to establish a secure connection with the remote Cisco device. Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tocisco for example. This is the name of the virtual IPsec interface. It appears in Phase 2 configurations, security policies and the VPN monitor.
Remote Gateway	For example, 192.168.16.128.
IP Address	Enter the IP address of the Cisco device public interface. For example, 192.168.16.128.
Local Interface	Select the FortiGate unit's public interface. For example, 172.20.120.141.
Mode	Select **Main (ID Protection)**.
Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. It must match the preshared key on the Cisco device.
Advanced	Select the Advanced button to see the following settings.
Phase 1 Proposal	**3DES-MD5** At least one proposal must match the settings on the Cisco unit.

For more information about these settings, see Phase 1 parameters on page 1581.

2. Define the Phase 2 parameters needed to create a VPN tunnel with the remote peer. For compatibility with the Cisco router, Quick Mode Selectors must be entered, which includes specifying protocol 47, the GRE protocol. Enter these settings in particular:

Phase 2 Proposal	**3DES-MD5** At least one proposal must match the settings on the Cisco unit.
Quick Mode Selector	
Source Address	Enter the GRE local tunnel end IP address. For example 172.20.120.141.
Source Port	0
Destination Address	Enter the GRE remote tunnel end IP address. For example 192.168.16.128.
Destination Port	0
Protocol	47

   For more information about these settings, see Phase 2 parameters on page 1598.

3. If the Cisco device is configured to use transport mode IPsec, you need to use transport mode on the FortiGate VPN. You can configure this only in the CLI. In your Phase 2 configuration, set `encapsulation` to `transport-mode` as follows:

```
config vpn phase2-interface
   edit to_cisco_p2
      set encapsulation transport-mode
   end
```

To configure the IPsec VPN - CLI

```
config vpn ipsec phase1-interface
   edit tocisco
      set interface port1
      set proposal 3des-sha1 aes128-sha1
      set remote-gw 192.168.16.128
      set psksecret xxxxxxxxxxxxxxx
   end
config vpn ipsec phase2-interface
   edit tocisco_p2
      set phase1name "tocisco"
      set proposal 3des-md5
      set encapsulation tunnel-mode // if tunnel mode
      set encapsulation transport-mode // if transport mode
      set protocol 47
      set src-addr-type ip
      set dst-start-ip 192.168.16.128
      set src-start-ip 172.20.120.141
   end
```

Adding IPsec tunnel end addresses

The Cisco configuration requires an address for its end of the IPsec tunnel. The addresses are set to match the GRE gateway addresses. Use the CLI to set the addresses, like this:

```
config system interface
   edit tocisco
      set ip 172.137.0.1 255.255.255.255
      set remote-ip 172.128.0.1
   end
```

Configuring the GRE tunnel

The GRE tunnel runs between the virtual IPsec public interface on the FortiGate unit and the Cisco router. You must use the CLI to configure a GRE tunnel. In the example, you would enter:

```
config system gre-tunnel
   edit gre1
      set interface tocisco
      set local-gw 172.137.0.1
      set remote-gw 172.128.0.1
end
```

`interface` is the virtual IPsec interface, `local-gw` is the FortiGate unit public IP address, and `remote-gw` is the remote Cisco device public IP address

Adding GRE tunnel end addresses

You will also need to add tunnel end addresses. The Cisco router configuration requires an address for its end of the GRE tunnel. Using the CLI, enter tunnel end addresses that are not used elsewhere on the FortiGate unit, like this:

```
config system interface
   edit gre1
      set ip 10.0.1.1 255.255.255.255
      set remote-ip 10.0.1.2
   end
```

Configuring security policies

Two sets of security policies are required:

- Policies to allow traffic to pass in both directions between the GRE virtual interface and the IPsec virtual interface.
- Policies to allow traffic to pass in both directions between the protected network interface and the GRE virtual interface.

To configure security policies - web-based manager

1. Define an ACCEPT firewall security policy to permit communications between the protected network and the GRE tunnel:

Incoming Interface	Select the interface that connects to the private network behind this FortiGate unit.
Source Address	**All**

Outgoing Interface	Select the GRE tunnel virtual interface you configured.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

2. To permit the remote client to initiate communication, you need to define a firewall address security policy for communication in that direction:

Incoming Interface	Select the GRE tunnel virtual interface you configured.
Source Address	**All**
Outgoing Interface	Select the interface that connects to the private network behind this FortiGate unit.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

3. Define a pair of ACCEPT firewall address security policies to permit traffic to flow between the GRE virtual interface and the IPsec virtual interface:

Incoming Interface	Select the GRE virtual interface. See Configuring the GRE tunnel on page 1744.
Source Address	**All**
Outgoing Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 1742.
Destination Address	**All**
Action	**ACCEPT**
Enable NAT	Disable

Incoming Interface	Select the virtual IPsec interface you created. See Configuring the IPsec VPN on page 1742.
Source Address	**All**
Outgoing Interface	Select the GRE virtual interface.See Configuring the GRE tunnel on page 1744.
Destination Address	**All**

Action	**ACCEPT**
Enable NAT	Disable

To configure security policies - CLI

```
config firewall policy
   edit 1 // LAN to GRE tunnel
      set srcintf port2
      set dstintf gre1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 2 // GRE tunnel to LAN
      set srcintf gre1
      set dstintf port2
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
   next
   edit 3 // GRE tunnel to IPsec interface
      set srcintf "gre1"
      set dstintf "tocisco"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
   next
   edit 4 // IPsec interface to GRE tunnel
      set srcintf "tocisco"
      set dstintf "gre1"
      set srcaddr "all"
      set dstaddr "all"
      set action accept
      set schedule "always"
      set service "ANY"
   end
```

Configuring routing

Traffic destined for the network behind the Cisco router must be routed to the GRE tunnel. To do this, create a static route

1. Go to **Router > Static > Static Routes** and select **Create New**.

   For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.
2. Enter the following information and select **OK**.

Destination IP/Mask	Enter the IP address and netmask for the network behind the Cisco router. For example 10.21.101.0 255.255.255.0.
Device	Select the GRE virtual interface.
Distance (Advanced)	Leave setting at default value.

In the CLI, using the example values, you would enter

```
config router static
   edit 0
      set device gre1
      set dst 10.21.101.0 255.255.255.0
   end
```

Configuring the Cisco router

Using Cisco IOS, you would configure the Cisco router as follows, using the addresses from the example:

```
config ter
crypto ipsec transform-set myset esp-3des esp-md5-hmac
no mode
exit
no ip access-list extended tunnel
ip access-list extended tunnel
permit gre host 192.168.5.113 host 172.20.120.141
exit
interface Tunnel1
ip address 10.0.1.2 255.255.255.0
tunnel source 192.168.5.113
tunnel destination 172.20.120.141
!
ip route 10.11.101.0 255.255.255.0 Tunnel1
end
clea crypto sa
clea crypto isakmp
```

For transport mode, change `no mode` to `mode transport`.

This is only the portion of the Cisco router configuration that applies to the GRE-over-IPsec tunnel. For more information, refer to the Cisco documentation.

Troubleshooting

This section describes some checks and tools you can use to resolve issues with the GRE-over-IPsec VPN.

Quick checks

Here is a list of common problems and what to verify.

Problem	What to check
No communication with remote network.	Use the `execute ping` command to ping the Cisco device public interface. Use the FortiGate VPN Monitor page to see whether the IPsec tunnel is up or can be brought up.
IPsec tunnel does not come up.	Check the logs to determine whether the failure is in Phase 1 or Phase 2. Check that the encryption and authentication settings match those on the Cisco device. Check the encapsulation setting: tunnel-mode or transport-mode. Both devices must use the same mode.
Tunnel connects, but there is no communication.	Check the security policies. See Troubleshooting on page 1747. Check routing. See Troubleshooting on page 1747.

Setting up logging

To configure FortiGate logging for IPsec

1. Go to **Log & Report > Log Config > Log Settings**.
2. Select the **Event Logging**.
3. Select **VPN activity event**.
4. Select **Apply**.

To view FortiGate logs

1. Go to **Log & Report > Event Log > VPN**.
2. Select the log storage type.
3. Select **Refresh** to view any logged events.

GRE tunnel keepalives

In the event that each GRE tunnel endpoint has keepalive enabled, firewall policies allowing GRE are required in both directions. The policy should be configured as follows (where the IP addresses and interface names are for example purposes only):

```
config firewall policy
   edit < id >
      set srcintf "gre"
      set dstintf "port1"
      set srcaddr "1.1.1.1"
      set dstaddr "2.2.2.2"
      set action accept
      set schedule "always"
      set service "GRE"
   next
end
```

GRE tunnel with multicast traffic

If you want multicast traffic to traverse the GRE tunnel, you need to configure a multicast policy as well as enable multicast forwarding.

- To configure a multicast policy, use the `config firewall multicast-policy` command.
- To enable multicast forwarding, use the following commands:

```
config system settings
   set multicast-forward enable
end
```

Using diagnostic commands

There are some diagnostic commands that can provide useful information. When using diagnostic commands, it is best practice that you connect to the CLI using a terminal program, such as puTTY, that allows you to save output to a file. This will allow you to review the data later on at your own speed without worry about missed data as the diag output scrolls by.

To use the packet sniffer

1. Enter the following CLI command:
   ```
   diag sniff packet any icmp 4
   ```
2. Ping an address on the network behind the FortiGate unit from the network behind the Cisco router.

   The output will show packets coming in from the GRE interface going out of the interface that connects to the protected network (LAN) and vice versa. For example:
   ```
   114.124303 gre1 in 10.0.1.2 -> 10.11.101.10: icmp: echo request
   114.124367 port2 out 10.0.1.2 -> 10.11.101.10: icmp: echo request
   114.124466 port2 in 10.11.101.10 -> 10.0.1.2: icmp: echo reply
   114.124476 gre1 out 10.11.101.10 -> 10.0.1.2: icmp: echo reply
   ```
3. Enter `CTRL-C` to stop the sniffer.

To view debug output for IKE

1. Enter the following CLI commands
   ```
   diagnose debug application ike -1
   diagnose debug enable
   ```
2. Attempt to use the VPN or set up the VPN tunnel and note the debug output.
3. Enter CTRL-C to stop the debug output.
4. Enter the following command to reset debug settings to default:
   ```
   diagnose debug reset
   ```

Protecting OSPF with IPsec

For enhanced security, OSPF dynamic routing can be carried over IPsec VPN links.

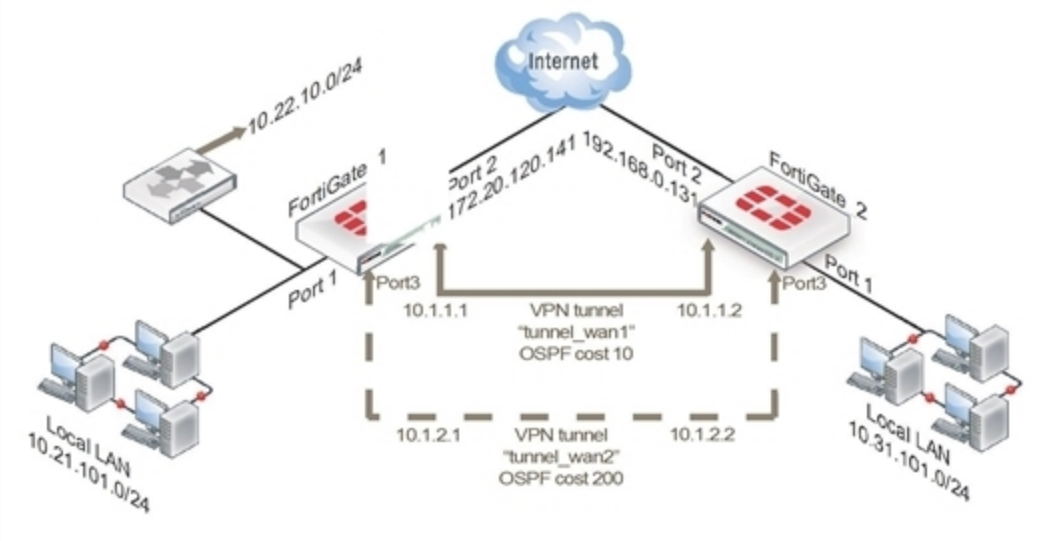
The following topics are included in this section:

Overview
OSPF over IPsec configuration
Creating a redundant configuration

Overview

This chapter shows an example of OSPF routing conducted over an IPsec tunnel between two FortiGate units. The network shown below is a single OSPF area. FortiGate_1 is an Area border router that advertises a static route to 10.22.10.0/24 in OSPF. FortiGate_2 advertises its local LAN as an OSPF internal route.

OSPF over an IPsec VPN tunnel



The section Overview describes the configuration with only one IPsec VPN tunnel, tunnel_wan1. Then, the section Overview describes how you can add a second tunnel to provide a redundant backup path. This is shown above as VPN tunnel “tunnel_wan2”.

Only the parts of the configuration concerned with creating the IPsec tunnel and integrating it into the OSPF network are described. It is assumed that security policies are already in place to allow traffic to flow between the interfaces on each FortiGate unit.

OSPF over IPsec configuration

There are several steps to the OSPF-over-IPsec configuration:

- Configure a route-based IPsec VPN on an external interface. It will connect to a corresponding interface on the other FortiGate unit. Define the two tunnel-end addresses.
- Configure a static route to the other FortiGate unit.

- Configure the tunnel network as part of the OSPF network and define the virtual IPsec interface as an OSPF interface.

This section describes the configuration with only one VPN, tunnel_wan1. The other VPN is added in the section OSPF over IPsec configuration on page 1750.

Configuring the IPsec VPN

A route-based VPN is required. In this chapter, preshared key authentication is shown. Certificate authentication is also possible. Both FortiGate units need this configuration.

To configure Phase 1

1. Define the Phase 1 configuration needed to establish a secure connection with the other FortiGate unit. For more information, see Phase 1 parameters on page 1581.

   Enter these settings in particular:

Name	Enter a name to identify the VPN tunnel, tunnel_wan1 for example. This becomes the name of the virtual IPsec interface.
Remote Gateway	Select **Static IP Address**.
IP Address	Enter the IP address of the other FortiGate unit's public (Port 2) interface.
Local Interface	Select this FortiGate unit's public (Port 2) interface.
Mode	Select **Main (ID Protection)**.
Authentication Method	**Preshared Key**
Pre-shared Key	Enter the preshared key. It must match the preshared key on the other FortiGate unit.
Advanced	Select **Advanced**.

To assign the tunnel end IP addresses

1. Go to **System > Network > Interfaces**, select the virtual IPsec interface that you just created on Port 2 and select **Edit**.
2. In the **IP** and **Remote IP** fields, enter the following tunnel end addresses:

	FortiGate_1	FortiGate_2
IP	10.1.1.1	10.1.1.2
Remote_IP	10.1.1.2	10.1.1.1

These addresses are from a network that is not used for anything else.

To configure Phase 2

1. Enter a name to identify this Phase 2 configuration, twan1_p2, for example.
2. Select the name of the Phase 1 configuration that you defined in Step "OSPF over IPsec configuration" on page 1750, tunnel_wan1 for example.

Configuring static routing

You need to define the route for traffic leaving the external interface.

1. Go to **Router > Static > Static Route**s, select **Create New**.
   For low-end FortiGate units, go to **System > Network > Routing** and select **Create New**.
2. Enter the following information.

Destination IP/Mask	Leave as 0.0.0.0 0.0.0.0.
Device	Select the external interface.
Gateway	Enter the IP address of the next hop router.

Configuring OSPF

This section does not attempt to explain OSPF router configuration. It focusses on the integration of the IPsec tunnel into the OSPF network. This is accomplished by assigning the tunnel as an OSPF interface, creating an OSPF route to the other FortiGate unit.

This configuration uses loopback interfaces to ease OSPF troubleshooting. The OSPF router ID is set to the loopback interface address.The loopback interface ensures the router is always up. Even though technically the router ID doesn't have to match a valid IP address on the FortiGate unit, having an IP that matches the router ID makes troubleshooting a lot easier.

The two FortiGate units have slightly different configurations. FortiGate_1 is an AS border router that advertises its static default route. FortiGate_2 advertises its local LAN as an OSPF internal route.

Setting the router ID for each FortiGate unit to the lowest possible value is useful if you want the FortiGate units to be the designated router (DR) for their respective ASes. This is the router that broadcasts the updates for the AS.

Leaving the IP address on the OSPF interface at 0.0.0.0 indicates that all potential routes will be advertised, and it will not be limited to any specific subnet. For example if this IP address was 10.1.0.0, then only routes that match that subnet will be advertised through this interface in OSPF.

FortiGate_1 OSPF configuration

When configuring FortiGate_1 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.1, you would enter:

```
config system interface
   edit lback1
      set vdom root
         set ip 10.0.0.1 255.255.255.255
         set type loopback
   end
```

The loopback addresses and corresponding router IDs on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

To configure OSPF area, networks, and interfaces - web-based manager

1. On FortiGate_1, go to **Router > Dynamic > OSPF**.
   For low end FortiGate units, you first need to enable **Dynamic Routing** by going to **System > Admin > Settings**.
2. Enter the following information to define the router, area, and interface information.

Router ID	Enter `10.0.0.1`. Select **Apply** before entering the remaining information.
Advanced Options	
Redistribute	Select the **Connected** and **Static** check boxes. Use their default metric values.
Areas	Select **Create New**, enter the **Area** and **Type** and then select **OK**.
Area	0.0.0.0
Type	Regular
Interfaces	Enter a name for the OSPF interface, ospf_wan1 for example.
Name	
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the **IP/Netmask** of `10.1.1.0/255.255.255.0` and an **Area** of `0.0.0.0`.
5. For **Networks**, select **Create New**.
6. Enter the **IP/Netmask** of `10.0.0.1/255.255.255.0` and an **Area** of `0.0.0.0`.
7. Select **Apply**.

To configure OSPF area and interfaces - CLI

Your loopback interface is 10.0.0.1, your tunnel ends are on the 10.1.1.0/24 network, and your virtual IPsec interface is named `tunnel_wan1`. Enter the following CLI commands:

```
config router ospf
   set router-id 10.0.0.1
   config area
      edit 0.0.0.0
   end
   config network
      edit 4
         set prefix 10.1.1.0 255.255.255.0
      next
      edit 2
         set prefix 10.0.0.1 255.255.255.255
      end
   config ospf-interface
      edit ospf_wan1
         set cost 10
         set interface tunnel_wan1
         set network-type point-to-point
      end
   config redistribute connected
      set status enable
   end
   config redistribute static
      set status enable
   end
end
```

FortiGate_2 OSPF configuration

When configuring FortiGate_2 for OSPF, the loopback interface is created, and then you configure OSPF area networks and interfaces.

Configuring FortiGate_2 differs from FortiGate_1 in that three interfaces are defined instead of two. The third interface is the local LAN that will be advertised into OSPF.

With the exception of creating the loopback interface, OSPF for this example can all be configured in either the web-based manager or CLI.

To create the loopback interface

A loopback interface can be configured in the CLI only. For example, if the interface will have an IP address of 10.0.0.2, you would enter:

```
config system interface
   edit lback1
      set vdom root
      set ip 10.0.0.2 255.255.255.255
      set type loopback
   end
```

The loopback addresses on the two FortiGate units must be different. For example, set the FortiGate 1 loopback to 10.0.0.1 and the FortiGate 2 loopback to 10.0.0.2.

To configure OSPF area and interfaces - web-based manager

1. On FortiGate_2, go to **Router > Dynamic > OSPF**.

   For low end FortiGate units, you first need to enable **Dynamic Routing** by going to **System > Admin > Settings**.
2. Complete the following.

Router ID	10.0.0.2
Areas	Select **Create New**, enter the **Area** and **Type** and then select **OK**.
Area	0.0.0.0
Type	Regular
Interfaces	
Name	Enter a name for the OSPF interface, ospf_wan1 for example.
Interface	Select the virtual IPsec interface, tunnel_wan1.
IP	0.0.0.0

3. For **Networks**, select **Create New**.
4. Enter the following information for the loopback interface:

IP/Netmask	10.0.0.2/255.255.255.255
Area	0.0.0.0

5. For **Networks**, select **Create New**.
6. Enter the following information for the tunnel interface:

IP/Netmask	10.1.1.0/255.255.255.255
Area	0.0.0.0

7. For **Networks**, select **Create New**.
8. Enter the following information for the local LAN interface:

IP/Netmask	10.31.101.0/255.255.255.255
Area	0.0.0.0

9. Select **Apply**.

To configure OSPF area and interfaces - CLI

If for example, your loopback interface is 10.0.0.2, your tunnel ends are on the 10.1.1.0/24 network, your local LAN is 10.31.101.0/24, and your virtual IPsec interface is named tunnel_wan1, you would enter:

```
config router ospf
   set router-id 10.0.0.2
   config area
      edit 0.0.0.0
   end
   config network
      edit 1
         set prefix 10.1.1.0 255.255.255.0
      next
      edit 2
         set prefix 10.31.101.0 255.255.255.0
      next
      edit 2
         set prefix 10.0.0.2 255.255.255.255
      end
   config ospf-interface
      edit ospf_wan1
         set interface tunnel_wan1
         set network-type point-to-point
      end
end
```

Creating a redundant configuration

You can improve the reliability of the OSPF over IPsec configuration described in the previous section by adding a second IPsec tunnel to use if the default one goes down. Redundancy in this case is not controlled by the IPsec VPN configuration but by the OSPF routing protocol.

To do this you:

- Create a second route-based IPsec tunnel on a different interface and define tunnel end addresses for it.
- Add the tunnel network as part of the OSPF network and define the virtual IPsec interface as an additional OSPF interface.
- Set the OSPF cost for the added OSPF interface to be significantly higher than the cost of the default route.

Adding the second IPsec tunnel

The configuration is the same as in Creating a redundant configuration on page 1756, but the interface and addresses will be different. Ideally, the network interface you use is connected to a different Internet service provider for added redundancy.

When adding the second tunnel to the OSPF network, choose another unused subnet for the tunnel ends, 10.1.2.1 and 10.1.2.2 for example.

Adding the OSPF interface

OSPF uses the metric called cost when determining the best route, with lower costs being preferred. Up to now in this example, only the default cost of 10 has been used. Cost can be set only in the CLI.

The new IPsec tunnel will have its OSPF cost set higher than that of the default tunnel to ensure that it is only used if the first tunnel goes down. The new tunnel could be set to a cost of 200 compared to the default cost is 10. Such a large difference in cost will ensure this new tunnel will only be used as a last resort.

If the new tunnel is called tunnel_wan2, you would enter the following on both FortiGate units:

```
config router ospf
   config ospf-interface
      edit ospf_wan2
         set cost 200
         set interface tunnel_wan2
         set network-type point-to-point
      end
   end
```

Redundant OSPF routing over IPsec

This example sets up redundant secure communication between two remote networks using an Open Shortest Path First (OSPF) VPN connection. In this example, the HQ FortiGate unit will be called FortiGate 1 and the Branch FortiGate unit will be called FortiGate 2.

The steps include:

1. Creating redundant IPsec tunnels on FortiGate 1.
2. Configuring IP addresses and OSPF on FortiGate 1.
3. Configuring firewall addresses on FortiGate 1.
4. Configuring security policies on FortiGate 1.
5. Creating redundant IPsec tunnels for FortiGate 2.
6. Configuring IP addresses and OSPF on FortiGate 2.
7. Configuring firewall addresses on FortiGate 2.
8. Configuring security policies on FortiGate 2.

Creating redundant IPsec tunnels on FortiGate 1

1. Go to **VPN > IPsec > Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec > Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 2's wan2 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 1

1. Go to **System > Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.

3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.1
Remote IP	10.1.1.2

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.1
Remote IP	10.2.1.2

6. Go to **Router > Dynamic > OSPF** and enter the **Router ID** for FortiGate 1.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 1

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 1

1. Go to **Policy & Objects> Policy > IPv4**.
2. Create the four security policies required for both FortiGate 1's primary and secondary interfaces to connect to FortiGate 2's primary and secondary interfaces.

Creating redundant IPsec tunnels on FortiGate 2

1. Go to **VPN > IPsec > Tunnels**.
2. Select **Create New**, name the primary tunnel and select **Custom VPN Tunnel (No Template)**.
3. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan1 (the primary Internet-facing interface)
Pre-shared Key	Enter

4. Go to **VPN > IPsec > Tunnels**.
5. Select **Create New**, name the secondary tunnel and select **Custom VPN Tunnel (No Template)**.
6. Set the following:

Remote Gateway	Static IP Address
IP Address	FortiGate 1's wan1 IP
Local Interface	wan2 (the secondary Internet-facing interface)
Pre-shared Key	Enter

Configuring IP addresses and OSPF on FortiGate 2

1. Go to **System > Network > Interfaces**.
2. Select the arrow for **wan1** to expand the list.
3. Edit the primary tunnel interface and create IP addresses.

IP	10.1.1.2
Remote IP	10.1.1.1

4. Select the arrow for **wan2** to expand the list.
5. Edit the secondary tunnel interface and create IP addresses.

IP	10.2.1.2
Remote IP	10.2.1.1

6. Go to **Router > Dynamic > OSPF** and enter the **Router ID** for FortiGate 2.
7. Select **Create New** in the **Area** section.
8. Add the backbone area of **0.0.0.0**.
9. Select **Create New** in the **Networks** section.
10. Create the networks and select **Area 0.0.0.0** for each one.
11. Select **Create New** in the **Interfaces** section.
12. Create primary and secondary tunnel interfaces.
13. Set a **Cost** of **10** for the primary interface and **100** for the secondary interface.

Configuring firewall addresses on FortiGate 2

1. Go to **Policy & Objects > Objects > Addresses**.
2. Create/Edit the subnets behind FortiGate 1 and FortiGate 2.
3. Create/Edit the primary and secondary interfaces of FortiGate 2.

Configuring security policies on FortiGate 2

1. Go to **Policy & Objects> Policy > IPv4**.
2. Create the four security policies required for both FortiGate 2's primary and secondary interfaces to connect to FortiGate 1's primary and secondary interfaces.

Results

1. Go to **VPN > Monitor > IPsec Monitor** to verify the statuses of both the primary and secondary IPsec VPN tunnels on FortiGate 1 and FortiGate 2.
2. Go to **Router > Monitor > Routing**. Monitor to verify the routing table on FortiGate 1 and FortiGate 2. Type **OSPF** for the **Type** and select **Apply Filter** to verify the OSPF route.
3. Verify that traffic flows via the primary tunnel:
   - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracert to a PC2 set to IP address 10.21.1.00 behind FortiGate 2 and vise versa.
   - From PC1, you should see that the traffic goes through 10.1.1.2 which is the primary tunnel interface IP set on FortiGate 2.
   - From PC2, you should see the traffic goes through 10.1.1.1 which is the primary tunnel interface IP set on FortiGate 1.
4. The VPN network between the two OSPF networks uses the primary VPN connection. Disconnect the wan1 interface and confirm that the secondary tunnel will be used automatically to maintain a secure connection.
5. Verify the IPsec VPN tunnel statuses on FortiGate 1 and FortiGate 2. Both FortiGates should show that primary tunnel is DOWN and secondary tunnel is UP.
6. Go to **VPN > Monitor > IPsec Monitor** to verify the status.
7. Verify the routing table on FortiGate 1 and FortiGate 2.
   The secondary OSPF route (with cost = 100) appears on both FortiGate units.
8. Go to **Router > Monitor > Routing Monitor**. Type **OSPF** for the **Type** and select **Apply Filter** to verify OSPF route.
9. Verify that traffic flows via the secondary tunnel:
   - From a PC1 set to IP:10.20.1.100 behind FortiGate 1, run a tracert to a PC2 set to IP:10.21.1.100 behind FortiGate 2 and vice versa.
   - From PC1, you should see that the traffic goes through 10.2.1.2 which is the secondary tunnel interface IP set on FortiGate 2.
   - From PC2, you should see the traffic goes through 10.2.1.1 which is the secondary tunnel interface IP set on FortiGate 1.

OSPF over dynamic IPsec

This example shows how to create a dynamic IPsec VPN tunnel that allows OSPF.

Configuring IPsec on FortiGate 1

1. Go to **System > Status** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit "dial-up"
      set type dynamic
      set interface "wan1"
      set mode-cfg enable
      set proposal 3des-sha1
      set add-route disable
      set ipv4-start-ip 10.10.101.0
      set ipv4-end-ip 10.10.101.255
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit "dial-up-p2"
      set phase1name "dial-up"
      set proposal 3des-sha1 aes128-sha1
   next
end
```

Configuring OSPF on FortiGate 1

1. Go to **System > Status** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
   set router-id 172.20.120.22
      config area
         edit 0.0.0.0
         next
      end
      config network
         edit 1
            set prefix 10.10.101.0 255.255.255.0
         next
      end
      config redistribute "connected"
         set status enable
      end
      config redistribute "static"
         set status enable
      end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing OSPF traffic from **dial-up** to **port5**.
2. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing OSPF traffic from **port5** to **dial-up** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **System > Status** and enter the **CLI Console** widget
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit "dial-up-client"
      set interface "wan1"
      set mode-cfg enable
      set proposal 3des-sha1
      set add-route disable
      set remote-gw 172.20.120.22
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit "dial-up-client"
      set phase1name "dial-up-client"
      set proposal 3des-sha1 aes128-sha1
      set auto-negotiate enable
   next
end
```

Configuring OSPF on FortiGate 2

1. Go to **System > Status** and enter the **CLI Console** widget.
2. Create OSPF route.

```
config router ospf
   set router-id 172.20.120.15
      config area
         edit 0.0.0.0
         next
      end
      config network
         edit 1
            set prefix 10.10.101.0 255.255.255.0
         next
      end
      config redistribute "connected"
         set status enable
      end
      config redistribute "static"
         set status enable
      end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing OSPF traffic from **dial-up-client** to **port5**.
2. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing OSPF traffic from **port5** to **dial-up-client** interfaces.

Verifying the tunnel is up

Go to **VPN > Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Router > Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via OSPF.
2. From FortiGate 1, go to **System > Status**. Enter the CLI Console widget and type this command to verify OSPF neighbors:
   ```
   get router info ospf neighbor
   ```
3. From FortiGate 2, go to **Router > Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via OSPF.
4. From FortiGate 2, go to **System > Status**. Enter the CLI Console widget and type this command to verify OSPF neighbors:
   ```
   get router info ospf neighbor
   ```

BGP over dynamic IPsec

This example shows how to create a dynamic IPsec VPN tunnel that allows BGP.

Configuring IPsec on FortiGate 1

1. Go to **Policy & Objects > Objects > Addresses** and select create new **Address**.

Name	Remote_loop_int
Type	Subnet
Subnet/IP Range	10.10.10.10
Interface	any

2. Create an **Address Group**.

Group Name	VPN_DST
Show in Address List	enable
Members	Remote_loop_int all

3. Go to **System > Status** and enter the CLI Console widget.
4. Create phase 1:

```
config vpn ipsec phase1-interface
   edit Dialup
      set type dynamic
      set interface wan1
      set mode aggressive
      set peertype one
      set mode-cfg enable
      set proposal 3des-sha1 aes128-sha1
      set peerid dial
      set assign-ip disable
      set psksecret
   next
end
```

5. Create phase 2:

```
config vpn ipsec phase2-interface
   edit dial_p2
      set phase1name Dialup
      set proposal 3des-sha1 aes128-sha1
      set src-addr-type name
      set dst-addr-type name
      set src-name all
      set dst-name VPN_DST
   next
```

```
end
```

Configuring BGP on FortiGate 1

1. Go to **System > Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **20.20.20.20/255.255.255.255**.
3. Go to **System > Status** and enter the CLI Console widget.
4. Create a BGP route.

```
config router bgp
   set as 100
   set router-id 1.1.1.1
      config neighbor
         edit 10.10.10.10
            set ebgp-enforce-multihop enable
            set remote-as 200
            set update-source loop
         next
      end
      config redistribute connected
         set status enable
      end
end
```

Adding policies on FortiGate 1

1. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Configuring IPsec on FortiGate 2

1. Go to **System > Status** and enter the CLI Console widget.
2. Create phase 1:

```
config vpn ipsec phase1-interface
   edit Dialup
      set interface wan1
      set mode aggressive
      set mode-cfg enable
      set proposal 3des-sha1 aes128-sha1
      set localid dial
      set remote-gw 172.20.120.22
      set assign-ip disable
      set psksecret
   next
end
```

3. Create phase 2:

```
config vpn ipsec phase2-interface
   edit dial_p2
      set phase1name Dialup
      set proposal 3des-sha1 aes128-sha1
      set keepalive enable
```

```
    next
end
```

Configuring BGP on FortiGate 2

1. Go to **System > Network > Interfaces** and create a Loopback interface.
2. Set **IP/Network Mask** to **10.10.10.10/255.255.255.255**.
3. Go to **System > Status** and enter the **CLI Console** widget.
4. Create a BGP route.

```
config router bgp
   set as 200
   set router-id 1.1.1.2
      config neighbor
         edit 20.20.20.20
            set ebgp-enforce-multihop enable
            set remote-as 100
            set update-source loop
         next
      end
      config redistribute connected
         set status enable
      end
end
```

Adding policies on FortiGate 2

1. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing BGP traffic from **Dialup** to **loop** interfaces.
2. Go to **Policy & Objects > Policy > IPv4** and create a policy allowing BGP traffic from **loop** to **Dialup** interfaces.

Adding a static route on FortiGate 2

Go to **Router > Static > Static Routes** and add a route to the remote Loopback interface via Dialup interface.

Destination IP/Mask	20.20.20.20/255.255.255.255
Device	Dialup
Administrative Distance	10

Verifying the tunnel is up

Go to **VPN > Monitor > IPsec Monitor** to verify that the tunnel is **Up**.

Results

1. From FortiGate 1, go to **Router > Monitor > Routing Monitor** and verify that routes from FortiGate 2 were successfully advertised to FortiGate 1 via BGP.

2. From FortiGate 1, go to **System > Status**.
3. Enter the **CLI Console** widget and type this command to verify BGP neighbors:
```
get router info bgp summary
```
4. From FortiGate 2, go to **Router > Monitor > Routing Monitor** and verify that routes from FortiGate 1 were successfully advertised to FortiGate 2 via BGP.
5. From FortiGate 2, go to **System > Status**.
6. Enter the **CLI Console** widget and type this command to verify BGP neighbors:
```
get router info bgp summary
```

Logging and monitoring

This section provides some general logging and monitoring procedures for VPNs.

The following topics are included in this section:

Monitoring VPN connections
Logging VPN events

Monitoring VPN connections

You can use the monitor to view activity on IPsec VPN tunnels and to start or stop those tunnels. The display provides a list of addresses, proxy IDs, and timeout information for all active tunnels.

Monitoring connections to remote peers

The list of tunnels provides information about VPN connections to remote peers that have static IP addresses or domain names. You can use this list to view status and IP addressing information for each tunnel configuration. You can also start and stop individual tunnels from the list.

To view the list of static-IP and dynamic-DNS tunnels go to **VPN > Monitor > IPsec Monitor**.

Monitoring dialup IPsec connections

The list of dialup tunnels provides information about the status of tunnels that have been established for dialup clients. The list displays the IP addresses of dialup clients and the names of all active tunnels. The number of tunnels shown in the list can change as dialup clients connect and disconnect.

To view the list of dialup tunnels go to **VPN > Monitor > IPsec Monitor**.

If you take down an active tunnel while a dialup client such as FortiClient is still connected, FortiClient will continue to show the tunnel connected and idle. The dialup client must disconnect before another tunnel can be initiated.

The list of dialup tunnels displays the following statistics:

- The Name column displays the name of the tunnel.
- The meaning of the value in the Remote gateway column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel, the Remote gateway column displays either the public IP address and UDP port of the remote host device (on which the FortiClient Endpoint Security application is installed), or if a NAT device exists in front of the remote host, the Remote gateway column displays the public IP address and UDP port of the remote host.
  - When a FortiGate dialup client establishes a tunnel, the Remote gateway column displays the public IP address and UDP port of the FortiGate dialup client.
- The Username column displays the peer ID, certificate name, or XAuth user name of the dialup client (if a peer ID, certificate name, or XAuth user name was assigned to the dialup client for authentication purposes).
- The Timeout column displays the time before the next key exchange. The time is calculated by subtracting the time elapsed since the last key exchange from the keylife.

- The Proxy ID Source column displays the IP addresses of the hosts, servers, or private networks behind the FortiGate unit. A network range may be displayed if the source address in the security encryption policy was expressed as a range of IP addresses.
- The meaning of the value in the Proxy ID Destination column changes, depending on the configuration of the network at the far end:
  - When a FortiClient dialup client establishes a tunnel:
  - If VIP addresses are not used and the remote host connects to the Internet directly, the Proxy ID Destination field displays the public IP address of the Network Interface Card (NIC) in the remote host.
  - If VIP addresses are not used and the remote host is behind a NAT device, the Proxy ID Destination field displays the private IP address of the NIC in the remote host.
  - If VIP addresses were configured (manually or through FortiGate DHCP relay), the Proxy ID Destination field displays either the VIP address belonging to a FortiClient dialup client, or a subnet address from which VIP addresses were assigned.
- When a FortiGate dialup client establishes a tunnel, the Proxy ID Destination field displays the IP address of the remote private network.

Logging VPN events

You can configure the FortiGate unit to log VPN events. For IPsec VPNs, Phase 1 and Phase 2 authentication and encryption events are logged. For information about how to interpret log messages, see the FortiGate Log Message Reference.

To log VPN events

1. Go to **Log & Report > Log Config > Log Settings**.
2. Verify that the **VPN activity event** option is selected.
3. Select **Apply**.

To view event logs

1. Go to **Log & Report > Event Log > VPN**.
2. Select the **Log location**.

Sending tunnel statistics to FortiAnalyzer

By default, logged events include tunnel-up and tunnel-down status events. Other events, by default, will appear in the FortiAnalyzer report as "No Data Available". More accurate results require logs with `action=tunnel-stats`, which is used in generating reports on the FortiAnalyzer (rather than the tunnel-up and tunnel-down event logs). The FortiGate does not, by default, send `tunnel-stats` information.

To allow VPN `tunnel-stats` to be sent to FortiAnalyzer, configure the FortiGate unit as follows using the CLI:

```
config system settings
   set vpn-stats-log ipsec ssl
   set vpn-stats-period 300
end
```

Troubleshooting

This section contains tips to help you with some common challenges of IPsec VPNs.

A VPN connection has multiple stages that can be confirmed to ensure the connection is working properly. It is easiest to see if the final stage is successful first since if it is successful the other stages will be working properly. Otherwise, you will need to work back through the stages to see where the problem is located.

When a VPN connection is properly established, traffic will flow from one end to the other as if both ends were physically in the same place. If you can determine the connection is working properly then any problems are likely problems with your applications.

On some FortiGate units, such as the FortiGate 94D, you cannot ping over the IPsec tunnel without first setting a source-IP. In this scenario, you must assign an IP address to the virtual IPSEC VPN interface. Anything sourced from the FortiGate going over the VPN will use this IP address.

If the egress/outgoing interface (determined by kernel route) has an IP address, then use the IP address of the egress/outgoing interface. Otherwise, use the IP address of the first interface from the interface list (that has an IP address).

The first diagnostic command worth running, in any IPsec VPN troubleshooting situation, is the following:

```
diagnose vpn tunnel list
```

This command is very useful for gathering statistical data such as the number of packets encrypted versus decrypted, the number of bytes sent versus received, the SPI identifier, etc. This kind of information in the resulting output can make all the difference in determining the issue with the VPN.

Another appropriate diagnostic command worth trying is:

```
diagnose debug flow
```

This command will inform you of any lack of firewall policy, lack of forwarding route, and of policy ordering issues.

The following is a list of such potential issues. Bear in mind that the troubleshooting suggestions below are not exhaustive, and may not reflect your network topology.

The options to configure policy-based IPsec VPN are unavailable.

Go to **System > Config > Features**. Select **Show More** and turn on **Policy-based IPsec VPN**.

The VPN connection attempt fails.

If your VPN fails to connect, check the following:

- Ensure that the **pre-shared keys** match exactly (see The pre-shared key does not match (PSK mismatch error). below).
- Ensure that both ends use the same P1 and P2 proposal settings (seeThe SA proposals do not match (SA proposal mismatch). below).
- Ensure that you have allowed inbound and outbound traffic for all necessary network services, especially if services such as DNS or DHCP are having problems.
- Check that a static route has been configured properly to allow routing of VPN traffic.

- Ensure that your FortiGate unit is in NAT/Route mode, rather than Transparent.
- Check your NAT settings, enabling NAT traversal in the Phase 1 configuration while disabling NAT in the security policy. You might need to pin the PAT/NAT session table, or use some of kind of NAT-T keepalive to avoid the expiration of your PAT/NAT translation.
- Ensure that both ends of the VPN tunnel are using Main mode, unless multiple dial-up tunnels are being used.
- If you have multiple dial-up IPsec VPNs, ensure that the Peer ID is configured properly on the
- FortiGate and that clients have specified the correct Local ID.
- If you are using FortiClient, ensure that your version is compatible with the FortiGate firmware by reading the FortiOS Release Notes.
- If you are using Perfect Forward Secrecy (PFS), ensure that it is used on both peers. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- Ensure that the **Quick Mode selectors** are correctly configured. If part of the setup currently uses firewall addresses or address groups, try changing it to either specify the IP addresses or use an expanded address range. This is especially useful if the remote endpoint is not a FortiGate device.
- If XAUTH is enabled, ensure that the settings are the same for both ends, and that the FortiGate unit is set to **Enable as Server**.
- Check IPsec VPN Maximum Transmission Unit (MTU) size. A 1500 byte MTU is going to exceed the overhead of the ESP-header, including the additional ip_header,etc. You can use the `diagnose vpn tunnel list` command to troubleshoot this.
- If your FortiGate unit is behind a NAT device, such as a router, configure port forwarding for UDP ports 500 and 4500.
- Remove any Phase 1 or Phase 2 configurations that are not in use. If a duplicate instance of the VPN tunnel appears on the IPsec Monitor, reboot your FortiGate unit to try and clear the entry.

If you are still unable to connect to the VPN tunnel, run the following diagnostic command in the CLI:

```
diagnose debug application ike -1
diagnose debug enable
```

The resulting output may indicate where the problem is occurring. When you are finished, disable the diagnostics by using the following command:

```
diagnose debug reset
diagnose debug disable
```

The VPN tunnel goes down frequently.

If your VPN tunnel goes down often, check the Phase 2 settings and either increase the **Keylife** value or enable **Autokey Keep Alive**.

The pre-shared key does not match (PSK mismatch error).

It is possible to identify a PSK mismatch using the following combination of CLI commands:

```
diag debug app ike filter name "phase1-name"
diag debug app ike -1
diag debug enable
```

This will provide you with clues as to any PSK or other proposal issues. If it is a PSK mismatch, you should see something similar to the following output:

```
ike 0:TRX:322: PSK auth failed: probable pre-shared key mismatch
ike Negotiate SA Error:
```

The SA proposals do not match (SA proposal mismatch).

The most common problem with IPsec VPN tunnels is a mismatch between the proposals offered between each party. Without a match and proposal agreement, Phase 1 can never establish. Use the following command to show the proposals presented by both parties.

```
diag debug app ike -1
diag debug enable
```

The resulting output should include something similar to the following, where blue represents the remote VPN device, and green represents the local FortiGate.

```
responder received SA_INIT msg
incoming proposal:
proposal id = 1:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=AES_CBC (key_len = 256)
         type=INTEGR, val=AUTH_HMAC_SHA_96
         type=PRF, val=PRF_HMAC_SHA
         type=DH_GROUP, val=1536.
proposal id = 2:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=3DES_CBC
         type=INTEGR, val=AUTH_HMAC_SHA_2_256_128
         type=PRF, val=PRF_HMAC_SHA2_256
         type=DH_GROUP, val=1536.
proposal id = 1:
   protocol = IKEv2:
      encapsulation = IKEv2/none
         type=ENCR, val=AES_CBC (key_len = 128)
         type=INTEGR, val=AUTH_HMAC_SHA_96
         type=PRF, val=PRF_HMAC_SHA
         type=DH_GROUP, val=1536.
```

Pre-existing IPsec VPN tunnels need to be cleared.

Should you need to clear an IKE gateway, use the following commands:

```
diagnose vpn ike restart
diagnose vpn ike gateway clear
```

LAN interface connection

To confirm whether a VPN connection over LAN interfaces has been configured correctly, issue a ping or traceroute command on the network behind the FortiGate unit to test the connection to a computer on the remote network. If the connection is properly configured, a VPN tunnel will be established automatically when the first data packet destined for the remote network is intercepted by the FortiGate unit.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel. You can confirm this by going to **VPN > Monitor > IPsec**

Monitor where you will be able to see your connection. A green arrow means the tunnel is up and currently processing traffic. A red arrow means the tunnel is not processing traffic, and this VPN connection has a problem.

If the connection has problems, see Troubleshooting VPN connections on page 1774.

Dialup connection

A dialup VPN connection has additional steps. To confirm that a VPN between a local network and a dialup client has been configured correctly, at the dialup client, issue a ping command to test the connection to the local network. The VPN tunnel initializes when the dialup client attempts to connect.

If the ping or traceroute fail, it indicates a connection problem between the two ends of the tunnel. This may or may not indicate problems with the VPN tunnel, or dialup client. As with the LAN connection, confirm the VPN tunnel is established by checking **VPN > Monitor > IPsec Monitor**.

Troubleshooting VPN connections

If you have determined that your VPN connection is not working properly through Troubleshooting on page 1771, the next step is to verify that you have a phase2 connection.

If traffic is not passing through the FortiGate unit as you expect, ensure the traffic does not contain IPcomp packets (IP protocol 108, RFC 3173). FortiGate units do not allow IPcomp packets, they compress packet payload, preventing it from being scanned.

Testing Phase 1 and 2 connections is a bit more difficult than testing the working VPN. This is because they require diagnose CLI commands. These commands are typically used by Fortinet customer support to discover more information about your FortiGate unit and its current configuration.

Before you begin troubleshooting, you must:

- Configure FortiGate units on both ends for interface VPN
- Record the information in your VPN Phase 1 and Phase 2 configurations - for our example here the remote IP address is 10.11.101.10 and the names of the phases are Phase 1 and Phase 2
- Install a telnet or SSH client such as putty that allows logging of output
- Ensure that the admin interface supports your chosen connection protocol so you can connect to your FortiGate unit admin interface.

For this example, default values were used unless stated otherwise.

To get diagnose information for the VPN connection - CLI

1. Log into the CLI as admin with the output being logged to a file.
2. Stop any diagnose debug sessions that are currently running with the CLI command
   ```
   diagnose debug disable
   ```
3. Clear any existing log-filters by running
   ```
   diagnose vpn ike log-filter clear
   ```
4. Set the log-filter to the IP address of the remote computer (10.11.101.10). This filters out all VPN connections except ones to the IP address we are concerned with. The command is
   ```
   diagnose vpn ike log-filter dst-addr4 10.11.101.10.
   ```
5. Set up the commands to output the VPN handshaking. The commands are:
   ```
   diagnose debug app ike 255
   ```

```
diagnose debug enable
```

6. Have the remote FortiGate initiate the VPN connection in the web-based manager by going to **VPN > Monitor** and selecting **Bring up**.

   This makes the remote FortiGate the initiator and the local FortiGate becomes the responder. Establishing the connection in this manner means the local FortiGate will have its configuration information as well as the information the remote computer sends. Having both sets of information locally makes it easier to troubleshoot your VPN connection.
7. Watch the screen for output, and after roughly 15 seconds enter the following CLI command to stop the output.
   ```
   diagnose debug disable
   ```
8. If needed, save the log file of this output to a file on your local computer. Saving the output to a file can make it easier to search for a particular phrase, and is useful for comparisons.

To troubleshoot a phase1 VPN connection

Using the output from To get diagnose information for the VPN connection - CLI on page 1774, search for the word `proposal` in the output. It may occur once indicating a successful connection, or it will occur two or more times for an unsuccessful connection — there will be one proposal listed for each end of the tunnel and each possible combination in their settings. For example if 10.11.101.10 selected both Diffie-Hellman Groups 1 and 5, that would be at least 2 proposals set.

A successful negotiation proposal will look similar to

```
IPsec SA connect 26 10.12.101.10->10.11.101.10:500
config found
created connection: 0x2f55860 26 10.12.101.10->10.11.101.10:500
IPsec SA connect 26 10.12.101.10->10.11.101.10:500 negotiating
no suitable ISAKMP SA, queuing quick-mode request and initiating ISAKMP SA negotiation
initiator: main mode is sending 1st message...
cookie 3db6afe559e3df0f/0000000000000000
out [encryption]
sent IKE msg (ident-i1send): 10.12.101.10:500->10.11.101.10:500, len=264,
    id=3db6afe559e3df0f/0000000000000000
diaike 0: comes 10.12.101.1:500->10.11.101.1:500,ifindex=26....
```

Note the phrase "`initiator: main mode is sending 1st message...`" which shows you the handshake between the ends of the tunnel is in progress. Initiator shows the remote unit is sending the first message.

VPN troubleshooting tips

More in-depth VPN troubleshooting can be found in the Troubleshooting guide.

Attempting hardware offloading beyond SHA1

If you are trying to off-load VPN processing to a network processing unit (NPU), remember that only SHA1 authentication is supported. For high levels of authentication such as SHA256, SHA384, and SHA512 hardware offloading is not an option — all VPN processing must be done in software.

Check Phase 1 proposal settings

Ensure that both sides have at least one Phase 1 proposal in common. Otherwise they will not connect. If there are many proposals in the list, this will slow down the negotiating of Phase 1. If its too slow, the connection may timeout before completing. If this happens, try removing some of the unused proposals.

NPU offloading is supported when the local gateway is a loopback interface.

Check your routing

If routing is not properly configured with an entry for the remote end of the VPN tunnel, traffic will not flow properly. You may need static routes on both ends of the tunnel. If routing is the problem, the proposal will likely setup properly but no traffic will flow.

Try enabling XAuth

If one end of an attempted VPN tunnel is using XAuth and the other end is not, the connection attempt will fail. The log messages for the attempted connection will not mention XAuth is the reason, but when connections are failing it is a good idea to ensure both ends have the same XAuth settings. If you do not know the other end's settings enable or disable XAuth on your end to see if that is the problem.

General troubleshooting tips

Most connection failures are due to a configuration mismatch between the FortiGate unit and the remote peer. In general, begin troubleshooting an IPsec VPN connection failure as follows:

1. Ping the remote network or client to verify whether the connection is up. See General troubleshooting tips on page 1776.
2. Traceroute the remote network or client. If DNS is working, you can use domain names. Otherwise use IP addresses.
3. Check the routing behind the dialup client. Routing problems may be affecting DHCP. If this appears to be the case, configure a DHCP relay service to enable DHCP requests to be relayed to a DHCP server on or behind the FortiGate server.
4. Verify the configuration of the FortiGate unit and the remote peer. Check the following IPsec parameters:
   - The mode setting for ID protection (main or aggressive) on both VPN peers must be identical.
   - The authentication method (preshared keys or certificates) used by the client must be supported on the FortiGate unit and configured properly.
   - If preshared keys are being used for authentication purposes, both VPN peers must have identical preshared keys.
   - The remote client must have at least one set of Phase 1 encryption, authentication, and Diffie-Hellman settings that match corresponding settings on the FortiGate unit.
   - Both VPN peers must have the same NAT traversal setting (enabled or disabled).
   - The remote client must have at least one set of Phase 2 encryption and authentication algorithm settings that match the corresponding settings on the FortiGate unit.
   - If you are using manual keys to establish a tunnel, the **Remote SPI** setting on the FortiGate unit must be identical to the **Local SPI** setting on the remote peer, and vise versa.
5. To correct the problem, see the following table.

VPN trouble-shooting tips

Configuration problem	Correction
Mode settings do not match.	Select complementary mode settings. See Phase 1 parameters on page 1581.
Peer ID or certificate name of the remote peer or dialup client is not recognized by FortiGate VPN server.	Check Phase 1 configuration. Depending on the Remote Gateway and Authentication Method settings, you have a choice of options to authenticate FortiGate dialup clients or VPN peers by ID or certificate name (see Phase 1 parameters on page 1581). If you are configuring authentication parameters for FortiClient dialup clients, refer to the Authenticating FortiClient Dialup Clients Technical Note.
Preshared keys do not match.	Reenter the preshared key. See Phase 1 parameters on page 1581.
Phase 1 or Phase 2 key exchange proposals are mismatched.	Make sure that both VPN peers have at least one set of proposals in common for each phase. See Phase 1 parameters on page 1581 and Phase 2 parameters on page 1598.
NAT traversal settings are mismatched.	Select or clear both options as required. See Phase 1 parameters on page 1581 and Phase 1 parameters on page 1581.

A word about NAT devices

When a device with NAT capabilities is located between two VPN peers or a VPN peer and a dialup client, that device must be NAT traversal (NAT-T) compatible for encrypted traffic to pass through the NAT device. For more information, see Phase 1 parameters on page 1581.

Chapter 15 - IPv6

The origins of Internet Protocol Version 6 (IPv6) date back to December 1998 with the publication of RFC 2460, which describes IPv6 as the successor to IPv4, the standard communications protocol still in use by the majority of users today. This transition away from IPv4 was a direct response to the foreseeable exhaustion of 32-bit IPv4 addresses, which are virtually all but assigned—all 4.3 billion.

IPv4 uses 32-bit addresses, which means that there is a theoretical address limit of 2 to the power of 32. The IPv6 address scheme is based on a 128-bit address, resulting in a theoretical address limit of 2 to the power of 128.

Possible addresses:

IPv4 = Roughly 4.3 billion

IPv6 = Over 340 undecillion (340 followed by 36 digits)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,
000,000,000 devices with an IP address. That's 42 quintillion devices, so it's unlikely that we will ever need to worry about the availability of IPv6 addresses.

Aside from the difference of possible addresses, there is also the different formatting of the addresses. A computer would view an IPv4 address as a 32-bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period:

```
10101100.00010000.11111110.00000001
```

To make the number more user-friendly, we translate the address into decimal, again 4 octets separated by a period:

```
172.16.254.1
```

A computer would view an IPv6 address as a 128-bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon:

```
0010000000000001:0000110110111:0000000000000000:0000000000010:0000000000000000:0000000000000000:0000000000000000:0000000000100000
```

To make this number a little more user-friendly, we translate it into hexadecimal, again 8 octets separated by a colon, for example:

```
2001:0db8:0000:0002:0000:0000:0000:0020
```

We can further simplify the above address. Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, the above address can be reduced to:

```
2001:0db8:0000:0002:0:0:0:20
```

or

```
2001:db8:0:2::20
```

IPv6 packet structure

Each IPv6 packet consists of a mandatory fixed header and optional extension headers, and carries a payload, which is typically either a datagram and/or Transport Layer information. The payload could also contain data for the Internet Layer or Link Layer. Unlike IPv4, IPv6 packets aren't fragmented by routers, requiring hosts to implement Maximum Transmission Unit (MTU) Path Discovery for MTUs larger than the smallest MTU (which is 1280 octets).

Jumbograms and jumbo payloads

In IPv6, packets which exceed the MTU of the underlying network are labelled jumbograms, which consist of a jumbo payload. A jumbogram typically exceeds the IP MTU size limit of 65,535 octets, and provides the jumbo payload option, which can allow up to nearly 4GiB of payload data, as defined in RFC 2675. When the MTU is determined to be too large, the receiving host sends a 'Packet too Big' ICMPv6 type 2 message to the sender.

Fragmentation and reassembly

As noted, packets that are too large for the MTU require hosts to perform MTU Path Discovery to determine the maximum size of packets to send. Packets that are too large require a 'Fragment' extension header, to divide the payload into segments that are 8 octets in length (except for the last fragment, which is smaller). Packets are reassembled according to the extension header and the fragment offset.

Benefits of IPv6

Some of the benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local, and global address space

IPv6 Features

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. Go to **System > Config > Features**, enable IPv6, and click **Apply**.

The following IPv6 features are available from the FortiOS web manager:

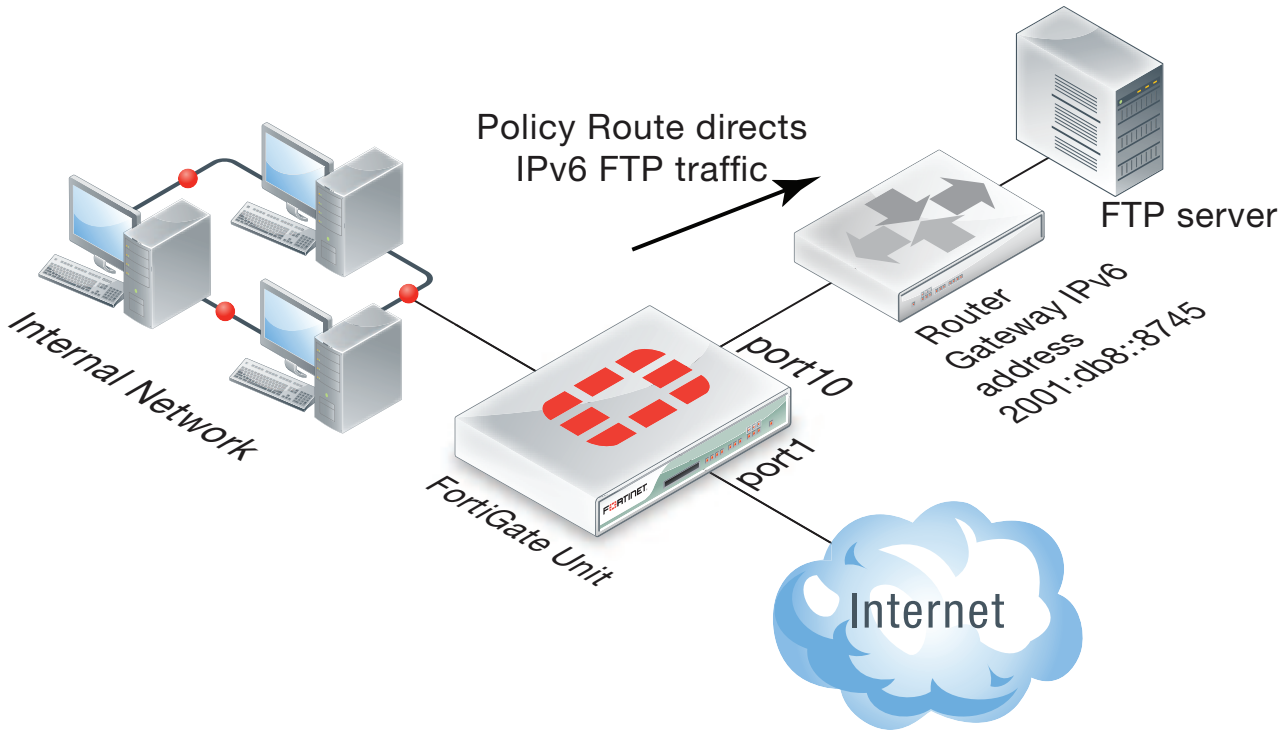
IPv6 policies
IPv6 Network Address Translation
ICMPv6
IPv6 in dynamic routing
Dual stack routing
IPv6 tunnelling
SIP over IPv6
New Fortinet FortiGate IPv6 MIB fields
IPv6 Per-IP traffic shaper
DHCPv6
IPv6 forwarding
Obtaining IPv6 addresses from an IPv6 DHCP server

IPv6 policies

IPv6 security policies are created both for an IPv6 network and a transitional network. A transitional network is a network that is transitioning over to IPv6 but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature under **System > Config > Features**.

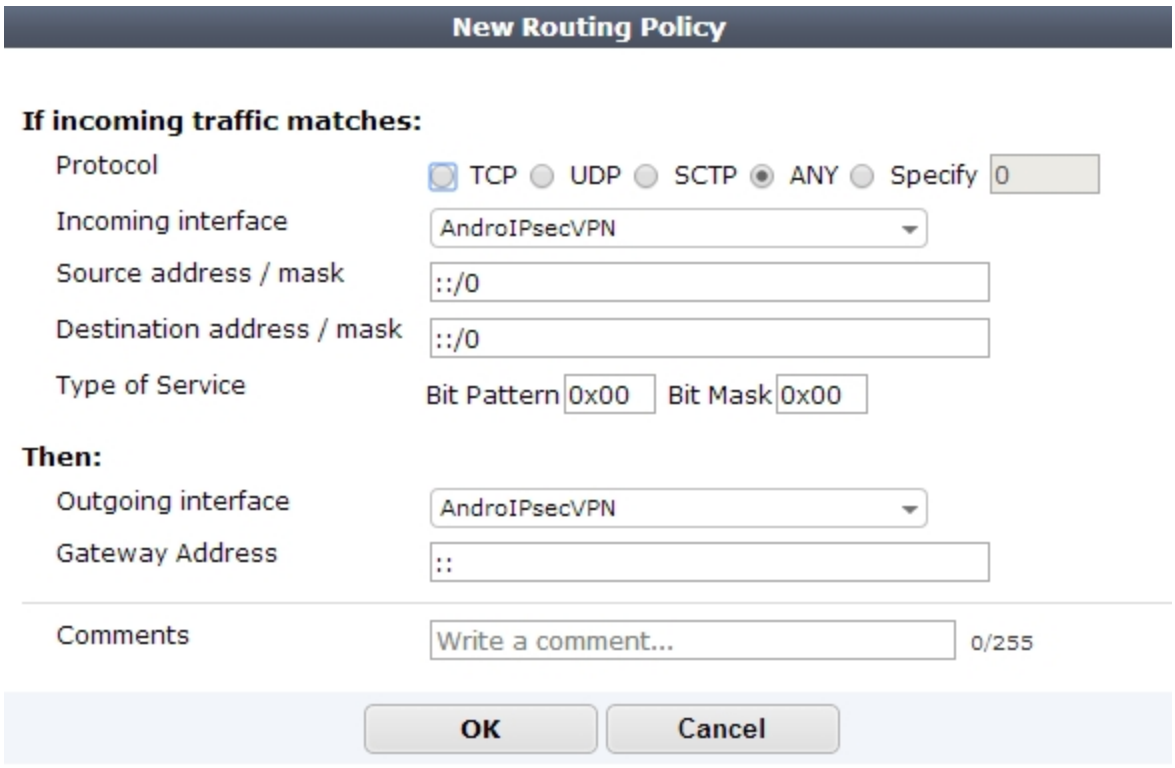
IPv6 policy route



IPv6 policy routing

IPv6 policy routing functions in the same was as IPv4 policy routing. To add an IPv6 policy route, go to **Router > Static > Policy Routes** and select **Create New > IPv6 Policy Route**.

Adding an IPv6 Policy route



You can also use the following command to add IPv6 policy routes:

```
config router policy6
   edit 0
      set input-device <interface>
      set src <ipv6_ip>
      set dst <ipv6_ip>
      set protocol <0-255>
      set gateway <ipv6_ip>
      set output-device <interface>
      set tos <bit_pattern>
      set tos-mask <bit_mask>
   end
```

IPv6 security policies

IPv6 security policies support all the features supported by IPv4 security policies:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP, and ICAP).
- All traffic shaping options, including: shared traffic shaping, reverse shared traffic shaping, and per-IP traffic shaping.
- All user and device authentication options.

IPv6 Policy Monitor

Once policies have been configured and enabled it is useful to be able to monitor them. To get an overview about what sort of traffic the policies are processing, go to **Policy & Objects > Monitor > IPv6 Policy Monitor**.

IPv6 explicit web proxy

You can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the Explicit Proxy from the dashboard.
- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Go to **System > Dashboard > Status** and turn on **Explicit Proxy** under the **Features > Security Features** widget. Click **Apply**.
2. Enter the following CLI command to enable the IPv6 explicit web proxy:

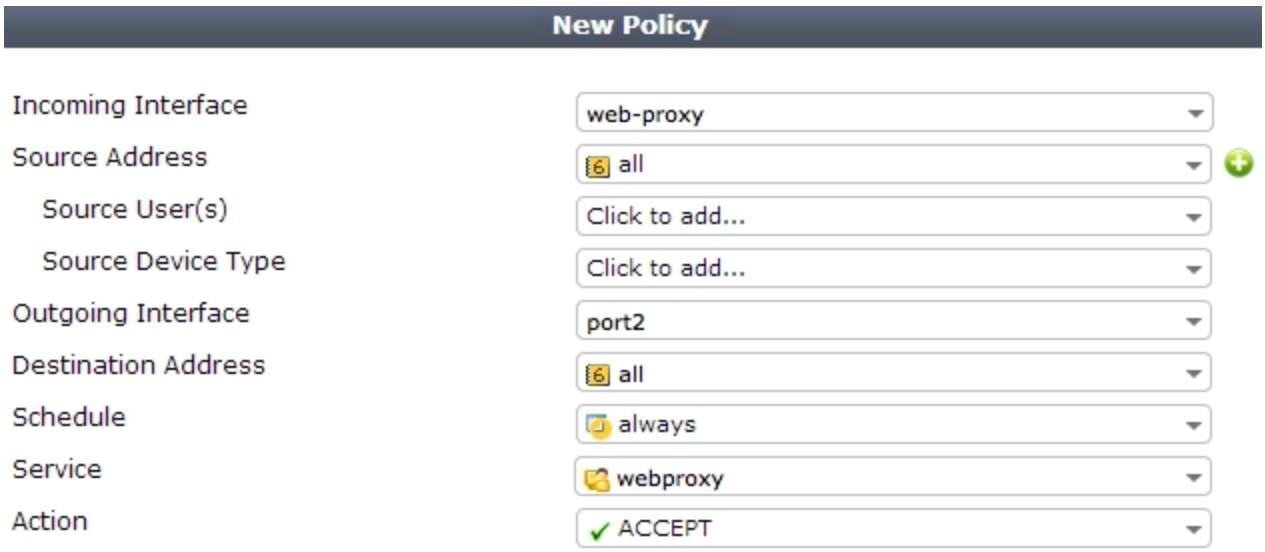
```
config web-proxy explicit
   set status enable
   set ipv6-status enable
end
```

3. Go to **System > Network > Interfaces** and edit the **internal** interface, select **Enable Explicit Web Proxy** and select **OK**.
4. Go to **Policy & Objects > Policy > IPv6** and select **Create New** to add an IPv6 explicit web proxy security policy with the following settings shown.

   This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy, you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Example IPv6 Explicit Web Proxy security policy



Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require users to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy, use the following command:

```
config web-proxy explicit
   set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
   set outgoing-ip6 2001:db8:0:2::50
end
```

VIP64

VIP64 policies can be used to configure static NAT virtual IPv6 address for IPv4 addresses. VIP64 can be configured from the CLI using the following commands:

```
config firewall vip64
   edit <zname_str>
```

```
    set arp-reply {enable | disable}
    set color <color_int>
    set comment <comment_str>
    set extip <address_ipv6>[-address_ipv6]
    set extport <port_int>
    set id <id_num_str>
    set mappedip [<start_ipv4>-<end_ipv4>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <addr_str>
end
```

VIP64 CLI Variables and Defaults

Variable	Description	Default
`<zname_str>`	Enter the name of this virtual IP address.	No default.
`arp-reply {enable | disable}`	Select to respond to ARP requests for this virtual IP address.	enable
`color <color_int>`	Enter the number of the color to use for the group icon in the web-based manager.	0
`comment <comment_str>`	Enter comments relevant to the configured virtual IP.	No default.
`extip <address_ipv6>[-address_ipv6]`	Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. To configure a dynamic virtual IP that accepts connections destined for any IP address, set `extip` to ::.	::
`extport <port_int>`	Enter the external port number that you want to map to a port number on the destination network. This option only appears if `portforward` is enabled. If `portforward` is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set `extport` to the first port number in the range. Then set `mappedport` to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the `extport` port number range.	0

Variable	Description	Default
`id <id_num_str>`	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
`mappedip [<start_ipv4>-<end_ipv4>]`	Enter the IP address or IP address range on the destination network to which the external IP address is mapped. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as a single IP address to create a one-to-many mapping.	0.0.0.0
`mappedport <port_int>`	Enter the port number on the destination network to which the external port number is mapped. You can also enter a port number range to forward packets to multiple ports on the destination network. For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.	0
`portforward {enable | disable}`	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring `extport` and `mappedport`.	disable
`src-filter <addr_str>`	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x:x:x:x:x:x:x:x/n). Separate addresses with spaces.	null

VIP46 policies can be used to configure static NAT virtual IPv4 address for IPv6 addresses. VIP46 can be configured from the CLI using the following commands (see the table below for variable details):

```
config firewall vip46
   edit <name_str>
      set arp-reply {enable | disable}
      set color <color_int>
```

```
    set comment <comment_str>
    set extip <address_ipv4>[-address_ipv4]
    set extport <port_int>
    set id <id_num_str>
    set mappedip [<start_ipv6>-<end_ipv6>]
    set mappedport <port_int>
    set portforward {enable | disable}
    set src-filter <add_str>
end
```

VIP46 CLI Variables and Defaults

Variable	Description	Default
`<name_str>`	Enter the name of this virtual IP address.	No default.
`arp-reply {enable | disable}`	Select to respond to ARP requests for this virtual IP address.	enable
`color <color_int>`	Enter the number of the color to use for the group icon in the web-based manager.	0
`comment <comment_str>`	Enter comments relevant to the configured virtual IP.	No default.
`extip <address_ipv4>[-address_ipv4]`	Enter the IP address or address range on the external interface that you want to map to an address or address range on the destination network. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. To configure a dynamic virtual IP that accepts connections destined for any IP address, set `extip` to 0.0.0.0.	0.0.0.0
`extport <port_int>`	Enter the external port number that you want to map to a port number on the destination network. This option only appears if `portforward` is enabled. If `portforward` is enabled and you want to configure a static NAT virtual IP that maps a range of external port numbers to a range of destination port numbers, set `extport` to the first port number in the range. Then set `mappedport` to the start and end of the destination port range. The FortiGate unit automatically calculates the end of the `extport` port number range.	0

Variable	Description	Default
`id <id_num_str>`	Enter a unique identification number for the configured virtual IP. Not checked for uniqueness. Range 0 - 65535.	No default.
`mappedip [<start_ipv6>-<end_ipv6>]`	Enter the IP address or IP address range on the destination network to which the external IP address is mapped. If mappedip is an IP address range, the FortiGate unit uses `extip` as the first IP address in the external IP address range, and calculates the last IP address required to create an equal number of external and mapped IP addresses for one-to-one mapping. If `mappedip` is an IP address range, the FortiGate unit uses `extip` as a single IP address to create a one-to-many mapping.	::
`mappedport <port_int>`	Enter the port number on the destination network to which the external port number is mapped. You can also enter a port number range to forward packets to multiple ports on the destination network. For a static NAT virtual IP, if you add a map to port range the FortiGate unit calculates the external port number range.	0
`portforward {enable | disable}`	Select to enable port forwarding. You must also specify the port forwarding mappings by configuring `extport` and `mappedport`.	disable
`src-filter <addr_str>`	Enter a source address filter. Each address must be in the form of an IPv4 subnet (x.x.x.x/n). Separate addresses with spaces.	null

IPv6 Network Address Translation

NAT66, NAT64, and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities withIPv6-IPv4 tunnelling or dual stack configurations. The commands are available only in the CLI.

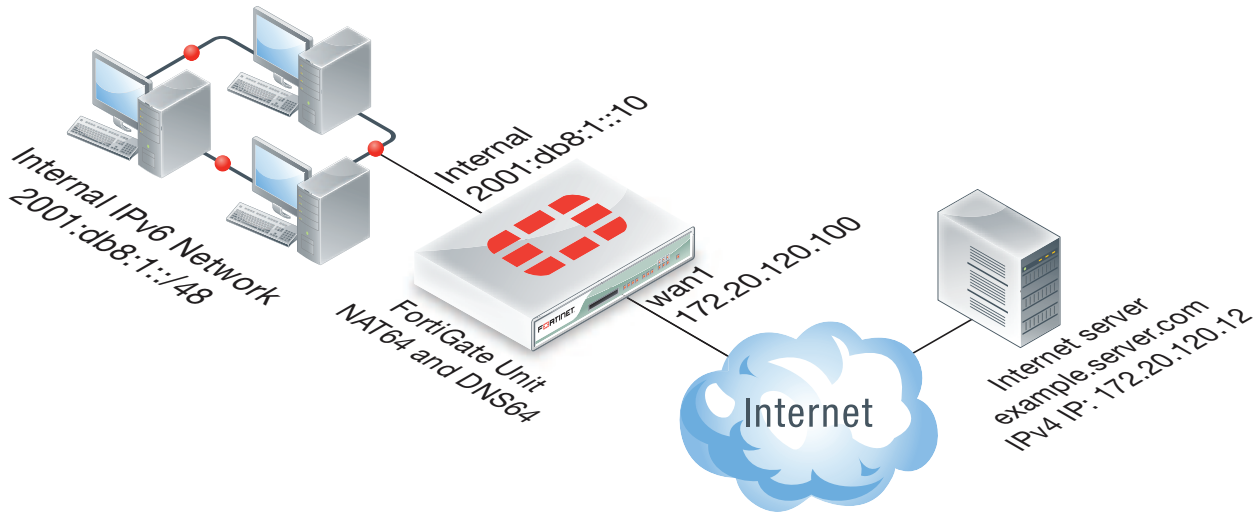
Fortinet supports all features described in RFC 6146. However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in RFC 6147.

NAT64 and DNS64 (DNS proxy)

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. 'DNS proxy' and 'DNS64' are interchangeable terms.

Example NAT64 configuration



With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform the IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

To enable NAT64 and DNS64, use the following CLI commands:

Enable NAT64

```
config system nat64
   set status enable
end
```

Enable the DNS proxy on the IPv6 interface

```
config system dns-server
   edit internal
   end
```

In your DHCP6 configuration, configure the IPv6 interface IP address as the DNS6 server IP address. The FortiGate will proxy DNS requests to the system DNS server.

```
config system dhcp6 server
   edit 1
      set interface internal
      config ip-range
         edit 1
            set start-ip 2001:db8:1::11
            set end-ip 2001:db8:1::20
         end
      set dns-server1 2001:db8:1::10
   end
```

NAT64 policies

You can configure security policies for NAT64 using the web-based manager. For these options to appear, the feature must be enabled using **Feature Select**. You can then configure the policies under **Policy & Objects > Policy > NAT64**.

NAT64 policies and can also be configured from the CLI using the following command:

```
config firewall policy64
```

In the following section, you will configure a NAT64 policy that allows connections from an internal IPv6 network to an external IPv4 network.

Configuring NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example, the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to an IPv4 address in the range 172.20.120.200 to 172.20.120.210.

Enter the following command to enable NAT64:

```
config system nat64
   set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix from the well-known prefix of 64:ff9b::/96 and setting `always-synthesize-aaaa-record` to `enable` (default), the DNS proxy does not check for AAAA records but rather synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
   set status enable
```

```
    set nat64-prefix 64:ff9b::/96
    set always-synthesize-aaaa-record enable
end
```

Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
    edit internal-net6
        set ip6 2001:db8:1::/48
    end
```

Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
    edit external-net4
        set subnet 172.20.120.0/24
        set associated-interface wan1
    end
```

Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
    edit exit-pool4
        set startip 172.20.120.200
        set endip 172.20.120.210
    end
```

Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
    config firewall policy64
        edit 0
            set srcintf internal
            set srcaddr internal-net6
            set dstintf wan1
            set dstaddr external-net4
            set action accept
            set schedule always
            set service ANY
            set logtraffic enable
            set ippool enable
            set poolname exit-pool4
        end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, which can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

How a host on the internal IPv6 network communicates with example.server.com that only has IPv4 address on the Internet

1. The host on the internal network does a DNS lookup for example.server.com by sending a DNS query for an AAAA record for example.server.com.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for example.server.com.

4. The previous step is skipped if `always-synthesize-aaaa-record` is enabled.
5. The DNS proxy performs an A-record query for example.server.com and gets back an RRSet containing a single A record with the IPv4 address 172.20.120.12.
6. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is 64:ff9b::172.20.120.12.
7. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address 64:ff9b::172.20.120.12.
8. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
9. The FortiGate unit translates the destination address of the packets from IPv6 address 64:ff9b::172.20.120.12 to IPv4 address 172.20.120.12 and translates the source address of the packets to 172.20.120.200 (or another address in the IP pool range) and forwards the packets out the wan1 interface to the Internet.

NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy from the CLI. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT:

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr internal_net
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
   end
```

Its also can be useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
config firewall ippool6
   edit example_6_pool
      set startip 2001:db8::
      set endip 2001:db8::
   end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
config firewall address6
   edit device_address
      set ip6 2001:db8::132/128
```

```
    end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr device_address
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
      set ippool enable
      set poolname example_6_pool
   end
```

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps the destination address 2001:db8::dd to 2001:db8::ee.

```
config firewall vip6
   edit example-vip6
      set extip 2001:db8::dd
      set mappedip 2001:db8::ee
   end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee.

```
config firewall policy6
   edit 0
      set srcintf internal
      set dstintf wan1
      set srcaddr all
      set dstaddr example-vip6
      set action accept
      set schedule always
      set service ANY
   end
```

NAT64 and NAT66 session failover

The FortiGate Clustering Protocol (FGCP) supports IPv6, NAT64, and NAT66 session failover. If session pickup is enabled, these sessions are synchronized between cluster members and, after an HA failover, the sessions will resume with only minimal interruption.

NAT46

NAT46 is used to translate IPv4 addresses to IPv6 addresses so that a client on an IPv4 network can communicate transparently with a server on an IPv6 network.

To enable NAT46, use the following CLI command:

```
config firewall vip46
```

NAT46 policies

Security policies for NAT46 can be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using **Feature Select**. You can then configure the policies under **Policy & Objects > Policy > NAT46**.

NAT46 policies and can also be configured from the CLI using the following command:

```
config firewall policy46
```

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in RFC 4443.

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It is also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.
- ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).
- ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

- Destination Unreachable
- Time Exceeded
- Packet Too Big
- Parameter Problems
- Information messages are divided into three groups:
- Diagnostic messages
- Neighbor Discovery messages
- Messages for the management of multicast groups.

ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 − 127 are error messages and type codes 128 − 255 are for information messages.

ICMPv6 Types and Codes

Type #	Type Name	Code
0	Reserved	0 - no route to destination 1 - communication with destination administratively prohibited 2 - beyond scope of source address 3 - address unreachable 4 - port unreachable 5 - source address failed ingress/egress policy 6 - reject route to destination 7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit 1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered 1 - unrecognized Next Header type encountered 2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	
128	Echo Request	
129	Echo Replay	
130	Multicast Listener Query	
131	Multicast Listener Report	

Type #	Type Name	Code
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command 1 - Router Renumbering Result 255 - Sequence Number Reset
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query. 1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP. 2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	

Type #	Type Name	Code
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in **System > Config > Features**. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Dual stack routing

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses.

In FortiOS, dual stack architecture it is not comprised merely of basic addressing functions that operate in both versions of IP. The other features of the appliance, such as UTM and routing, can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunnelling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

IPv6 tunnelling

IPv6 Tunnelling is the act of tunnelling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. Unlike NAT, once the packet reaches its final destination, the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network.

The key to IPv6 tunnelling is the ability of the two devices to be dual stack compatible in order to work with both IPv4 and IPv6 at the same time. In the process, the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet, removes the IPv4 header, updates the IPv6 header, and processes the packet.

There are two types of tunnels in IPv6:

Automatic tunnels: Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunnelled to.

Configured tunnels: Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel configuration

There are a few ways in which the tunnelling can be performed depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Host to Host: Dual Stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.

Network Device to Host: Dual Stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

The node that does the encapsulation needs to maintain soft state information about each tunnel in order to process the IPv6 packets.

Use the following command to tunnel IPv6 traffic over an IPv4 network. The IPv6 interface is configured under `config system interface`. The command to do the reverse is `config system ipv6-tunnel`. These commands are not available in Transparent mode.

```
config system sit-tunnel
   edit <tunnel name>
      set destination <tunnel _address>
      set interface <name>
      set ip6 <address_ipv6>
      set source <address_ipv4>
   end
```

Variable	Description	Default
`edit <tunnel_name>`	Enter a name for the IPv6 tunnel.	No default.
`destination <tunnel_ address>`	The destination IPv4 address for this tunnel.	0.0.0.0
`interface <name>`	The interface used to send and receive traffic for this tunnel.	No default.
`ip6 <address_ipv6>`	The IPv6 address for this tunnel.	No default.
`source <address_ipv4>`	The source IPv4 address for this tunnel.	0.0.0.0

Tunnelling IPv6 through IPsec VPN

A variation on tunnelling IPv6 through IPv4 is to use an IPsec VPN tunnel between two FortiGate devices. FortiOS supports IPv6 over IPsec. In this sort of scenario, two networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPsec VPN tunnel is created between the FortiGate units and a tunnel is created over the IPv4-based Internet, but the traffic in the tunnel is IPv6. This has the additional advantage of securing the traffic.

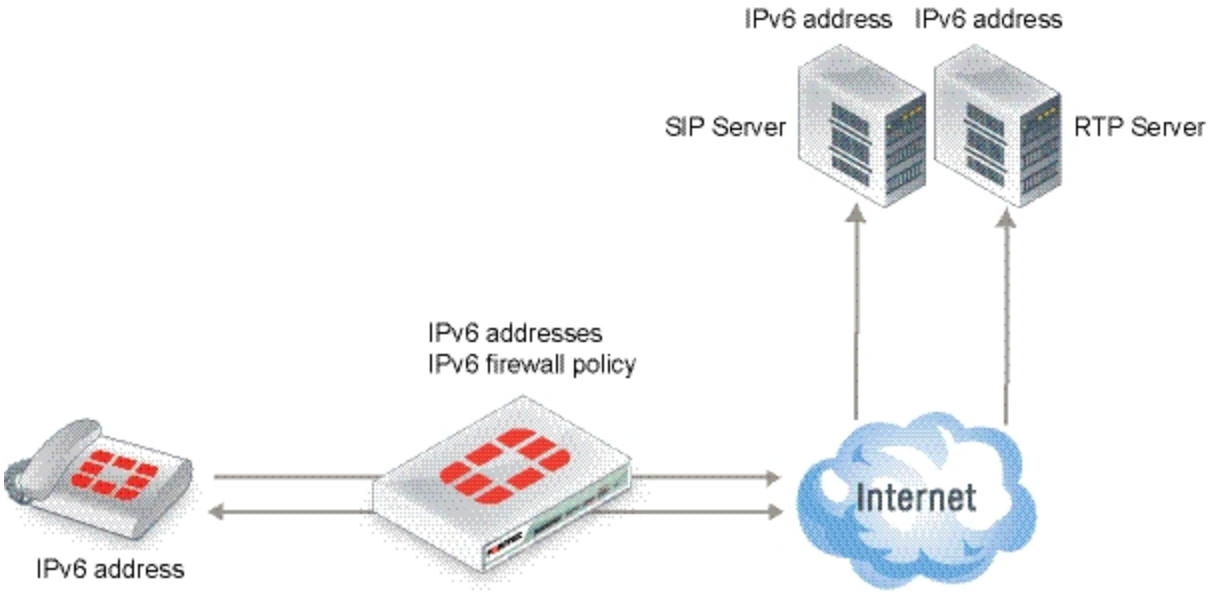
For configuration information, see IPv6 IPsec VPN on page 1813.

SIP over IPv6

FortiOS supports Sessions Initiate Protocol (SIP) over IPv6. The SIP application-level gateway (ALG) can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown below, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.



To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIB entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:

```
fgSysSes6Count
fgSysSes6Rate1
fgSysSes6Rate10
fgSysSes6Rate30
fgSysSes6Rate60
```

- IPv6 Policy Statistics:

```
fgFwPol6StatsTable
fgFwPol6StatsEntry
FgFwPol6StatsEntry
fgFwPol6ID
fgFwPol6PktCount
fgFwPol6ByteCount
```

- IPv6 Session Statistics:

```
fgIp6SessStatsTable
fgIp6SessStatsEntry
FgIp6SessStatsEntry
fgIp6SessNumber
```

The fgSysSesCount and fgSysSesRateX MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

New OIDs

The following OIDs have been added:

```
FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo
.fgSysSes6Count   1.3.6.1.4.1.12356.101.4.1.15
.fgSysSesRate1    1.3.6.1.4.1.12356.101.4.1.16
.fgSysSesRate10   1.3.6.1.4.1.12356.101.4.1.17
.fgSysSesRate30   1.3.6.1.4.1.12356.101.4.1.18
.fgSysSesRate60   1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID   1.3.6.1.4.1.12356.101.5.1.2.2.1.1
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount   1.3.6.1.4.1.12356.101.5.1.2.2.1.
    2
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount   1.3.6.1.4.1.12356.101.5.1.2.2.1
    .3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProtoTables
.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber 1.3.6.1.4.1.12356.101.11.2.3.1.1
```

EXAMPLE SNMP get/walk output

```
// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4

FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89
```

IPv6 Per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```
config firewall policy6
   edit 0
      set per-ip-shaper "new-perip-shaper"
   end
```

DHCPv6

You can use DHCP with IPv6 using the CLI. To configure DHCP, ensure IPv6 is enabled by going to **System > Config > Features** and enabling **IPv6**.

Use the CLI command

```
config system dhcp6
```

For more information on the configuration options, see the FortiGate CLI Reference.

DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back. The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
   edit internal
      config ipv6
         set dhcp6-relay-service enable
         set dhcp6-relay-type regular
         set dhcp6-relay-ip 2001:db8:0:2::30
      end
```

IPv6 forwarding

Policies, IPS, Application Control, flow-based antivirus, web filtering, and DLP

FortiOS fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, virus scanning, and web filtering.
To add flow-based inspection to IPv6 traffic go to **Policy & Objects > Policy > IPv6** and select **Create New** to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Under **Security Profiles**, select the profiles to apply to the traffic.

Obtaining IPv6 addresses from an IPv6 DHCP server

From the CLI, you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
   edit wan2
      config ipv6
         set ip6-mode dhcp
      end
```

IPv6 Configuration

This section contains configuration information for IPv6 on FortiOS. Attempts are made to include scenarios in each section to better assist with the configuration and to orient the information toward a particular task.

You will find information on the following:

IPv6 address groups
IPv6 address ranges
IPv6 firewall addresses
ICMPv6
IPv6 IPsec VPN
TCP MSS values
BGP and IPv6
RIPng — RIP and IPv6
IPv6 RSSO support
IPv6 IPS
Blocking IPv6 packets by extension headers
IPv6 Denial of Service policies
Configure hosts in an SNMP v1/2c community to send queries or receive traps
IPv6 PIM sparse mode multicast routing

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Config > Features**.
2. Select **IPv6** and click **Apply**.

IPv6 address groups

To create IPv6 address groups from existing IPv6 addresses - web-based manager

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address Group.**
2. Select **IPv6 Group**, and fill out the fields with the following information:

Group Name	Web_Server_Cluster

Members	Web_Server-1
	Web_Server-2
	Web_Server-3

3. Select **OK.**

To create IPv6 address groups from existing IPv6 addresses - CLI

```
config firewall addrgrp6
   edit Web_Server_Cluster
      set member Web_Server-1 Web_Server-2 Web_Server-3
   end
```

To verify that the addresses were added correctly

1. Go to **Policy & Objects > Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. From the CLI, enter the following commands:

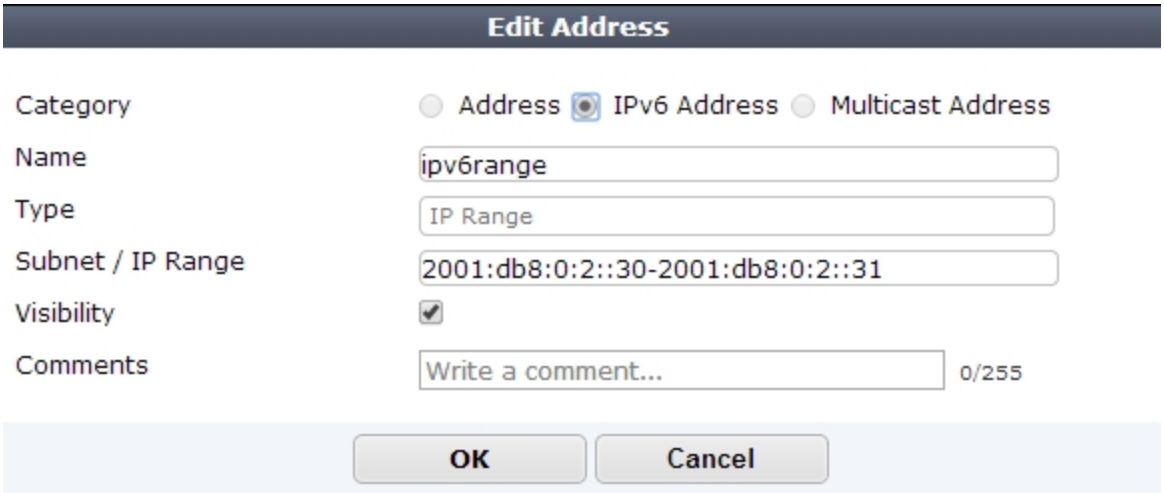
```
config firewall addgrp6
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

IPv6 address ranges

You can configure IPv6 address ranges in both the GUI and the CLI.

To configure IPv6 address ranges - web-based manager:

1. Go to **Policy & Objects > Objects > Addresses.**
2. Set the **Type** to **IP Range** and enter the IPv6 addresses as shown:



To configure IPv6 address ranges - CLI:

```
config firewall address6
   edit ipv6range
```

```
    set type iprange
    set start-ip 2001:db8:0:2::30
    set end-ip 2001:db8:0:2::31
end
```

IPv6 firewall addresses

Scenario: Mail Server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network. This server is on the network off of port1.

- The IP address is 2001:db8:0:2::20/128
- There should be a tag for this address being for a server.

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address.**
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Mail_Server
Type	Subnet
IPv6 Address	2001:db8:0:2::20/128

3. Select **OK.**

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
   edit Mail_Server
      set type ipprefix
      set subnet 2001:db8:0:2::20/128
   end
```

Scenario: First Floor Network

You need to create an IPv6 address for the subnet of the internal network off of Port1. These computers connect to port1. The network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx

There should be a reference to this being the network for the 1st floor of the building.

1. Go to **Policy & Objects > Objects > Addresses**
2. Select **Create New > Address.**Select **IPv6 Address** and fill out the fields with the following information:

Name	Internal_Subnet_1
Type	Subnet / IP Range

IPv6 Address	2001:db8:0:2::/64
Comments	Network for 1st Floor

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall address6
   edit Internal_Subnet_1
      set comment "Network for 1st Floor"
      set type ipprefix
      set subnet 2001:db8:0:2::/64
   end
```

Scenario: Accounting Team

You need to create an IPv6 address for the Accounting Team that's on the 1st Floor. These users are off of various ports of the FortiGate, but they have all been assigned addresses between 2001:db8:0:2::2000 and 2001:db8:0:2::a000

Configuring the Example using the GUI

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New > Address.**
2. Select **IPv6 Address** and fill out the fields with the following information

Name	Accounting_Team
Type	IP Range
Subnet / IP Range	2001:db8:0:2::2000-2001:db8:0:2::a000

3. Select **OK.**

Configuring the Example using the CLI

Enter the following CLI command:

```
config firewall address6
   edit Accounting_Team
      set type iprange
      set visibility enable
      set start-ip 2001:db8:0:2::2000
      set end-ip 2001:db8:0:2::a000
      end
```

To verify that the addresses were added correctly:

1. Go to **Policy & Objects > Objects > Addresses.** Check that the addresses have been added to the address list and that they are correct.
2. Enter the following CLI command:

```
config firewall address6
   edit <the name of the address that you wish to verify>
      Show full-configuration
```

ICMPv6

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

To configure ICMPv6 - web-based manager:

1. Go to **Policy & Objects > Objects > Services** and select **Create New > Service**.
2. Fill out the fields with the following information

Name	diagnostic-test1
Service Type	Firewall
Show in Service List	Enabled
Category	Uncategorized
Protocol Type	ICMP6
Type	140

3. Select **OK.**
4. Enter the following CLI command:

```
config firewall service custom
   edit diagnostic-test1
      set protocol ICMP6
      set icmptype 140
      set icmpcode 0
      set visibility enable
   end
```

To verify that the category was added correctly:

1. Go to **Policy & Objects > Objects > Services.**Check that the services have been added to the services list and that they are correct.
2. Enter the following CLI command:

```
config firewall service custom
   edit <the name of the service that you wish to verify>
      show full-configuration
```

IPv6 IPsec VPN

This chapter describes how to configure your FortiGate unit's IPv6 IPsec VPN functionality.

By default IPv6 configurations do not appear in the web-based manager. You need to enable the feature first.

To enable IPv6:

1. Go to **System > Config > Features**.
2. Select **IPv6** and click **Apply**.

The topics in this section include:

- Overview of IPv6 IPsec support
- Configuring IPv6 IPsec VPNs
- Site-to-site IPv6 over IPv6 VPN example
- Site-to-site IPv4 over IPv6 VPN example
- Site-to-site IPv6 over IPv4 VPN example

Overview of IPv6 IPsec support

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes how IPv6 IPsec support differs from IPv4 IPsec support.

Where both the gateways and the protected networks use IPv6 addresses, sometimes called IPv6 over IPv6, you can create either an auto-keyed or manually-keyed VPN. You can also combine IPv6 and IPv4 addressing in an auto-keyed VPN in the following ways:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors.

Compared with IPv4 IPsec VPN functionality, there are some limitations:

- Except for IPv6 over IPv4, remote gateways with Dynamic DNS are not supported.
- Selectors cannot be firewall address names. Only IP address, address range and subnet are supported.
- Redundant IPv6 tunnels are not supported.

Certificates

On a VPN with IPv6 phase 1 configuration, you can authenticate using VPN certificates in which the common name (cn) is an IPv6 address. The `cn-type` keyword of the `user peer` command has an option, `ipv6`, to support this.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN: phase 1 settings, phase 2 settings, security policies, and routing.

Phase 1 configuration

In the web-based manager, you define the Phase 1 as IPv6 in the Advanced settings. Enable the IPv6 Version check box. You can then enter an IPv6 address for the remote gateway.

In the CLI, you define an IPsec phase 1 configuration as IPv6 by setting `ip-version` to `6`. Its default value is `4`. Then, the `local-gw` and `remote-gw` keywords are hidden and the corresponding `local-gw6` and `remote-gw6` keywords are available. The values for `local-gw6` and `remote-gw6` must be IPv6 addresses. For example:

```
config vpn ipsec phase1-interface
   edit tunnel6
      set ip-version 6
      set remote-gw6 0:123:4567::1234
      set interface port3
      set proposal 3des-md5
   end
```

Phase 2 configuration

To create an IPv6 IPsec phase 2 configuration in the web-based manager, you need to define IPv6 selectors in the Advanced settings. Change the default “0.0.0.0/0” address for Source address and Destination address to the IPv6 value “::/0”. If needed, enter specific IPv6 addresses, address ranges or subnet addresses in these fields.

In the CLI, set `src-addr-type` and `dst-addr-type` to `ip6`, `range6` or `subnet6` to specify IPv6 selectors. By default, zero selectors are entered, “::/0” for the `subnet6` address type, for example. The simplest IPv6 phase 2 configuration looks like this:

```
config vpn ipsec phase2-interface
   edit tunnel6_p2
      set phase1name tunnel6
      set proposal 3des-md5
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Security policies

To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network’s port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6.

Routing

Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them. You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You also need a route to the remote protected network via the IPsec interface.

To create a static route - web-based manager:

1. Go to **Router > Static > Static Routes**.

On some desktop FortiGate models, go to **System > Network > Routing**.

2. Select the drop-down arrow on the **Create New** button and select **IPv6 Route**.
3. Enter the information and select **OK**.

To create a static route - CLI:

1. In the CLI, use the `router static6` command. For example, where the remote network is `fec0:0000:0000:0004::/64` and the IPsec interface is `toB`:

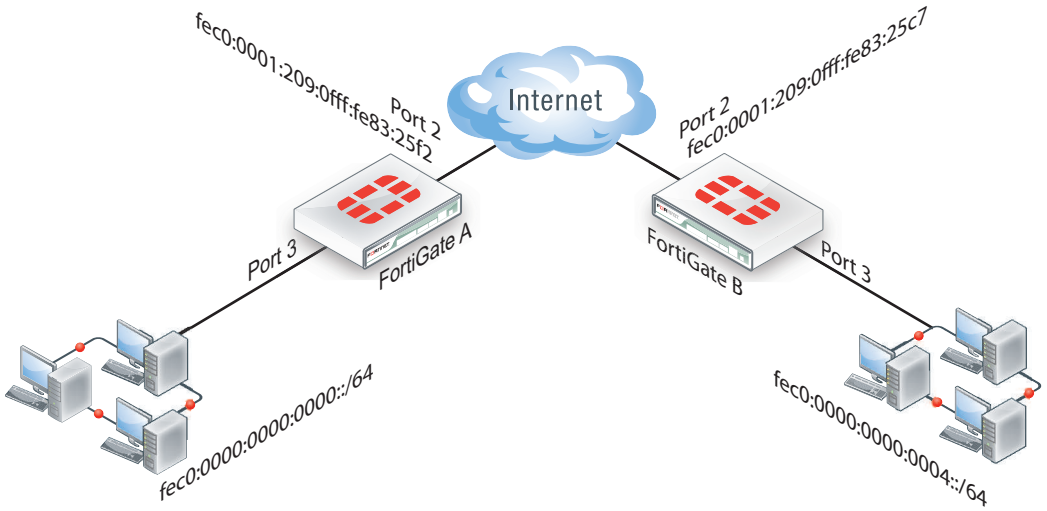
```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   next
end
```

If the VPN is IPV4 over IPv6, the route to the remote protected network is an IPv4 route. If the VPN is IPv6 over IPv4, the route to the remote VPN gateway is an IPv4 route.

Site-to-site IPv6 over IPv6 VPN example

In this example, computers on IPv6-addressed private networks communicate securely over public IPv6 infrastructure.

Example IPv6-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the public network and port 3 connects to the local network.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
```

```
      end
    next
    edit port3
      config ipv6
        set ip6-address fec0::0000:209:0fff:fe83:25f3/64
      end
    next
end
```

Configure FortiGate A IPsec settings

The phase 1 configuration creates a virtual IPsec interface on port 2 and sets the remote gateway to the public IP address FortiGate B. This configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address.

```
config vpn ipsec phase1-interface
  edit toB
    set ip-version 6
    set interface port2
    set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
    set dpd enable
    set psksecret maryhadalittlelamb
    set proposal 3des-md5 3des-sha1
  end
```

By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
  edit toB2
    set phase1name toB
    set proposal 3des-md5 3des-sha1
    set pfs enable
    set replay enable
    set src-addr-type subnet6
    set dst-addr-type subnet6
  end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. The address `all6` must be defined using the `firewall address6` command as `::/0`.

```
config firewall policy6
  edit 1
    set srcintf port3
    set dstintf toB
    set srcaddr all6
    set dstaddr all6
    set action accept
    set service ANY
    set schedule always
  next
  edit 2
    set srcintf toB
    set dstintf port3
    set srcaddr all6
```

```
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB. A default route sends all IPv6 traffic out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. Security policies enable traffic to pass between the private network and the IPsec interface. Routing ensures traffic for the private network behind FortiGate A goes through the VPN and that all IPv6 packets are routed to the public network.

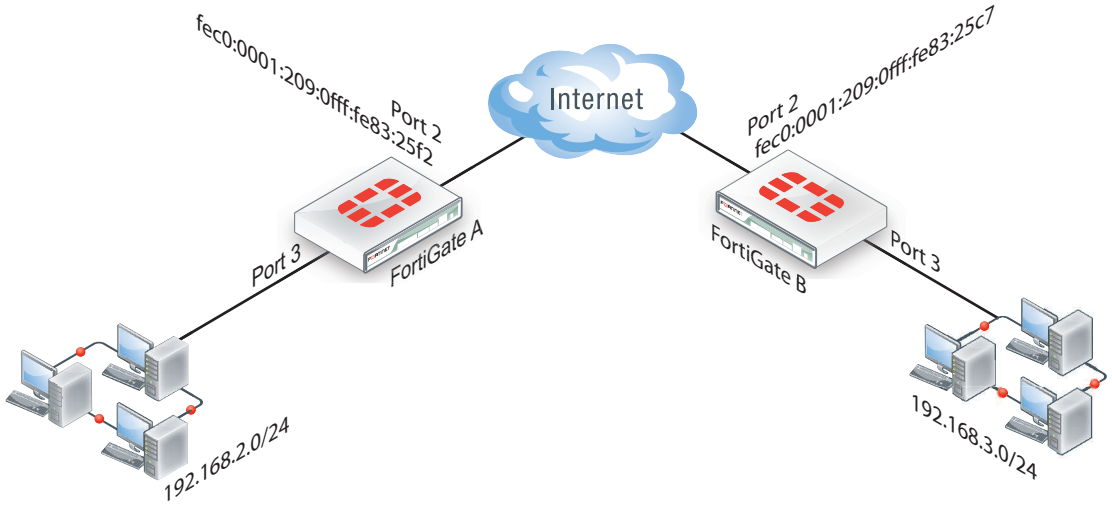
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:209:0fff:fe83:25c7/64
      end
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toA
      set dst fec0:0000:0000:0000::/64
end
```

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

Example IPv4-over-IPv6 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv6 public network and port 3 connects to the IPv4 LAN.

```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0001:209:0fff:fe83:25f2/64
      end
   next
   edit port3
      set 192.168.2.1/24
   end
```

Configure FortiGate A IPsec settings

The phase 1 configuration is the same as in the IPv6 over IPv6 example.

```
config vpn ipsec phase1-interface
   edit toB
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0003:209:0fff:fe83:25c7
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The phase 2 configuration is the same as you would use for an IPv4 VPN. By default, phase 2 selectors are set to accept all subnet addresses for source and destination.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
```

Configure FortiGate A security policies

Security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. These are IPv4 security policies.

```
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all
      set dstaddr all
      set action accept
      set service ANY
      set schedule always
```

```
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv4 static route. A default route sends all IPv6 traffic, including the IPv6 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device port2
      set dst 0::/0
   next
   edit 2
      set device toB
      set dst 192.168.3.0/24
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the public IP address of FortiGate A. The IPsec phase 2 configuration has IPv4 selectors.

IPv4 security policies enable traffic to pass between the private network and the IPsec interface. An IPv4 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv6 static route ensures that all IPv6 packets are routed to the public network.

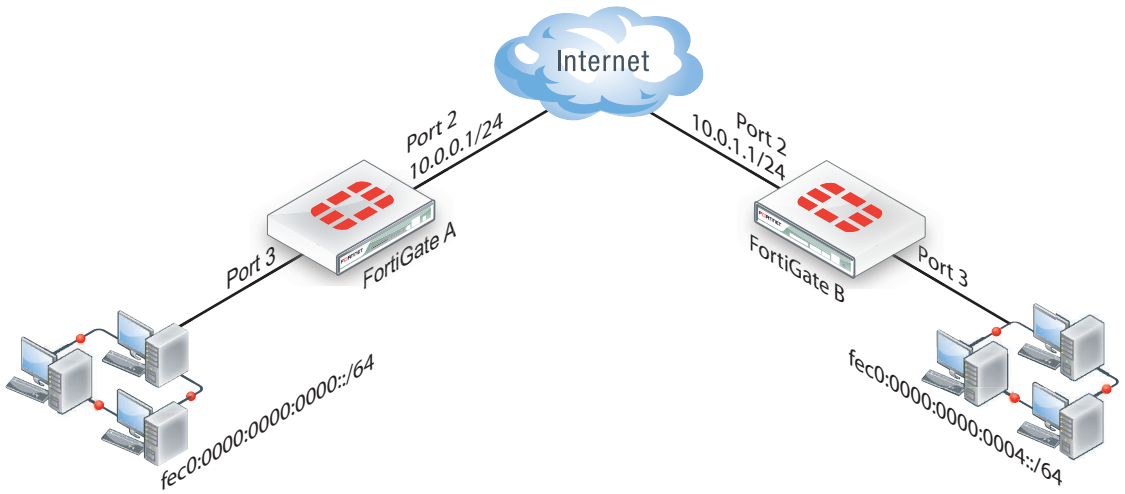
```
config system interface
   edit port2
      config ipv6
         set ip6-address fec0::0003:fe83:25c7/64
      end
   next
   edit port3
      set 192.168.3.1/24
   end
config vpn ipsec phase1-interface
   edit toA
      set ip-version 6
      set interface port2
      set remote-gw6 fec0:0000:0000:0001:209:0fff:fe83:25f2
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
   end
config firewall policy
   edit 1
      set srcintf port3
      set dstintf toA
```

```
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    next
    edit 2
        set srcintf toA
        set dstintf port3
        set srcaddr all
        set dstaddr all
        set action accept
        set service ANY
        set schedule always
    end
config router static6
    edit 1
        set device port2
        set dst 0::/0
    next
    edit 2
        set device toA
        set dst 192.168.2.0/24
    end
```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed private networks communicate securely over IPv4 public infrastructure.

Example IPv6-over-IPv4 VPN topology



Configure FortiGate A interfaces

Port 2 connects to the IPv4 public network and port 3 connects to the IPv6 LAN.

```
config system interface
    edit port2
        set 10.0.0.1/24
        next
```

```
edit port3
config ipv6
   set ip6-address fec0::0001:209:0fff:fe83:25f3/64
end
```

Configure FortiGate A IPsec settings

The phase 1 configuration uses IPv4 addressing.

```
config vpn ipsec phase1-interface
   edit toB
      set interface port2
      set remote-gw 10.0.1.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
```

The phase 2 configuration uses IPv6 selectors. By default, phase 2 selectors are set to accept all subnet addresses for source and destination. The default setting for `src-addr-type` and `dst-addr-type` is `subnet`. The IPv6 equivalent is `subnet6`. The default subnet addresses are 0.0.0.0/0 for IPv4, `::/0` for IPv6.

```
config vpn ipsec phase2-interface
   edit toB2
      set phase1name toB
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
```

Configure FortiGate A security policies

IPv6 security policies are required to allow traffic between port3 and the IPsec interface toB in each direction. Define the address `all6` using the `firewall address6` command as `::/0`.

```
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toB
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toB
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
```

Configure FortiGate A routing

This simple example requires just two static routes. Traffic to the protected network behind FortiGate B is routed via the virtual IPsec interface toB using an IPv6 static route. A default route sends all IPv4 traffic, including the IPv4 IPsec packets, out on port2.

```
config router static6
   edit 1
      set device toB
      set dst fec0:0000:0000:0004::/64
   end
config router static
   edit 1
      set device port2
      set dst 0.0.0.0/0
      set gateway 10.0.0.254
   end
```

Configure FortiGate B

The configuration of FortiGate B is very similar to that of FortiGate A. A virtual IPsec interface toA is configured on port2 and its remote gateway is the IPv4 public IP address of FortiGate A. The IPsec phase 2 configuration has IPv6 selectors.

IPv6 security policies enable traffic to pass between the private network and the IPsec interface. An IPv6 static route ensures traffic for the private network behind FortiGate A goes through the VPN and an IPv4 static route ensures that all IPv4 packets are routed to the public network.

```
config system interface
   edit port2
      set 10.0.1.1/24
   next
   edit port3
      config ipv6
         set ip6-address fec0::0004:209:0fff:fe83:2569/64
      end
config vpn ipsec phase1-interface
   edit toA
      set interface port2
      set remote-gw 10.0.0.1
      set dpd enable
      set psksecret maryhadalittlelamb
      set proposal 3des-md5 3des-sha1
   end
config vpn ipsec phase2-interface
   edit toA2
      set phase1name toA
      set proposal 3des-md5 3des-sha1
      set pfs enable
      set replay enable
      set src-addr-type subnet6
      set dst-addr-type subnet6
   end
config firewall policy6
   edit 1
      set srcintf port3
      set dstintf toA
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   next
   edit 2
      set srcintf toA
      set dstintf port3
      set srcaddr all6
      set dstaddr all6
      set action accept
      set service ANY
      set schedule always
   end
config router static6
   edit 1
      set device toA
```

```
      set dst fec0:0000:0000:0000::/64
   end
config router static
   edit 1
      set device port2
      set gateway 10.0.1.254
   end
```

TCP MSS values

TCP MSS values, which control the maximum amount of data that can be sent in a single packet, can be set for IPv6 policies (for both the sender and the receiver). You can configure TCP MSS values in IPv6 using the following CLI commands:

```
config firewall policy6
   edit <index_int>
      set tcp-mss-sender <value>
      set tcp-mss-receiver <value>
   end
```

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

IPv6 BGP commands include:

```
config router bgp
   set activate6 {enable | disable}
   set allowas-in6 <max_num_AS_integer>
   set allowas-in-enable6 {enable | disable}
   set as-override6 {enable | disable}
   set attribute-unchanged6 [as-path] [med] [next-hop]
   set capability-default-originate6 {enable | disable}
   set capability-graceful-restart6 {enable | disable}
   set default-originate-route-map6 <routemap_str>
   set distribute-list-in6 <access-list-name_str>
   set distribute-list-out6 <access-list-name_str>
   set filter-list-in6 <aspath-list-name_str>
   set filter-list-out6 <aspath-list-name_str>
   set maximum-prefix6 <prefix_integer>
   set maximum-prefix-threshold6 <percentage_integer>
   set maximum-prefix-warning-only6 {enable | disable}
   set next-hop-self6 {enable | disable}
   set prefix-list-in6 <prefix-list-name_str>
   set prefix-list-out6 <prefix-list-name_str>
   set remove-private-as6 {enable | disable}
   set route-map-in6 <routemap-name_str>
   set route-map-out6 <routemap-name_str>
   set route-reflector-client6 {enable | disable}
   set route-server-client6 {enable | disable}
   set send-community6 {both | disable | extended | standard}
   set soft-reconfiguration6 {enable | disable}
   set unsuppress-map6 <route-map-name_str>
```

```
    config network6
    config redistribute6
end
```

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

- Network layout and assumptions
- Configuring the FortiGate units system information
- Configuring RIPng on FortiGate units
- Configuring other network devices
- Testing the configuration
- Debugging IPv6 on RIPng

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

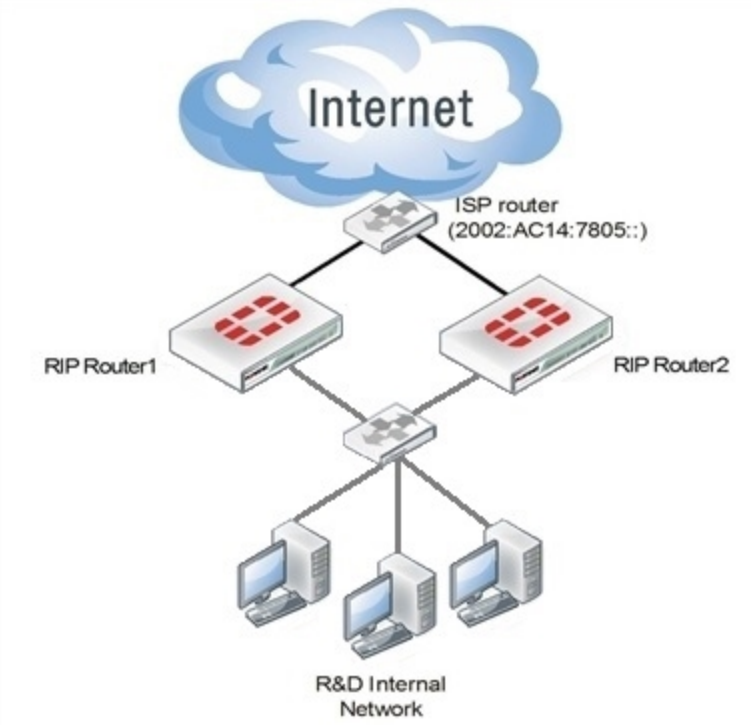
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows:

Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Network topology for the IPv6 RIPng example



Assumptions

The following assumptions have been made concerning this example:

- All FortiGate units have 5.0+ firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager:

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter “Router1”.
4. Go to **System > Config > Features**.
5. Enable **IPv6** and click **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router1 - CLI:

```
config system global
   set hostname Router1
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
         set ip6-address 2002:a0b:6565::/0
      end
   next
   edit port2
      set alias ISP
      set allowaccess https ping ssh
      set description "ISP and internet"
```

```
      config ipv6
         set ip6-address 2002:AC14:7865::
      end
   end
```

To configure system information on Router2 - web-based manager:

1. Go to **System > Dashboard > Status**.
2. For **Host name**, select **Change**.
3. Enter “Router2”.
4. Go to **System > Config > Features**.
5. Enable **IPv6** and click **Apply**.
6. Go to **System > Network > Interfaces**.
7. Edit port1 (internal) interface.
8. Set the following information, and select **OK**.

Alias	internal
IP/Netmask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select **OK**.

Alias	ISP
IP/Netmask	2002:AC14:7866::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router2 - CLI:

```
config system global
   set hostname Router2
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
         set ip6-address 2002:a0b:6566::/0
      end
```

```
next
edit port2
   set alias ISP
   set allowaccess https ping ssh
   set description "ISP and internet"
   config ipv6
      set ip6-address 2002:AC14:7866::
   end
end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI:

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6566::/0
      next
      edit 2
         set interface port2
         set ipv6 2002:AC14:7805::/0
      end
```

To configure RIPng on Router2 - CLI:

```
config router ripng
   config interface
      edit port1
      next
      edit port2
      end
   config neighbor
      edit 1
         set interface port1
         set ipv6 2002:a0b:6565::/0
      next
      edit 2
         set interface port2
```

```
    set ipv6 2002:AC14:7805::/0
end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the FortiOS Handbook Troubleshooting chapter.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

`diagnose ipv6 address list`

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

`diagnose ipv6 route list`

View ipv6 addresses that are installed in the routing table.

`get router info6 routing-table`

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

`get router info6 rip interface external`

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

`get router info6 neighbor-cache list`

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

Turn on debugging in general

Set the debug level to information, a verbose reporting level

Turn on all RIP router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

IPv6 RSSO support

RADIUS Single Sign-On (RSSO) is supported in IPv6, but can only be configured in the CLI:

```
config firewall policy6
   edit <id>
      set rsso enable
      set fall-through-unathenticated enable
   end
```

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
   edit 1
      set interface "port1"
      set srcaddr6 "all"
      set dstaddr6 "all"
      set service6 "ANY"
      set ips-sensor-status enable
      set ips-sensor "all_default"
   next
end
```

Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax:

```
config firewall ipv6-eh-filter.
```

The following commands are now available:

- `set hop-opt {disable | enable}`: Block packets with Hop-by-Hop Options header.
- `set dest-opt {disable | enable}`: Block packets with Destination Options header.
- `set hdopt-type <integer>`: Block specific Hop-by-Hop and/or Destination Option types (maximum 7 types, each between 0 and 255).
- `set routing {disable | enable}`: Block packets with Routing header.
- `set routing-type <integar>`: Block specific Routing header types (maximum 7 types, each between 0 and 255).
- `set fragment {disable | enable}`: Block packets with Fragment header.
- `set auth {disable | enable}`: Block packets with Authentication header.
- `set no-next {disable | enable}`: Block packets with No Next header.

IPv6 Denial of Service policies

Denial of Service (DoS) policies can now be configured by going to **Policy & Objects > Policy > IPv6 DoS**. For more information, refer to the “Interface Policies” section of the FortiOS Handbook Firewall chapter.

Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host. You can also configure the host for both traps and queries. You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

Use the following command to add two hosts to an SNMP community:

```
config system snmp community
   config hosts
      edit 1
         set interface port1
         set ip 172.20.120.1
         set host-type query
      end
   config hosts6
      edit 1
         set interface port6
         set ip 2001:db8:0:2::30
         set host-type trap
      end
```

IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601. You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
   set multicast-routing {enable | disable}
      config interface
         edit <interface-name>
            set hello-interval <1-65535 seconds>
            set hello-holdtime <1-65535 seconds>
      end
      config pim-sm-global
      config rp-address
         edit <index>
            set ipv6-address <ipv6-address>
      end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Chapter 16 - Life of a Packet

Life of a Packet

Directed by security policies, a FortiGate unit screens network traffic from the IP layer up through the application layer of the TCP/IP stack. This chapter provides a general, high-level description of what happens to a packet as it travels through a FortiGate unit running FortiOS 5.2.x.

This FortiOS Handbook chapter contains the following sections:

Packet flow describes the life of a packet as it passes through a FortiGate unit

Comparison of inspection types shows how different security functions map to different inspection types.

Client/Server connection packet flow example

Routing table update packet flow example

Dialup IPsec VPN with Application control example

Packet flow

After the FortiGate unit's external interface receives a packet, the packet proceeds through a number of steps on its way to the internal interface, traversing each of the inspection types, depending on the security policy and security profile configuration. The diagram below is a high level view of the packet's journey.

The description following is a high-level description of these steps as a packet enters the FortiGate unit towards its destination on the internal network. Similar steps occur for outbound traffic.

Packet flow consists of the following modules:

Ingress packet flow

- Interface TCP/IP stack
- DoS Sensor
- Interface policy
- IP integrity header checking
- IPsec VPN
- Destination NAT (DNAT)
- Routing

Stateful inspection

- Local Management Traffic
- Policy Lookup
- Session Tracking
- Session helpers
- SSL VPN
- User Authentication
- Traffic Shaping

Flow-based inspection

- IPS
- Application Control
- Web Filter
- DLP
- Antivirus

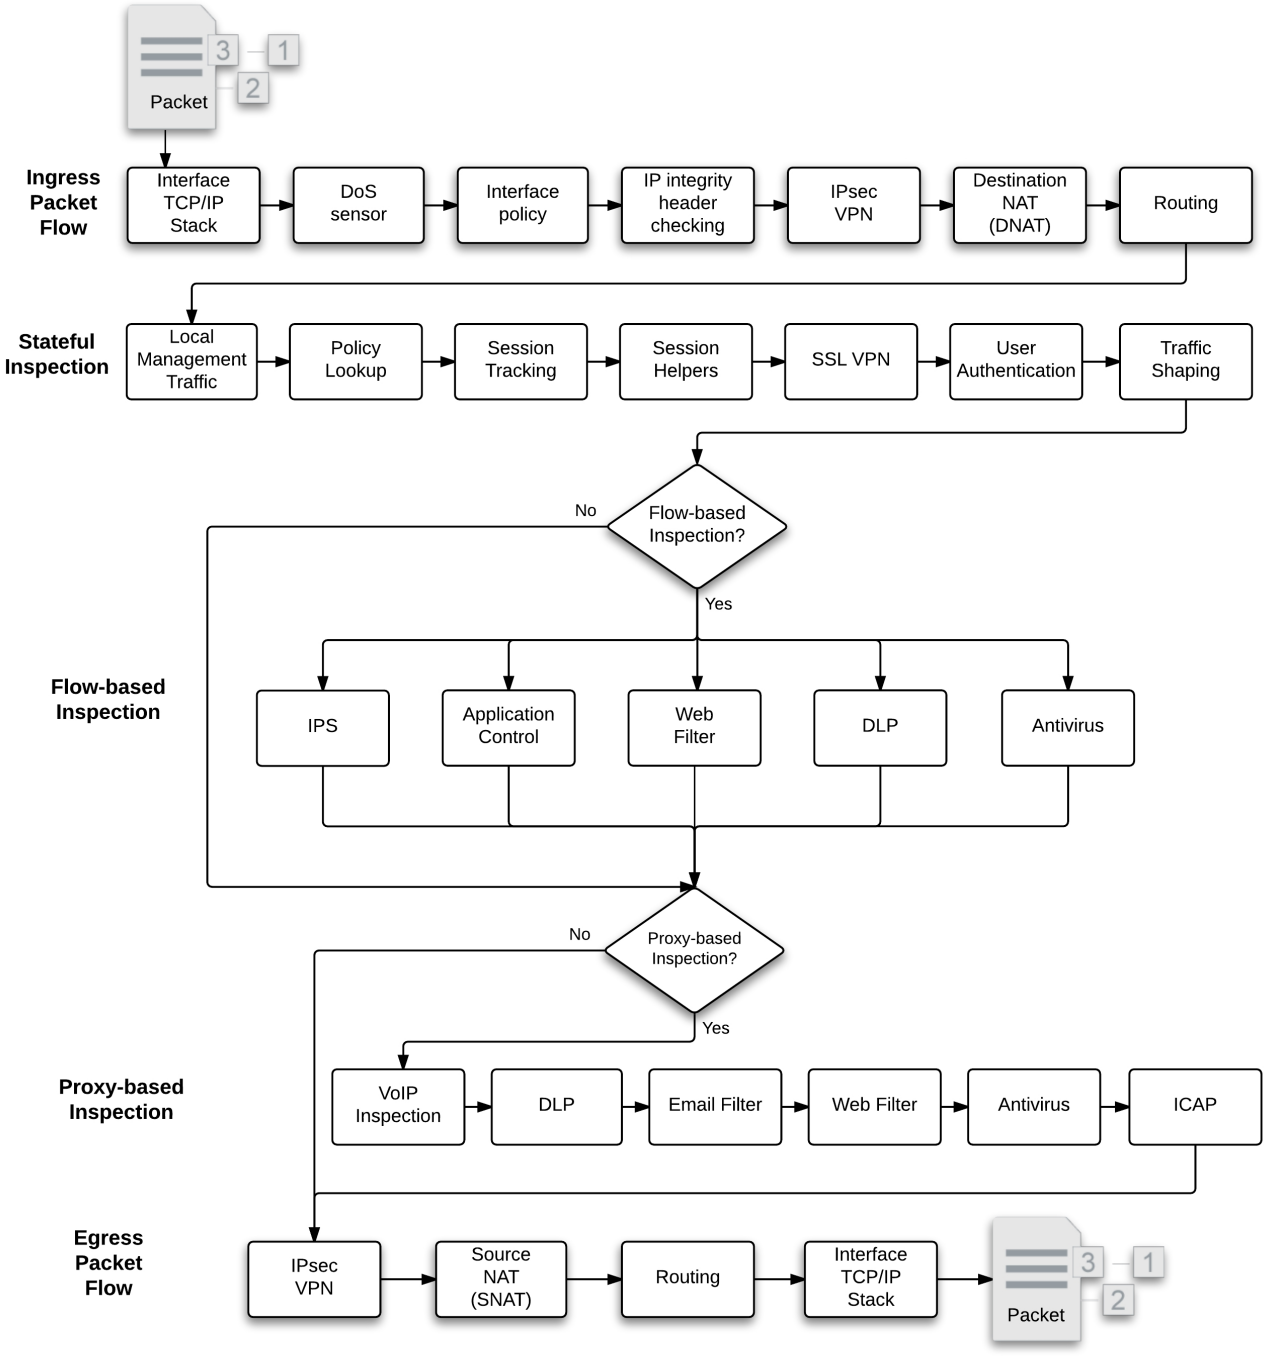
Proxy-based inspection

- VoIP Inspection
- DLP
- Email Filter
- Web Filter
- Antivirus
- ICAP

Egress packet flow

- IPsec VPN
- Source NAT (SNAT)
- Routing
- Interface TCP/IP stack

High-level Packet flow diagram



Ingress packet flow

When a packet is received by an interface and enters a FortiGate the following steps occur:

Interface TCP/IP stack

Ingress packets are received by a FortiGate interface.The packet enters the system, and the interface network device driver passes the packet to the Denial of Service (DoS) sensors, if enabled, to determine whether this is a valid information request or not.

DoS sensor

DoS scans are handled very early in the life of the packet to determine whether the traffic is valid or is part of a DoS attack.The DoS module inspects all traffic flows but only tracks packets that can be used for DoS attacks (for example, TCP SYN packets), to ensure they are within the permitted parameters. Suspected DoS attacks are blocked, other packets are allowed.

IP integrity header checking

The FortiGate unit reads the packet headers to verify if the packet is a valid TCP, UDP, ICMP, SCTP or GRE packet. The only verification that is done at this step to ensure that the protocol header is the correct length. If it is, the packet is allowed to carry on to the next step. If not, the packet is dropped.

IPsec VPN

If the packet is an IPsec packet, the IPsec engine attempts to decrypt it. If the IPsec engine can apply the correct encryption keys and decrypt the packet, the unencrypted packet is sent to the next step. Non-IPsec traffic and IPsec traffic that cannot be decrypted passes on to the next step without being affected.

Interface policy

Interface policies apply flow-based inspection to packets received at an interface before the packets are accepted by a firewall policy. Interface policies can also be applied decrypted IPsec VPN traffic. Using interface policies you can apply IPS sensors, application control and flow-based web filtering and virus scanning to traffic before it is accepted by a firewall policy. Packets can be dropped or alowed depending on the sensor or profile settings.

Destination NAT (DNAT)

The FortiGate unit checks the NAT table and determines if the destination IP address for incoming traffic must be changed using DNAT. DNAT is typically applied to traffic from the Internet that is going to be directed to a server on a network behind the FortiGate. DNAT means the actual address of the internal network is hidden from the Internet. This step determines whether a route to the destination address actually exists.

DNAT must take place before routing so that the FortiGate unit can route packets to the correct destination.

Routing

The routing step uses the routing table to determine the interface to be used by the packet as it leaves the FortiGate unit. Routing also distinguishes between local traffic and forwarded traffic. Firewall policies are matched with packets depending on the source and destination interface used by the packet. The source interface is known when the packet is received and the destination interface is determined by routing.

Stateful inspection

Stateful inspection looks at the first packet of a session and looks in the policy table to make a security decision about the entire session. Stateful inspection looks at packet TCP SYN and FIN flags to identity the start and end of a session, the source/destination IP, source/destination port and protocol. Other checks are also performed on the packet payload and sequence numbers to verify it as a valid session and that the data is not corrupted or poorly formed.

When the first packet is a session is matched in the policy table, stateful inspection adds information about the session to its session table. So when subsequent packets are received for the same session, stateful inspection can determine how to handle them by looking them up in the session table (which is more efficient than looking them up in the policy table).

Stateful inspection makes the decision to drop or allow a session and apply security features to it based on what is found in the first packet of the session. Then all subsequent packets in the same session are processed in the same way.

When the final packet in the session is processed, the session is removed from the session table. Stateful inspection also has a session idle timeout that removes sessions from the session table that have been idle for the length of the timeout.

See the Stateful Firewall Wikipedia article (https://en.wikipedia.org/wiki/Stateful_firewall) for an excellent descruption of stateful inspection.

Local management traffic

Local management traffic terminates at a FortiGate interface. This can be any FortiGate interface included dedicated management interfaces. In multiuple VDOM mode local management traffic terminates at the management interface. In Transparent mode, local management traffic terminates at the management IP address.

Local management traffic includes administrative access, some routing protocol communication, central management from FortiManager, communication with the FortiGuard network and so on. Management traffic is allowed or blocked according to the Local In Policy list which lists all management protocols and their access control settings. You configure local management access indirectly by configuring administrative access and so on.

Management traffic is processed by applications such as the web server which displays the FortiOS web-based manager, the SSH server for the CLI or the FortiGuard server to handle local FortiGuard database updates or FortiGuard Web Filtering URL lookups.

Local management traffic is not involved in subsequent stateful inspection steps.

SSL VPN traffic terminates at a FortiGate interface similar to local management traffic. However, SSL VPN traffic uses a different destination port number that administrative traffic and can thus be detected and handled differently.

Policy lookup

The first stateful inspection step is a policy lookup that matches the packet with a firewall policy based on standard firewall matching criteria (source and destination interfaces, source and destination IP addresses, and port numbers). If the policy denies the packet it is discarded. An accepted packet continues to the next step.

Many FortiOS features are applied to traffic depending on the settings in the policy that matches the traffic as determined by the policy lookup. This includes authentication, security features and so on.

Session tracking

As described above for stateful inspection. Sessions are tracked in a session table after policy lookup has identified a new session.

Session helpers

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall. FortiOS includes the following session helpers:

- PPTP
- H323
- RAS
- TNS
- TFTP
- RTSP
- FTP
- MMS
- PMAP
- SIP
- DNS-UDP
- RSH
- DCERPC
- MGCP

SSL VPN

Local SSL VPN traffic is treated like special management traffic as determined by the SSL VPN destination port. Packets are decrypted and are routed to an SSL VPN interface. Polcy lookup is then used to control how packets are forwarded to their destination outside the FortiGate.

User Authentication

User authentication added to security policies is handled by the stateful inspection, which is why Firewall authentication is based on IP address. Authentication takes place after policy lookup selects a policy that includes authentication.

Traffic Shaping

If the policy that matches the packet includes traffic shaping it is applied as the last stateful inspection step.

Flow-based inspection

Flow-based inspection identifies and blocks security threats in real time as they are identified.

Flow-based inspection samples packets in a session and uses single-pass Direct Filter Approach (DFA) pattern matching to identify possible attacks or threats. Depending on the options selected in the firewall policy that

accepted the session, flow-based inspection can apply **IPS**, **Application Control**, **Web Filtering**, **DLP** and **Antivirus**.

All of the applicable flow-based security modules are applied simultaneously in one pass. IPS, Application Control, Web Filtering and DLP filtering happen together. Flow-based antivirus caches files during protocol decoding and submits cached files for virus scanning while the other matching is carried out.

Flow inspection typically requires less processing resources than proxy inspection and since its not a proxy, flow-based inspection does not change packets (unless a threat is found and packets are blocked). Flow-based inspection cannot apply as many features as proxy inspection (for example, flow-based inspection does not support client comforting and some aspects of replacement messages).

IPS and Application Control are only applied using flow-based inspection. Web Filtering, DLP and Antivirus can also be applied using proxy-based inspection.

Proxy-based inspection

Proxy-based inspection uses a proxy to inspect content traffic (VoIP, HTTP, HTTPS, FTP, email, and others) for threats. The proxy extracts and caches content, such as files and web pages, from a content session and inspects the cached content for threats. Content inspection happens in the following order: **VoIP inspection**, **DLP**, **Email Filtering**, **Web Filtering**, **Antivirus**, and **ICAP**. If no threat is found the proxy relays the content to its destination. If a threat is found the proxy can block the content and replace it with a replacement message.

The proxy can also block VoIP traffic that contains threats. VoIP inspection can also look inside VoIP packets and extract port and address information and open pinholes in the firewall to allow VoIP traffic through.

ICAP intercepts HTTP and HTTPS traffic and forwards it to an ICAP server. The FortiGate unit is the surrogate, or “middle-man”, and carries the ICAP responses from the ICAP server to the ICAP client; the ICAP client then responds back, and the FortiGate unit determines the action that should be taken with these ICAP responses and requests.

Egress packet flow

After stateful inspection and flow or proxy-based inspection the packet goes through the following steps before exiting.

IPsec VPN

If the packet is to be sent out an IPsec tunnel, it is at this stage the encryption and required encapsulation is performed.

Source NAT (SNAT)

The FortiGate unit checks the NAT table and determines if the source IP address for outgoing traffic must be changed using SNAT. SNAT is typically applied to traffic from an internal netwotk heading out to the Internet. SNAT means the actual address of the internal network is hidden from the Internet.

DNAT must take place before routing so that the FortiGate unit can route the packet to the correct destination.

Routing

The final routing step determines the next hop router to send the packet to after it exits the FortiGate unit.

Interface TCP/IP Stack

Egress packets are received by the interface network device driver which forwards the packet out the interface an onto the network.

Comparison of inspection types

The tables in this section show how different security functions map to different inspection types.

Mapping security functions to inspection types

The table below lists FortiOS security functions and shows whether they are applied during stateful inspection, flow-based inspection or proxy-based inspection.

FortiOS security functions and inspection types

Security Function	Stateful Inspection	Flow-based inspection	Proxy-based inspection
Firewall	yes		
IPsec VPN	yes		
Traffic Shaping	yes		
User Authentication	yes		
Management Traffic	yes		
SSL VPN	yes		
IPS		yes	
Antivirus		yes	yes
Application Control		yes	
Web filtering		yes	yes
DLP		yes	yes
Email Filtering			yes
VoIP inspection			yes
ICAP			yes

More informaion about inspection methods

The three inspection methods each have their own strengths and weaknesses. The following table looks at all three methods side-by-side.

Inspection methods comparison

Feature	Stateful	Flow	Proxy
Inspection unit per session	first packet	selected packets	complete content
Memory, CPU required	low	medium	high
Level of threat protection	good	better	best
Authentication	yes		
IPsec and SSL VPN	yes		
Antivirus protection		yes	yes
Web Filtering		yes	yes
Data Leak Protection (DLP)		yes	yes
Application control		yes	
IPS		yes	
Delay in traffic	minor	no	small
Reconstruct entire content		no	yes

Client/Server connection packet flow example

The following example illustrates the flow of a packet that is part of a session between a client and a web server with authentication, FortiGuard Web Filtering and antivirus.

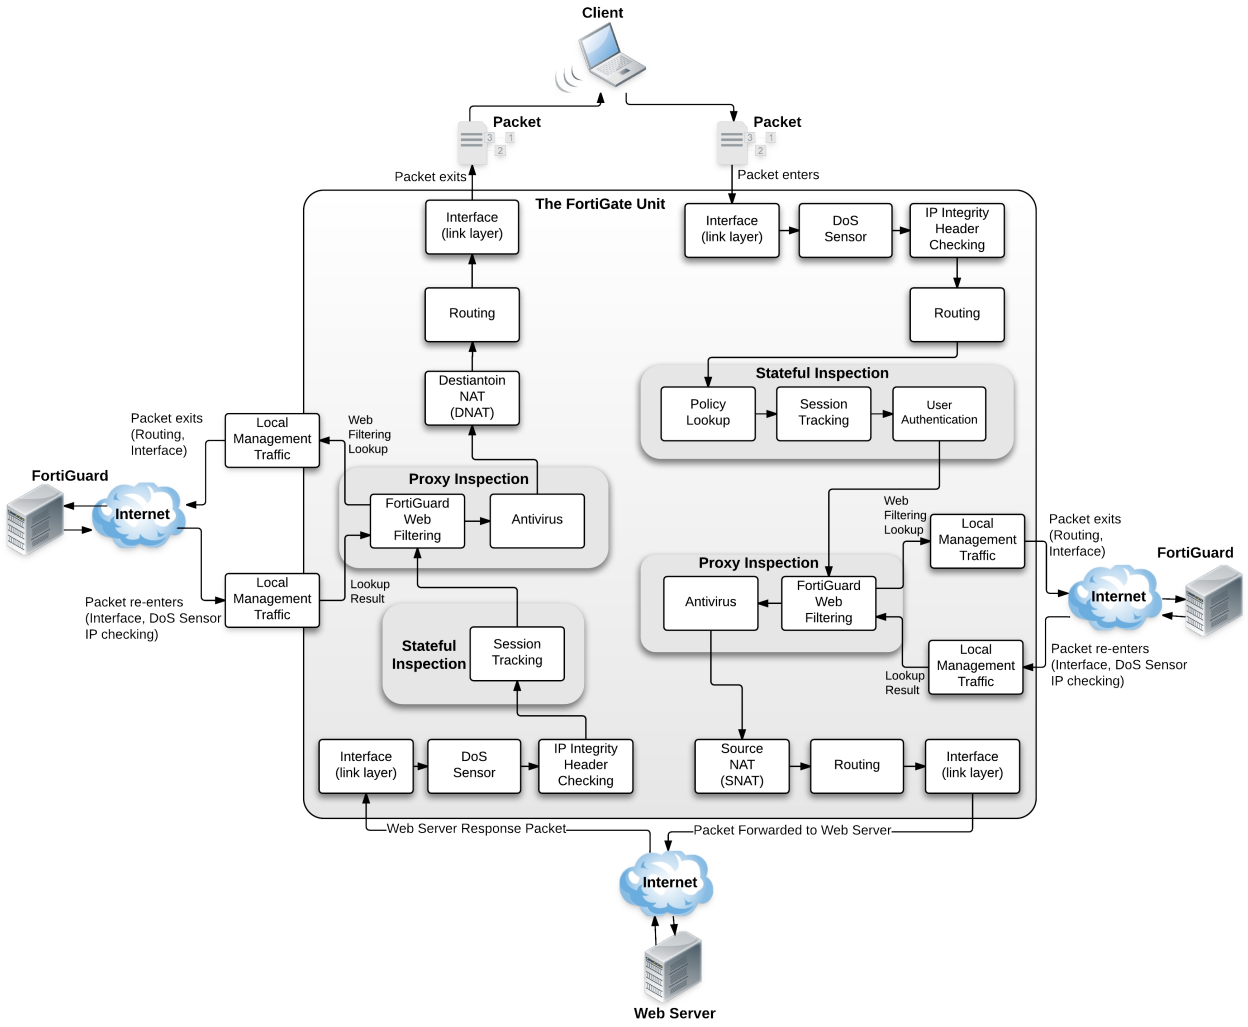
Initiating connection from client to web server

1. Client sends packet to web server.
2. The packed is routed to a FortiGate interface.
3. DoS sensor checks to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking. If the packet is OK it continues, otherwise it is dropped.
5. Routing.
6. Policy lookup.
7. User authentication.
8. Proxy-based inspection:
   - FortiGuard Web Filtering (FortiGuard web filtering lookup)
   - Antivirus
9. Source NAT changes the source address to the FortiGate IP address.
10. Routing.
11. Interface transmission to network.
12. Packet forwarded to web server.

Response from web server

1. Web Server sends response packet to client.
2. The packed is routed to a FortiGate interface.
3. DoS sensor checks to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking. If the packet is OK it continues, otherwise it is dropped.
5. Stateful inspection recognizes the packet is part and an established session.
6. Source NAT changes the destination address from the FortiGate interface back to the client IP address
7. Proxy-based inspection:
   - FortiGuard Web Filtering (FortiGuard Web Filtering lookup)
   - Antivirus
8. Packet is routed to the client.
9. Interface transmission to network
10. Packet returns to client

Life of a packet - Client/server connection



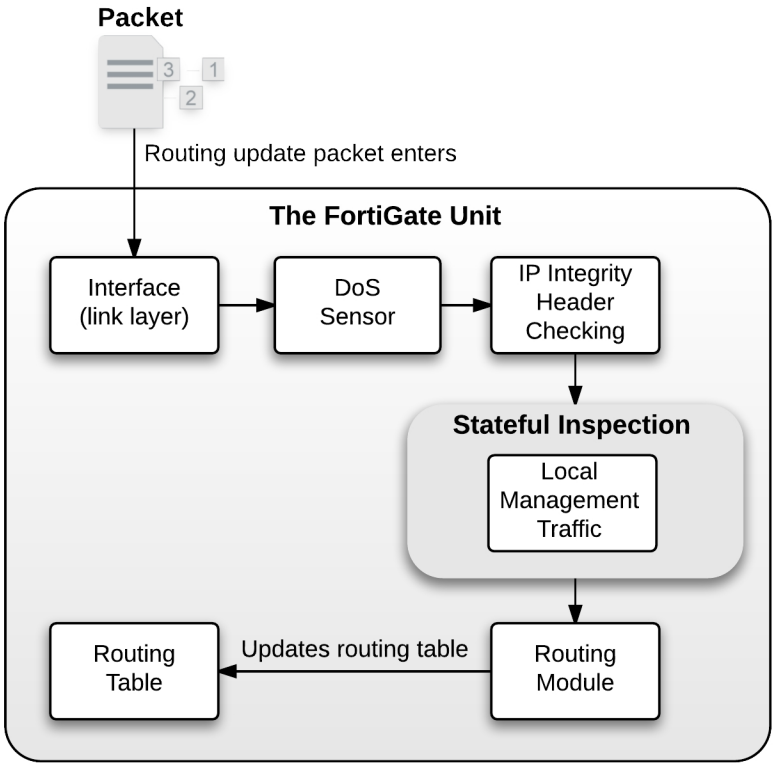
Routing table update packet flow example

The following example illustrates the flow of a packet when there is a routing table update. As this is low level, there is no security involved. This example includes the following steps:

1. FortiGate unit receives routing update packet
2. Packet intercepted by FortiGate unit interface.
3. DoS sensor checks to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking. If the packet is OK it continues, otherwise it is dropped.
5. Stateful policy engine
   Local Management traffic
6. Routing module
   Update routing table

The figure below illustrates the process steps.

Life of a Packet - Routing table update



Dialup IPsec VPN with Application control example

This example includes these steps:

1. FortiGate unit receives IPsec encrypted packet from the Internet.
2. Packet intercepted by FortiGate unit interface.
3. DoS sensor checks to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking. If the packet is OK it continues, otherwise it is dropped.
5. IPsec
   - Packet matches IPsec phase 1
   - Packet is unencrypted
6. Interface policy
7. Destination NAT
8. Next hop route
9. Stateful Inspection
   - Session Tracking
9. Flow-based inspection
   - IPS
   - Application Control
10. Source NAT
11. Routing
12. Interface transmission to network
13. Packet forwarded to internal server

Response from server

1. Server sends response packet
2. Packet intercepted by FortiGate unit interface
3. DoS sensor checks to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking. If the packet is OK it continues, otherwise it is dropped.
5. Destination NAT
6. Flow-based inspection
   - IPS
   - Application Control
7. Stateful Inspection
   - Session Tracking
8. IPsec
   - Packet is encrypted
9. Routing
10. Interface transmission to network
11. Encrypted Packet returns to internet

Chapter 17 - Load Balancing

FortiOS server load balancing includes the features you would expect of any server load balancing solution. Traffic can be distributed across multiple backend servers based on multiple methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL or generic TCP/UDP or IP protocols. Session persistence is supported based on the SSL session ID or based on an injected HTTP cookie.

Before you begin

Before you begin to configure load balancing from the web-based manager you should go to **System > Config > Features** and turn on **Load Balancing**. To find Load Balancing select the **Show More** button.

How this chapter is organized

This document contains detailed information about how to configure firewall server load balancing to load balance various types of traffic to multiple backend servers. This document describes all server load balancing configuration options and contains detailed configuration examples.

This FortiOS Handbook chapter contains the following sections:

Configuring load balancing describes FortiOS server load balancing.

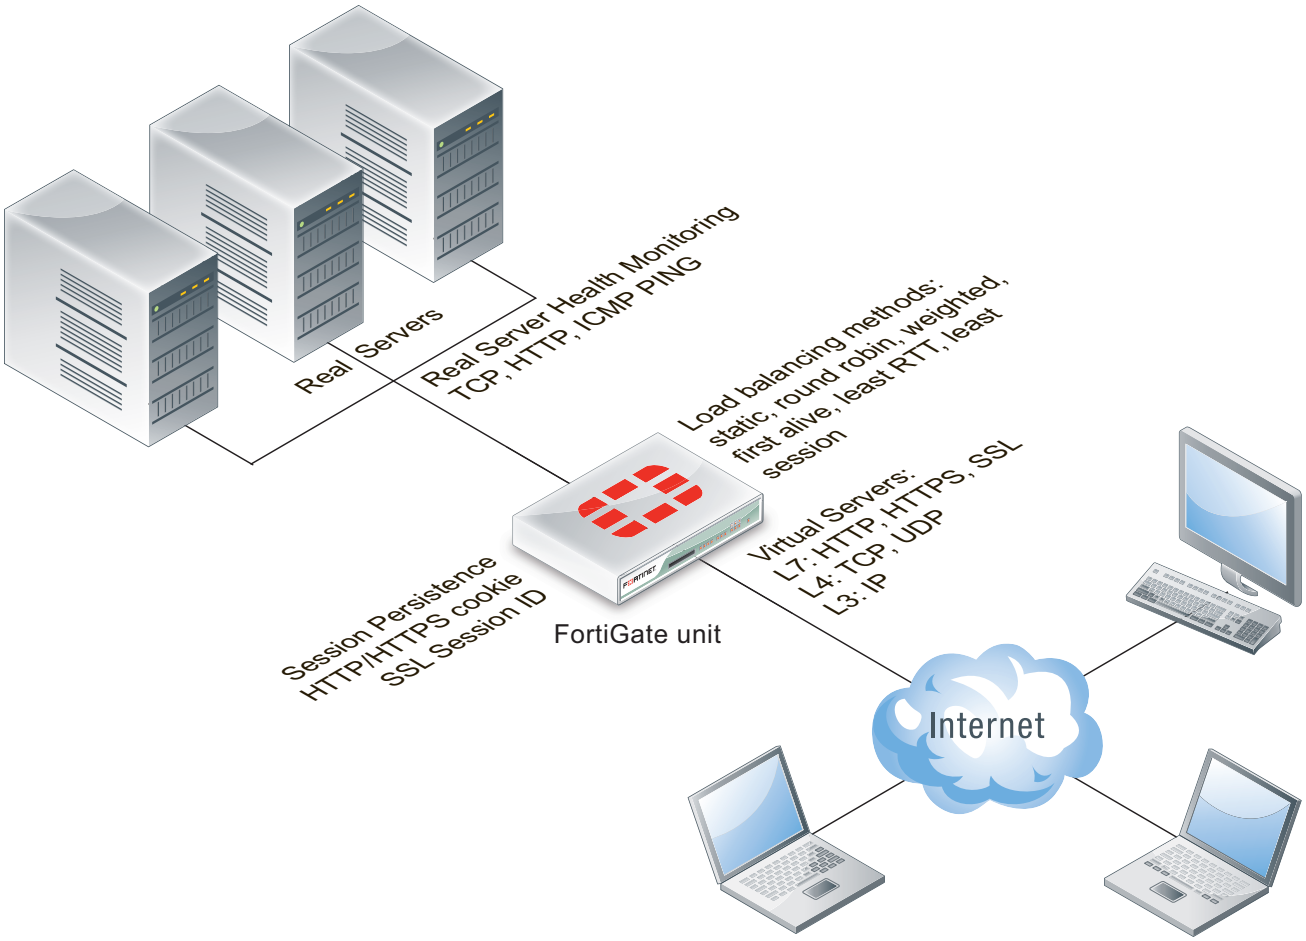
Load balancing configuration examples describes some basic and advanced load balancing configurations.

Configuring load balancing

This section describes how to use the FortiOS server load balancing to load balance traffic to multiple backend servers.

You can configure FortiOS load balancing to intercept incoming traffic with a virtual server and distribute it among one or more backend real servers. By doing so, FortiOS enables multiple real servers to respond as if they were a single device or virtual server. This in turn means that more simultaneous requests can be handled by the servers.

Server load balancing configuration



Traffic can be balanced across multiple backend real servers based on a selection of load balancing methods including static (failover), round robin, weighted to account for different sized servers, or based on the health and performance of the server including round trip time, number of connections. The load balancer can balance layer 7 HTTP, HTTPS, SSL, generic layer 4 TCP, UDP and generic layer 3 IP protocols. Session persistence is supported based on injected HTTP/HTTPS cookies or the SSL session ID.

You can bind up to 8 real servers can to one virtual server. The real server topology is transparent to end users, and the users interact with the system as if it were only a single server with the IP address and port number of the virtual server. The real servers may be interconnected by high-speed LAN or by geographically dispersed WAN.

The FortiGate unit schedules requests to the real servers and makes parallel services of the virtual server to appear to involve a single IP address.

There are additional benefits to load balancing. First, because the load is distributed across multiple servers, the service being provided can be highly available. If one of the servers breaks down, the load can still be handled by the other servers. Secondly, this increases scalability. If the load increases substantially, more servers can be added behind the FortiGate unit in order to cope with the increased load.

Load balancing and other FortiOS features

Flow-based and proxy-based security features such as virus scanning, IPS, DLP, application control, and web filtering can be applied to load balanced sessions. This includes SSL offloading and multiplexing. Applying these UTM features to load balancing traffic may reduce load balancing performance.

Authentication is not supported for load balancing sessions. Usually FortiGate load balancing is used to allow public access to services on servers protected by a FortiGate unit. Authentication is not generally not required for this kind of configuration.

Features such web proxying, web caching, and WAN optimization also do not work with load balanced sessions. However, most other features that can be applied by a security policy are supported.

Configuring load balancing from the web-based manager

A virtual server is a specialized firewall virtual IP that performs server load balancing. From the web-based manager you add load balancing virtual server by going to **Policy & Objects > Load Balance > Virtual Servers**.

Name

Enter the name for the virtual server.

Type

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as **IP**, **TCP**, or **UDP** the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as **HTTP**, **HTTPS**, or **SSL** you can apply additional server load balancing features such as **Persistence** and **HTTP Multiplexing**.

- Select **HTTP** to load balance only HTTP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can also select **HTTP Multiplex**. You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence.
- Select **HTTPS** to load balance only HTTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can also select **Multiplex HTTP requests/responses.** You can also set **Persistence** to **HTTP Cookie** to select cookie-based persistence. You can also set **Persistence** to **SSL Session ID**.
- Select **IMAPS** to load balance only IMAPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set **Persistence** to **SSL Session ID**.

- Select **POP3S** to load balance only POP3S sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SMTPS** to load balance only SMTPS sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced (usually port 465 for SMTPS sessions). You can also set **Persistence** to **SSL Session ID**.
- Select **SSL** to load balance only SSL sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **TCP** to load balance only TCP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **UDP** to load balance only UDP sessions with destination port number that matches the **Virtual Server Port** setting. Change **Virtual Server Port** to match the destination port of the sessions to be load balanced.
- Select **IP** to load balance all sessions accepted by the security policy that contains this virtual server.

Interface

Select the virtual server external interface from the list. The external interface is connected to the source network and receives the packets to be forwarded to the destination network.

Virtual Server IP

The IP address of the virtual server. This is an IP address on the external interface that you want to map to an address on the destination network.

Virtual Server Port

Enter the external port number that you want to map to a port number on the destination network. Sessions with this destination port are load balanced by this virtual server.

Load Balance Method

Select the load balancing method used by the virtual server.

Persistence

Configure persistence to make sure that a user is connected to the same server every time they make a request that is part of the same session. Session persistence is supported for HTTP and SSL sessions.

HTTP Multiplexing

Select to use the FortiGate unit to multiplex multiple client connections into a few connections between the FortiGate unit and the real server.

Preserve Client IP

Select to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

This option appears only if **HTTP** or **HTTS** are selected for **Type**, and is available only if **HTTP Multiplexing** is selected.

SSL Offloading

Select to accelerate clients' SSL connections to the server by using the Fortinet FortiGate unit to perform SSL operations, then select which segments of the connection will receive SSL offloading.

Certificate

Select the certificate to use with **SSL Offloading**. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

This option appears only if **HTTPS** or **SSL** are selected for **Type**, and is available only if **SSL Offloading** is selected.

Health Check

Select which health check monitor configuration will be used to determine a server's connectivity status.

Configuring load balancing from the CLI

From the CLI you configure load balancing by adding a firewall virtual IP and setting the virtual IP type to server load balance:

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      ...
```

A virtual server includes a virtual server IP address bound to an interface. The virtual server IP address is the destination address incoming packets to be load balanced and the virtual server is bound to the interface that receives the packets to be load balanced.

For example, if you want to load balance incoming HTTP traffic from the Internet to a group of web servers on a DMZ network, the virtual server IP address is the known Internet IP address of the web servers and the virtual server binds this IP address to the FortiGate interface connected to the Internet.

When you bind the virtual server's external IP address to a FortiGate unit interface, by default, the network interface responds to ARP requests for the bound IP address. Virtual servers use proxy ARP, as defined in RFC 1027, so that the FortiGate unit can respond to ARP requests on a network for a real server that is actually installed on another network. In some cases you may not want the network interface sending ARP replies. You can use the `arp-reply` option disable sending ARP replies:

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      set arp-reply disable
      ...
```

The load balancing virtual server configuration also includes the virtual server port. This is the TCP port on the bound interface that the virtual server listens for traffic to be load balanced on. The virtual server can listen on any port.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers. A number of load balancing methods are available as listed below.

All load balancing methods will not send traffic to real servers that are down or not responding. However, the FortiGate unit can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to individual real servers, or load balancing methods may attempt to distribute sessions to real servers that are not functioning.

Source IP Hash

The traffic load is statically spread evenly across all real servers. However, sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. However, the distribution is stateless, so if a real server is added or removed (or goes up or down) the distribution is changed and persistence could be lost.

Round Robin

Directs new requests to the next real server, and treats all real servers as equals regardless of response time or number of connections. Dead real servers or non responsive real servers are avoided.

Weighted

Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.

First Alive

Always directs sessions to the first alive real server. This load balancing schedule provides real server failover protection by sending all sessions to the first alive real server and if that real server fails, sending all sessions to the next alive real server. Sessions are not distributed to all real servers so all sessions are processed by the “first” real server only.

First refers to the order of the real servers in the virtual server configuration. For example, if you add real servers A, B and C in that order, then all sessions always go to A as long as it is alive. If A goes down then sessions go to B and if B goes down sessions go to C. If A comes back up sessions go back to A. Real servers are ordered in the virtual server configuration in the order in which you add them, with the most recently added real server last. If you want to change the order you must delete and re-add real servers in the required order.

Least RTT

Directs sessions to the real server with the least round trip time. The round trip time is determined by a Ping health check monitor and is defaulted to 0 if no Ping health check monitors are added to the virtual server.

Least Session

Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.

HTTP Host

Load balances HTTP host connections across multiple real servers using the host’s HTTP header to guide the connection to the correct real server.

Session persistence

Use persistence to make sure that a user is connected to the same real server every time they make an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when a user is making a purchase they will be starting multiple sessions as they navigate the eCommerce site. In most cases all of the sessions started by this user during on eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence makes sure that all sessions that are part of the same user session are processed by the same real server

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server. For more information about HTTP and HTTPS persistence, see "HTTP and HTTPS persistence".

Real servers

Add real servers to a load balancing virtual server to provide the information the virtual server requires to be able to send sessions to the server. A real server configuration includes the IP address of the real server and port number that the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server you can also specify the weight (used if the load balance method is set to weighted) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests other real servers until the connection number drops below the specified limit. Setting Maximum Connections to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Real server active, standby, and disabled modes

By default the real server mode setting is active indicating that the real server is available to receive connections. If the real server is removed from the network (for example, for routine maintenance or because of a hardware or software failure) you can change the mode to standby or disabled. In disabled mode the FortiGate unit no longer sends sessions to the real server.

If a real server is in standby mode the FortiGate also does not send sessions to it unless other real servers added to the same virtual server become unavailable. For example:

- A virtual server that includes two real servers one in active mode and one in standby mode. If the real server in active mode fails, the real server in standby mode is changed to active mode and all sessions are sent to this real server.
- A virtual server includes three real servers, two in active mode and one in standby mode, if one of the real servers in active mode fails, the real server in standby mode is changed to active mode and sessions are load balanced between it and still operating real server. If both real servers in active mode fail, all sessions are sent to the real server in standby mode.

Adding real servers from the web-based manager

To add a real server from the web-based manager go to **Policy & Objects > Load Balance > Real Servers**.

Virtual Server

Select the virtual server that will send sessions to this real server.

IP Address

Enter the IP address of the real server.

Port

Enter the port number on the destination network to which the external port number is mapped.

Weight

Enter the weight value of the real server. The higher the weight value, the higher the percentage of connections the server will handle. A range of 1-255 can be used. This option is available only if the associated virtual server's load balance method is **Weighted**.

Max Connections

Enter the limit on the number of active connections directed to a real server. A range of 1-99999 can be used. If the maximum number of connections is reached for the real server, the FortiGate unit will automatically switch all further connection requests to another server until the connection number drops below the specified limit.

Setting **Maximum Connections** to **0** means that the FortiGate unit does not limit the number of connections to the real server.

HTTP Host

Enter the HTTP header for load balancing across multiple real servers. This feature is used for load balancing HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server, providing better load balancing for those specific connections.

Mode

Select a mode for the real server.

Adding real servers from the CLI

To add a real server from the CLI you configure a virtual server and add real servers to it. For example, to add three real servers to a virtual server that load balances UDP sessions on port 8190 using weighted load balancing. For each real server the port is not changed. The default real server port is 0 resulting in the traffic being sent the real server with destination port 8190. Each real sever is given a different weight. Servers with higher weights have a max-connections limit to prevent too many sessions from being sent to them.

```
config firewall vip
   edit Vserver-UDP-1
      set type server-load-balance
      set server-type udp
      set ldb-method weighted
      set extip 172.20.120.30
      set extintf wan1
      set extport 8190
```

```
    set monitor ping-mon-1
       config realservers
          edit 1
             set ip 10.31.101.30
             set weight 100
             set max-connections 10000
          next
          edit 2
             set ip 10.31.101.40
             set weight 100
             set max-connections 10000
          next
          edit 3
             set ip 10.31.101.50
             set weight 10
          end
end
```

Health check monitoring

From the FortiGate web-based manager you can go to **Policy & Objects > Load Balance > Health Check** and configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts the load balancer continues to send sessions to it. If a real server stops responding to connection attempts the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the load balancer tests the real servers. You can use a single health check monitor for multiple load balancing configurations.

You can configure TCP, HTTP and Ping health check monitors. Usually you would want the health check monitor to use the same protocol for checking the health of the server as the traffic being load balanced to it. For example, for an HTTP load balancing configuration you would normally use an HTTP health check monitor.

For the TCP and HTTP health check monitors you can specify the destination port to use to connect to the real servers. If you set the port to 0, the health check monitor uses the port defined in the real server. This allows you to use the same health check monitor for multiple real servers using different ports. You can also configure the interval, timeout and retry. A health check occurs every number of seconds indicated by the interval. If a reply is not received within the timeout period the health check is repeated every second. If no response is received after the number of configured retires, the virtual server is considered unresponsive, and load balancing will disabling traffic to that real server. The health check monitor will continue to contact the real server and if successful, the load balancer can resume sending sessions to the recovered real server.

The default health check configuration has an interval of 10 seconds, a timeout of 2 seconds and a retry of 3. This means that the health check monitor checks the health of a real server every 10 seconds. If a reply is not received within 2 seconds the health check monitor re-checks the server every second for 3 retries. If no response is received for 2 seconds after the final retry the server is considered unresponsive. This entire process takes a total of 7 seconds to consider a virtual server as unresponsive (2 second timeout + (3 re-checks x 1 second) + 2 second timeout = 7 seconds). Since this health check process is repeated every 10 seconds, a server can be down for a maximum of 10 + 7 = 17 seconds before the health check monitor considers it down.

For HTTP health check monitors, you can add URL that the FortiGate unit connects to when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.31.101.30, the URL "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.31.101.30/test_page.htm".

For HTTP health check monitors, you can also add a matched content phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the URL option. If the URL returns a web page, the matched content should exactly match some of the text on the web page. You can use the URL and Matched Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set matched content to "server test page" if the real HTTP server page defined by the URL option contains the phrase "server test page". When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the matched content phrase.

Name

Enter the name of the health check monitor configuration.

Type

Select the protocol used to perform the health check.

- TCP
- HTTP
- PING

Port

Enter the port number used to perform the health check. If you set the **Port** to 0, the health check monitor uses the port defined in the real server. This way you can use a single health check monitor for different real servers.

This option does not appear if the **Type** is **PING**.

Interval

Enter the number of seconds between each server health check.

URL

For HTTP health check monitors, add a URL that the FortiGate unit uses when sending a get request to check the health of a HTTP server. The URL should match an actual URL for the real HTTP servers. The URL is optional.

The URL would not usually include an IP address or domain name. Instead it should start with a "/" and be followed by the address of an actual web page on the real server. For example, if the IP address of the real server is 10.10.10.1, the **URL** "/test_page.htm" causes the FortiGate unit to send an HTTP get request to "http://10.10.10.1/test_page.htm".

This option appears only if **Type** is **HTTP**.

Matched Content

For HTTP health check monitors, add a phrase that a real HTTP server should include in response to the get request sent by the FortiGate unit using the content of the **URL** option. If the **URL** returns a web page, the **Matched Content** should exactly match some of the text on the web page. You can use the **URL** and **Matched**

Content options to verify that an HTTP server is actually operating correctly by responding to get requests with expected web pages. Matched content is only required if you add a URL.

For example, you can set **Matched Content** to “server test page” if the real HTTP server page defined by the URL option contains the phrase “server test page”. When the FortiGate unit receives the web page in response to the URL get request, the system searches the content of the web page for the **Matched Content** phrase.

This option appears only if **Type** is **HTTP**.

Timeout

Enter the number of seconds which must pass after the server health check to indicate a failed health check.

Retry

Enter the number of times, if any, a failed health check will be retried before the server is determined to be inaccessible.

Load balancing limitations

The following limitations apply when adding virtual IPs, load balancing virtual servers, and load balancing real servers. Load balancing virtual servers are actually server load balancing virtual IPs. You can add server load balance virtual IPs from the CLI.

- Virtual IP **External IP Address/Range** entries or ranges cannot overlap with each other or with load balancing virtual server **Virtual Server IP** entries.
- A virtual IP **Mapped IP Address/Range** cannot be 0.0.0.0 or 255.255.255.255.
- A real server **IP** cannot be 0.0.0.0 or 255.255.255.255.
- If a static NAT virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** must be a single IP address.
- If a load balance virtual IP **External IP Address/Range** is 0.0.0.0, the **Mapped IP Address/Range** can be an address range.
- When port forwarding, the count of mapped port numbers and external port numbers must be the same. The web-based manager does this automatically but the CLI does not.
- Virtual IP and virtual server names must be different from firewall address or address group names.

Monitoring load balancing

From the web-based manager you can go to **Policy & Objects > Monitor > Load Balance Monitor** to monitor the status of configured virtual servers and real server and start or stop the real servers. You can also use the `get test ipldb` command from the CLI to display similar information.

For each real server the monitor displays health status (up or down), active sessions, round trip time and the amount of bytes of data processed. From the monitor page you can also stop sending new sessions to any real server. When you select to stop sending sessions the FortiGate unit performs of graceful stop by continuing to send data for sessions that were established or persistent before you selected stop. However, no new sessions are started.

Virtual Server

The IP addresses of the existing virtual servers.

Real Server

The IP addresses of the existing real servers.

Health Status

Displays the health status according to the health check results for each real server. A green arrow means the server is up. A red arrow means the server is down.

Mode

The mode of the health check monitor. Can be active, standby, or disabled.

Monitor Events

Display each real server's up and down times.

Active Sessions

Display each real server's active sessions.

RTT (ms)

Displays the Round Trip TIme (RTT) of each real server. By default, the RTT is "<1". This value will change only when ping monitoring is enabled on a real server.

Bytes Processed

Displays the traffic processed by each real server.

Graceful Stop/Start

Select to start or stop real servers. When stopping a server, the FortiGate unit will not accept new sessions but will wait for the active sessions to finish.

Load balancing diagnose commands

You can also use the following diagnose commands to view status information for load balancing virtual servers and real servers:

```
diagnose firewall vip realserver {down | flush | healthcheck | list | up}
diagnose firewall vip virtual-server {filter | log | real-server | session | stats}
```

For example, the following command lists and displays status information for all real servers:

```
diagnose firewall vip virtual-server real-server

vd root/0 vs vs/2 addr 10.31.101.30:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0

vd root/0 vs vs/2 addr 10.31.101.20:80 status 1/1
conn: max 0 active 0 attempts 0 success 0 drop 0 fail 0
```

Many of the diagnostic commands involve retrieving information about one or more virtual servers. To control which servers are queried you can define a filter:

```
diagnose firewall vip virtual-server filter <filter_str>
```

Where <filter_str> can be:

- clear erase the current filter
- dst the destination address range to filter by
- dst-port the destination port range to filter by
- list display the current filter
- name the vip name to filter by
- negate negate the specified filter parameter
- src the source address range to filter by
- src-port the source port range to filter by
- vd index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Logging Diagnostics

The logging diagnostics provide information about two separate features:

```
diagnose firewall vip virtual-server log {console | filter}
```

Where

- console {disable | enable} enables or disables displaying the event log messages generated by virtual server traffic on the console to simplify debugging.
- filter sets a filter for the virtual server debug log
- The filter option controls what entries the virtual server daemon will log to the console if diagnose debug application vs level is non-zero. The filtering can be done on source, destination, virtual-server name, virtual domain, and so on:

```
diagnose firewall vip virtual-server log filter <filter_str>
```

Where <filter_str> can be

- clear erase the current filter
- dst the destination address range to filter by
- dst-port the destination port range to filter by
- list display the current filter
- name the virtual-server name to filter by
- negate negate the specified filter parameter
- src the source address range to filter by
- src-port the source port range to filter by
- vd index of virtual domain. -1 matches all

The default filter is empty so no filtering is done.

Real server diagnostics

Enter the following command to list all the real servers:

```
diag firewall vip virtual-server real-server list
```

In the following example there is only one virtual server called slb and it has two real-servers:

```
diag firewall vip virtual-server server
vd root/0 vs slb/2 addr 172.16.67.191:80 status 1/1
conn: max 10 active 0 attempts 0 success 0 drop 0 fail 0
http: available 0 total 0
```

```
vd root/0 vs slb/2 addr 172.16.67.192:80 status 1/1
conn: max 10 active 1 attempts 4 success 4 drop 0 fail 0
http: available 1 total 1
```

The `status` indicates the administrative and operational status of the real-server.

- `max` indicates that the real-server will only allow 10 concurrent connections.
- `active` is the number of current connections to the server attempts is the total number of connections attempted success is the total number of connections that were successful.
- `drop` is the total number of connections that were dropped because the active count hit max.
- `fail` is the total number of connections that failed to complete due to some internal problem (for example, lack of memory).

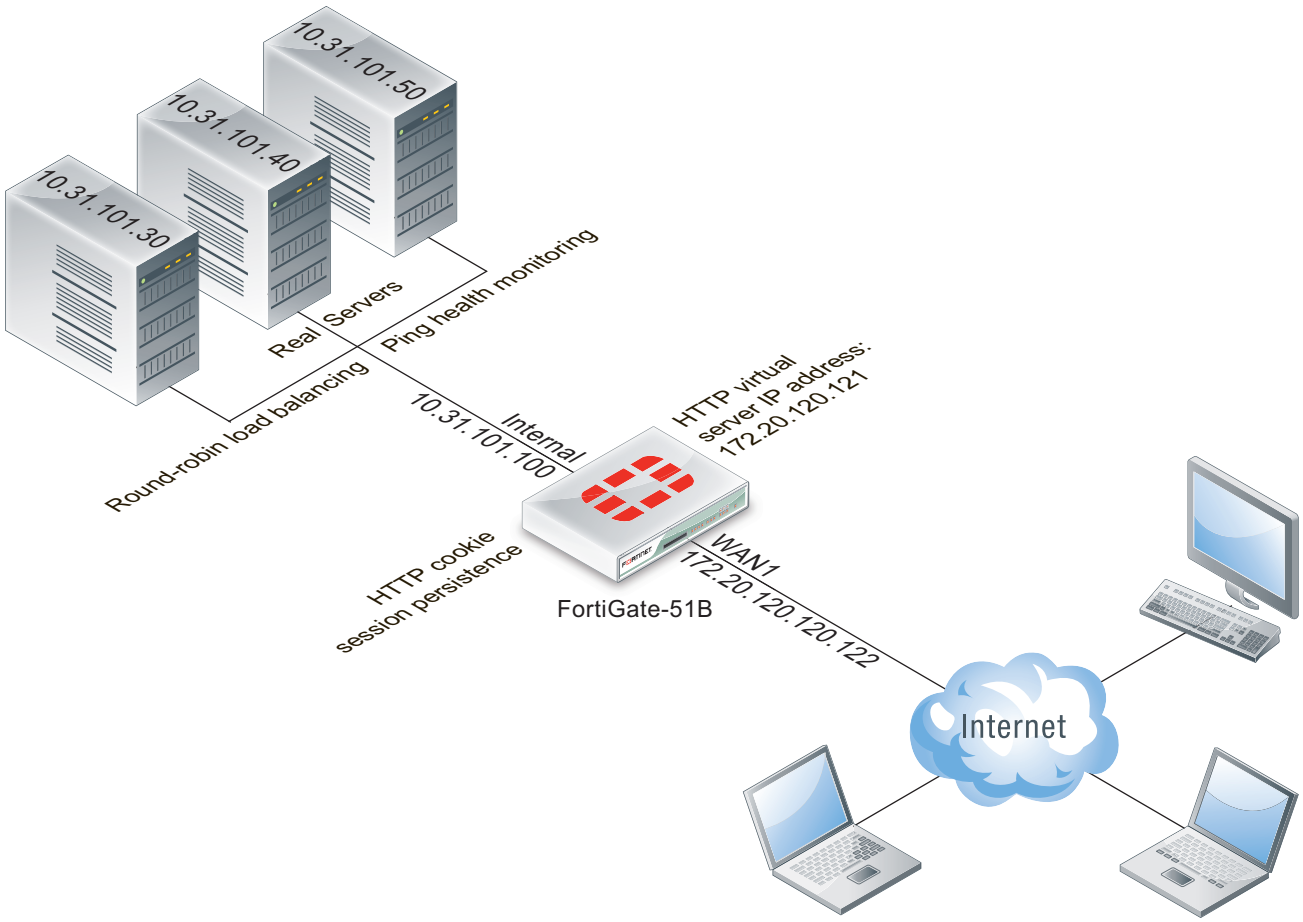
If the virtual server has HTTP multiplexing enabled then the HTTP section indicates how many established connections to the real-sever are available to service a HTTP request and also the total number of connections.

Basic load balancing configuration example

This section describes the steps required to configure the load balancing configuration shown below. In this configuration a FortiGate-51B unit is load balancing HTTP traffic from the Internet to three HTTP servers on the Internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080 and forwarded from the internal interface to the web servers. When forwarded the destination address of the sessions is translated to the IP address of one of the web servers.

The load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to make sure the web servers can respond to network traffic.

Virtual server and real servers setup



To configure the example load balancing configuration - general configuration steps

1. Add a load balance ping health check monitor.
   A ping health check monitor causes the FortiGate unit to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Add a load balance virtual server.
3. Add the three load balance real servers. Include the virtual server in each real server configuration.
4. Add a security policy that includes the load balance virtual server as the destination address.

To configure the example load balancing configuration - web-based manager

1. Go to **Policy & Objects > Load Balance > Health Check** and add the following health check monitor.

Name	Ping-mon-1
Type	Ping

Interval	10 seconds
Timeout	2 seconds
Retry	3

2. Go to **Policy & Objects > Load Balance > Virtual Servers** and add virtual server that accepts the traffic to be load balanced.

Name	Vserver-HTTP-1
Type	HTTP
Interface	wan1
Virtual Server IP	172.20.120.121
Virtual Server Port	8080
Load Balance Method	Round Robin
Persistence	HTTP Cookie
HTTP Multiplexing	Do not select
Health Check	Move Ping-mon-1 to the Selected list.

3. Go to **Policy & Objects > Load Balance > Real Servers** and add the real servers.

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.30
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.40
Port	80
Weight	n/a
Max Connections	0
Mode	Active

Virtual Server	Vserver-HTTP-1
IP Address	10.31.101.50
Port	80
Weight	n/a
Max Connections	0
Mode	Active

4. Go to **Policy & Objects > Policy > IPv4** and add a wan1 to internal security policy that includes the virtual server. This policy also applies an Antivirus profile to the load balanced sessions.

Incoming Interface	wan1
Source Address	all
Outgoing Interface	internal
Destination Address	Vserver-HTTP-1
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Turn on NAT and select **Use Destination Interface Address**.
Antivirus	Turn ON and select an Antivirus profile.

5. Select **OK**.

To configure the example load balancing configuration- CLI

1. Use the following command to add a Ping health check monitor.

```
config firewall ldb-monitor
   edit ping-mon-1
      set type ping
      set interval 10
      set timeout 2
      set retry 3
   end
```

2. Use the following command to add the virtual server that accepts HTTP sessions on port 8080 at the wan1 interface and load balances the traffic to three real servers.

```
config firewall vip
   edit Vserver-HTTP-1
      set type server-load-balance
      set server-type http
      set ldb-method round-robin
      set extip 172.20.120.30
      set extintf wan1
      set extport 8080
      set persistence http-cookie
```

```
      set monitor tcp-mon-1
         config realservers
            edit 1
               set ip 10.31.101.30
               set port 80
            next
            edit 2
               set ip 10.31.101.40
               set port 80
            end
end
```

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
   edit 0
      set srcintf wan1
      set srcaddr all
      set dstintf internal
      set dstaddr Vserver-HTTP-1
      set action accept
      set schedule always
      set service ALL
      set nat enable
      set utm-status enable
      set profile-protocol-options default
      set av-profile scan
   end
```

HTTP and HTTPS load balancing, multiplexing, and persistence

In a firewall load balancing virtual server configuration, you can select HTTP to load balance only HTTP sessions. The virtual server will load balance HTTP sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches the configured virtual server port. The default virtual server port for HTTP load balancing is 80, but you can change this to any port number. Similarly for HTTPS load balancing, set the virtual server type to HTTPS and then select the interface, virtual server IP, and virtual server port that matches the HTTPS traffic to be load balanced. Usually HTTPS traffic uses port 443.

You can also configure load balancing to offload SSL processing for HTTPS and SSL traffic. See "SSL offloading" for more information.

HTTP and HTTPS multiplexing

For both HTTP and HTTPS load balancing you can multiplex HTTP requests and responses over a single TCP connection. HTTP multiplexing is a performance saving feature of HTTP/1.1 compliant web servers that provides the ability to pipeline many unrelated HTTP or HTTPS requests on the same connection. This allows a single HTTPD process on the server to interleave and serve multiple requests. The result is fewer idle sessions on the web server so server resources are used more efficiently. HTTP multiplexing can take multiple separate inbound sessions and multiplex them over the same internal session. This may reduce the load on the backend server and increase the overall performance.

HTTP multiplexing may improve performance in some cases. For example, if users web browsers are only compatible with HTTP 1.0. HTTP multiplexing can also improve performance between a web server and the

FortiGate unit if the FortiGate unit is performing SSL acceleration. However, in most cases HTTP multiplexing should only be used if enabling it leads to a measurable improvement in performance.

To enable HTTP multiplexing from the web-based manager, select multiplex HTTP requests/responses over a single TCP connection. To enable HTTP multiplexing from the CLI enable the `http-multiplex` option.

Preserving the client IP address

Select preserve client IP from the web-based manager or enable the `http-ip-header` option from the CLI to preserve the IP address of the client in the `X-Forwarded-For` HTTP header. This can be useful in an HTTP multiplexing configuration if you want log messages on the real servers to the client's original IP address. If this option is not selected, the header will contain the IP address of the FortiGate unit.

Preserving the client IP address but changing the X-Forwarded-For header name

If you select preserve client IP from the web-based manager or enable the `http-ip-header` option from the CLI you can also change the name of the `X-Forwarded-For` header to a custom header name. This can be useful if you want to use a custom header name instead of the standard header name.

You can configure changing the header name from the CLI. When `http-ip-header` is enabled you can add a custom header name to the `http-ip-header-name` option. If you don't add a custom header name the `X-Forwarded-For` header name is maintained.

HTTP and HTTPS persistence

Configure load balancing persistence for HTTP or HTTPS to make sure that a user is connected to the same server every time they make a request that is part of the same session. HTTP cookie persistence uses injected cookies to enable persistence.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

The following example shows how to enable cookie persistence and set the cookie domain to .example.org.

```
config firewall vip
   edit HTTP_Load_Balance
      set type server-load-balance
      set server-type http
      set extport 8080
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
      set http-cookie-domain .example.org
         config realservers
         edit 1
               set ip 10.10.10.1
               set port 80
         next
         edit 2
               set ip 10.10.10.2
               set port 80
         next
         edit 3
               set ip 10.10.10.3
               set port 80
```

```
    end
```

How HTTP cookie persistence options work

The following options are available for the `config firewall vip` command when `type` is set to `server-load-balance`, `server-type` is set to `http` or `https` and `persistence` is set to `http-cookie`:

```
http-cookie-domain-from-host
http-cookie-domain
http-cookie-path
http-cookie-generation
http-cookie-age
http-cookie-share
https-cookie-share
```

When HTTP cookie persistence is enabled the FortiGate unit inserts a header of the following form into each HTTP response unless the corresponding HTTP request already contains a `FGTServer` cookie:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600
```

The value of the `FGTServer` cookie encodes the server that traffic should be directed to. The value is encoded so as to not leak information about the internal network.

Enable `http-cookie-domain-from-host` to extract the cookie domain from the `host:` header in the HTTP request. For example, to restrict the cookie to `.server.com`, enter:

The generated cookies could have the following form if the **Host:** header contains **exhost.com**:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.exhost.com; Max-Age=3600
```

For more information, see "HTTP host-based load balancing".

Use `http-cookie-domain` to restrict the domain that the cookie should apply to. For example, to restrict the cookie to `.server.com`, enter:

```
set http-cookie-domain .server.com
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Max-Age=3600
```

Use `http-cookie-path` to limit the cookies to a particular path. For example, to limit cookies to the path `/sales`, enter:

```
set http-cookie-path /sales
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Path=/sales; Max-Age=3600
```

Use `http-cookie-age` to change how long the browser caches the cookie. You can enter an age in minutes or set the age to 0 to make the browser keep the cookie indefinitely:

```
set http-cookie-age 0
```

Now all generated cookies will have the following form:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1;
    Domain=.server.com; Path=/sales
```

Use `http-cookie-generation` to invalidate all cookies that have already been generated. The exact value of the generation is not important, only that it is different from any generation that has already been used for cookies in this domain. The simplest approach is to increment the generation by one each time invalidation is required. Since the default is 0, enter the following to invalidate all existing cookies:

```
set http-cookie-generation 1
```

Use `http-cookie-share {disable | same-ip}` to control the sharing of cookies across virtual servers in the same virtual domain. The default setting `same-ip` means that any `FGTServer` cookie generated by one virtual server can be used by another virtual server in the same virtual domain. For example, if you have an application that starts on HTTP and then changes to HTTPS and you want to make sure that the same server is used for the HTTP and HTTPS traffic then you can create two virtual servers, one for port 80 (for HTTP) and one for port 443 (for HTTPS). As long as you add the same real servers to both of these virtual servers (and as long as both virtual servers have the same number of real servers with the same IP addresses), then cookies generated by accessing the HTTP server are reused when the application changes to the HTTPS server.

If for any reason you do not want this sharing to occur then select `disable` to make sure that a cookie generated for a virtual server cannot be used by other virtual servers.

Use `https-cookie-secure` to enable or disable using secure cookies. Secure cookies are disabled by default because secure cookies can interfere with cookie sharing across HTTP and HTTPS virtual servers. If enabled, then the `Secure` tag is added to the cookie inserted by the FortiGate unit:

```
Set-Cookie: FGTServer=E7D01637C4B08E89A6714213A9D85D9C7E4D8158; Version=1; Max-Age=3600;
    Secure
```

HTTP host-based load balancing

When configuring HTTP or HTTPS load balancing you can select HTTP host load balancing to load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server. HTTP 1.1 includes the concept of a virtual server which allows a HTTP or HTTPS server with a single external IP address to serve requests for multiple DNS domains by using the mandatory `Host:` header in a HTTP request to indicate which DNS domain the request is destined for.

FortiOS can load-balance HTTP and HTTPS connections among multiple real servers using the `Host:` header to guide the connection to the correct real server. The host load balancing method allows a real server to specify a `http-host` attribute which is the domain name of the traffic for that real server. Each real server can only specify a single domain name. The same domain name can appear in more than one real server but only the first one that is up will be used, any others are purely for redundancy. If the Host: header contains a domain that does not match any http-host entry then the connection will be dropped. A real server with no http-host can be matched by any Host: domain.

For example, consider a FortiGate unit that is load-balancing traffic to three real servers. Traffic for www.example1.com should go to 192.168.2.1, traffic for www.example2.com should go to 192.168.2.2 and traffic to any other domain should go to 192.168.2.3. To enable this configuration you would add a virtual server and set the load balance method to HTTP host. Then you would add three real servers and set the HTTP host of the real server with IP address 192.168.2.1 to www.example1.com, the HTTP host of the real server with IP address 192.168.2.2 to www.example2.com and you would not specify an HTTP host for the third real server.

The configuration of a virtual IP to achieve this result would be:

```
config firewall vip
   edit "http-host-ldb"
      set type server-load-balance
      set extip 172.16.67.195
      set extintf "lan"
      set server-type http
      set ldb-method http-host
      set extport 80
         config realservers
         edit 1
               set http-host "www.example1.com"
```

```
            set ip 192.168.2.1
            set port 80
        next
        edit 2
            set http-host "www.example2.com"
            set ip 192.168.2.2
            set port 80
        next
        edit 3
            set ip 192.168.2.3
            set port 80
        next
        end
end
```

Host load balancing and HTTP cookie persistence

In an HTTP host-based load balancing configuration with HTTP cookie persistence enabled you can optionally configure cookie persistence to use the domain set in the host header as the cookie domain. You can do this by enabling the `http-cookie-domain-from-host` option, for example:

```
config firewall vip
   edit "http-host-ldb"
      set type server-load-balance
      set extip 172.16.67.195
      set extintf "lan"
      set server-type http
      set ldb-method http-host
      set extport 80
      set persistence http-cookie
      set http-cookie-domain-from-host enable
         config realservers
            edit 1
               set http-host "www.example1.com"
               set ip 192.168.2.1
               set port 80
            next
            edit 2
               set http-host "www.example2.com"
               set ip 192.168.2.2
               set port 80
            next
            edit 3
               set ip 192.168.2.3
               set port 80
            next
            end
end
```

SSL/TLS load balancing

In a firewall load balancing virtual server configuration, you can select SSL to load balance only SSL and TLS sessions. The virtual server will load balance SSL and TLS sessions received at the virtual server interface with destination IP address that matches the configured virtual server IP and destination port number that matches

the configured virtual server port. Change this port to match the destination port of the sessions to be load balanced.

For SSL load balancing you can also set persistence to SSL session ID. Persistence is achieved by the FortiGate unit sending all sessions with the same SSL session ID to the same real server. When you configure persistence, the FortiGate unit load balances a new session to a real server according to the **Load Balance Method**. If the session has an SSL session ID, the FortiGate unit sends all subsequent sessions with the same SSL session ID to the same real server.

SSL offloading

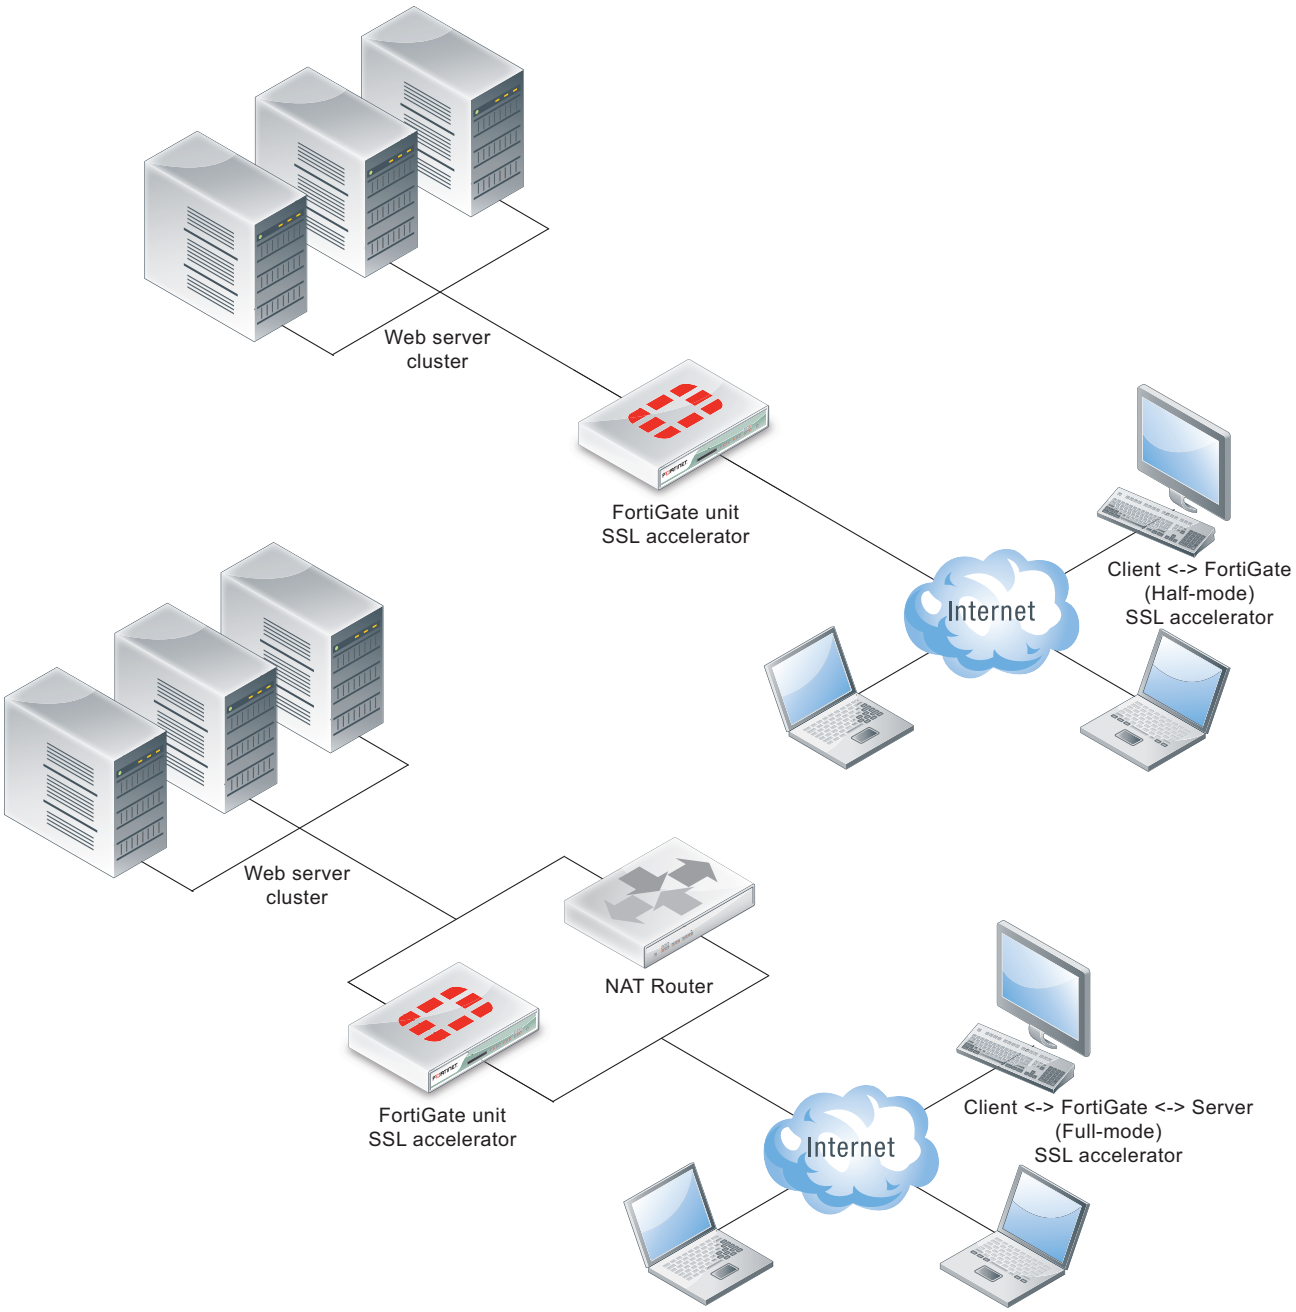
Use SSL offloading to accelerate clients' SSL or HTTPS connections to real servers by using the FortiGate unit to perform SSL operations (offloading them from the real servers using the FortiGate unit's SSL acceleration hardware). FortiGate units can offload SSL 3.0 and TLS 1.0. SSL offloading is available on FortiGate units that support SSL acceleration.

To configure SSL offloading from the web-based manager go to **Policy & Objects > Load Balance > Virtual Servers**. Add a virtual server and set the type to HTTPS or SSL and select the SSL offloading type (Client <-> FortiGate or Client <-> FortiGate <->Server).

Select Client <-> FortiGate to apply hardware accelerated SSL processing only to the part of the connection between the client and the FortiGate unit. This mode is called half mode SSL offloading. The segment between the FortiGate unit and the server will use clear text communications. This results in best performance, but cannot be used in failover configurations where the failover path does not have an SSL accelerator.

Select Client <-> FortiGate <->Server to apply hardware accelerated SSL processing to both parts of the connection: the segment between client and the FortiGate unit, and the segment between the FortiGate unit and the server. This mode is called full mode SSL offloading. The segment between the FortiGate unit and the server will use encrypted communications, but the handshakes will be abbreviated. This results in performance which is less than the other option, but still improved over communications without SSL acceleration, and can be used in failover configurations where the failover path does not have an SSL accelerator. If the server is already configured to use SSL, this also enables SSL acceleration without requiring changes to the server's configuration.

SSL Offloading modes



Configuring SSL offloading also requires selecting a certificate to use for the SSL offloading sessions. The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

The following CLI command shows an example half mode HTTPS SSL offloading configuration. In the example the `ssl-mode` option sets the SSL offload mode to `half` (which is the default mode).

```
config firewall vip
   edit Vserver-ssl-offload
      set type server-load-balance
      set server-type https
```

```
        set ldb-method round-robin
        set extip 172.20.120.30
        set extintf wan1
        set extport 443
        set persistence ssl-session-id
        set ssl-mode half
        set ssl-certificate my-cert
        set monitor t cp-mon-1
           config realservers
              edit 1
                 set ip 10.31.101.30
                 set port 443
              next
              edit 2
                 set ip 10.31.101.40
                 set port 443
              end
     end
```

Additional SSL load balancing and SSL offloading options

The following SSL load balancing and SSL offloading options are only available from the CLI:

`ssl-client-session-state-max <sessionstates_int>`

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the client and the FortiGate unit.

`ssl-client-session-state-timeout <timeout_int>`

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the client and the FortiGate unit.

`ssl-client-session-state-type {both | client | disable | time}`

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the client and the FortiGate unit.

- `both`: Select to expire SSL session states when either `ssl-client-session-state-max` or `ssl-client-session-state-timeout` is exceeded, regardless of which occurs first.
- `count`: Select to expire SSL session states when `ssl-client-session-state-max` is exceeded.
- `disable`: Select to keep no SSL session states.
- `time`: Select to expire SSL session states when `ssl-client-session-state-timeout` is exceeded.

`ssl-dh-bits <bits_int>`

Enter the number of bits of the prime number used in the Diffie-Hellman exchange for RSA encryption of the SSL connection. Larger prime numbers are associated with greater cryptographic strength.

`ssl-http-location-conversion {enable | disable}`

Select to replace `http` with `https` in the reply's `Location` HTTP header field. For example, in the reply, `Location: http://example.com/` would be converted to `Location: https://example.com/`

`ssl-http-match-host {enable | disable}`

Select to apply `Location` conversion to the reply's HTTP header only if the host name portion of `Location` matches the request's `Host` field, or, if the `Host` field does not exist, the host name portion of the request's URI. If disabled, conversion occurs regardless of whether the host names in the request and the reply match.

For example, if host matching is enabled, and a request contains `Host: example.com` and the reply contains `Location: http://example.cc/`, the `Location` field does not match the host of the original request and

the reply's `Location` field remains unchanged. If the reply contains `Location: http://example.com/`, however, then the FortiGate unit detects the matching host name and converts the reply field to `Location: https://example.com/`.

This option appears only if `ssl-http-location-conversion` is `enable`.

`ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}`

Enter the maximum version of SSL/TLS to accept in negotiation. Support TLS 1.2 SSL offloading by specifying `tls-1.2`.

`ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1 | tls-1.2}`

Enter the minimum version of SSL/TLS to accept in negotiation. Support TLS 1.2 SSL offloading by specifying `tls-1.2`.

`ssl-send-empty-frags {enable | disable}`

Select to precede the record with empty fragments to thwart attacks on CBC IV. You might disable this option if SSL acceleration will be used with an old or buggy SSL implementation which cannot properly handle empty fragments.

`ssl-server-session-state-max <sessionstates_int>`

Enter the maximum number of SSL session states to keep for the segment of the SSL connection between the server and the FortiGate unit.

`ssl-server-session-state-timeout <timeout_int>`

Enter the number of minutes to keep the SSL session states for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

`ssl-server-session-state-type {both | count | disable | time}`

Select which method the FortiGate unit should use when deciding to expire SSL sessions for the segment of the SSL connection between the server and the FortiGate unit. This option appears only if `ssl-mode` is `full`.

- `both`: Select to expire SSL session states when either `ssl-server-session-state-max` or `ssl-server-session-state-timeout` is exceeded, regardless of which occurs first.
- `count`: Select to expire SSL session states when `ssl-server-session-state-max` is exceeded.
- `disable`: Select to keep no SSL session states.
- `time`: Select to expire SSL session states when `ssl-server-session-state-timeout` is exceeded.

SSL offloading support for Internet Explorer 6

In some cases the Internet Explorer 6 web browser may be able to access real servers. To resolve this issue, disable the `ssl-send-empty-frags` option:

```
config firewall vip
   edit vip_name
      set ssl-send-empty-frags disable
   end
```

You can disable this option if SSL acceleration will be used with an old or buggy SSL implementation that cannot properly handle empty fragments.

Disabling SSL/TLS re-negotiation

The vulnerability CVE-2009-3555 affects all SSL/TLS servers that support re-negotiation. FortiOS when configured for SSL/TLS offloading is operating as a SSL/TLS server. The IETF is working on a TLS protocol change that will fix the problem identified by CVE-2009-3555 while still supporting re-negotiation. Until that protocol change is available, you can use the `ssl-client-renegotiation` option to disable support for

SSL/TLS re-negotiation. The default value of this option is `allow`, which allows an SSL client to renegotiate. You can change the setting to `deny` to abort any attempts by an SSL client to renegotiate. If you select `deny` as soon as a `ClientHello` message indicating a re-negotiation is received from the client FortiOS terminates the TCP connection.

Since SSL offloading does not support requesting client certificates the only circumstance in which a re-negotiation is required is when more than 2^32 bytes of data are exchanged over a single handshake. If you are sure that this volume of traffic will not occur then you can disable re-negotiation and avoid any possibility of the attack described in CVE-2009-3555.

The re-negotiation behavior can be tested using OpenSSL. The OpenSSL s_client application has the feature that the user can request that it do renegotiation by typing “R”. For example, the following shows a successful re-negotiation against a FortiGate unit configured with a VIP for 192.168.2.100:443:

```
$ openssl s_client -connect 192.168.2.100:443
   CONNECTED(00000003)
   depth=1 /C=US/ST=California/L=Sunnyvale/O=Fortinet/OU=Certificate

   GET /main.c HTTP/1.0
   R
   RENEGOTIATING
19916:error:1409E0E5:SSL routines:SSL3_WRITE_BYTES:ssl handshake failure:s3_pkt.c:530:
```

Use the following command to check the SSL stats to see that the `renegotiations blocked` counter is now 1:

```
diagnose firewall vip virtual-server stats ssl
   ssl
      client
         connections total 0 active 0 max 0
         handshakes total 4 active 0 max 0 completed 4 abbreviated 0
         session states total 4 active 4 max 4
         cipher-suite failures 0
         embryonics total 0 active 0 max 0 terminated 0
         renegotiations blocked 1
      server
         connections total 0 active 0 max 0
         handshakes total 3 active 0 max 0 completed 2 abbreviated 1
         session states total 1 active 1 max 1
         cipher-suite failures 0
      internal error 0
      bad handshake length 0
      bad change cipher spec length 0
      pubkey too big 0
```

```
        persistence
          find 0 found 0 clash 0 addr 0 error 0
```

If the virtual server debug log is examined (diagnose debug appl vs -1) then at the point the re-negotiation is blocked there is a log:

```
vs ssl 12 handshake recv ClientHello
   vs ssl 12 handshake recv 1
       (0100005403014b5e056c7f573a563bebe0258c3254bbaff7046a461164f34f94f4f3d019c418000026

```

IP, TCP, and UDP load balancing

You can load balance all IP, TCP or UDP sessions accepted by the security policy that includes a load balancing virtual server with the type set to IP, TCP, or UDP. Traffic with destination IP and port that matches the virtual server IP and port is load balanced. For these protocol-level load balancing virtual servers you can select a load balance method and add real servers and health checking. However, you can't configure persistence, HTTP multiplexing and SSL offloading.

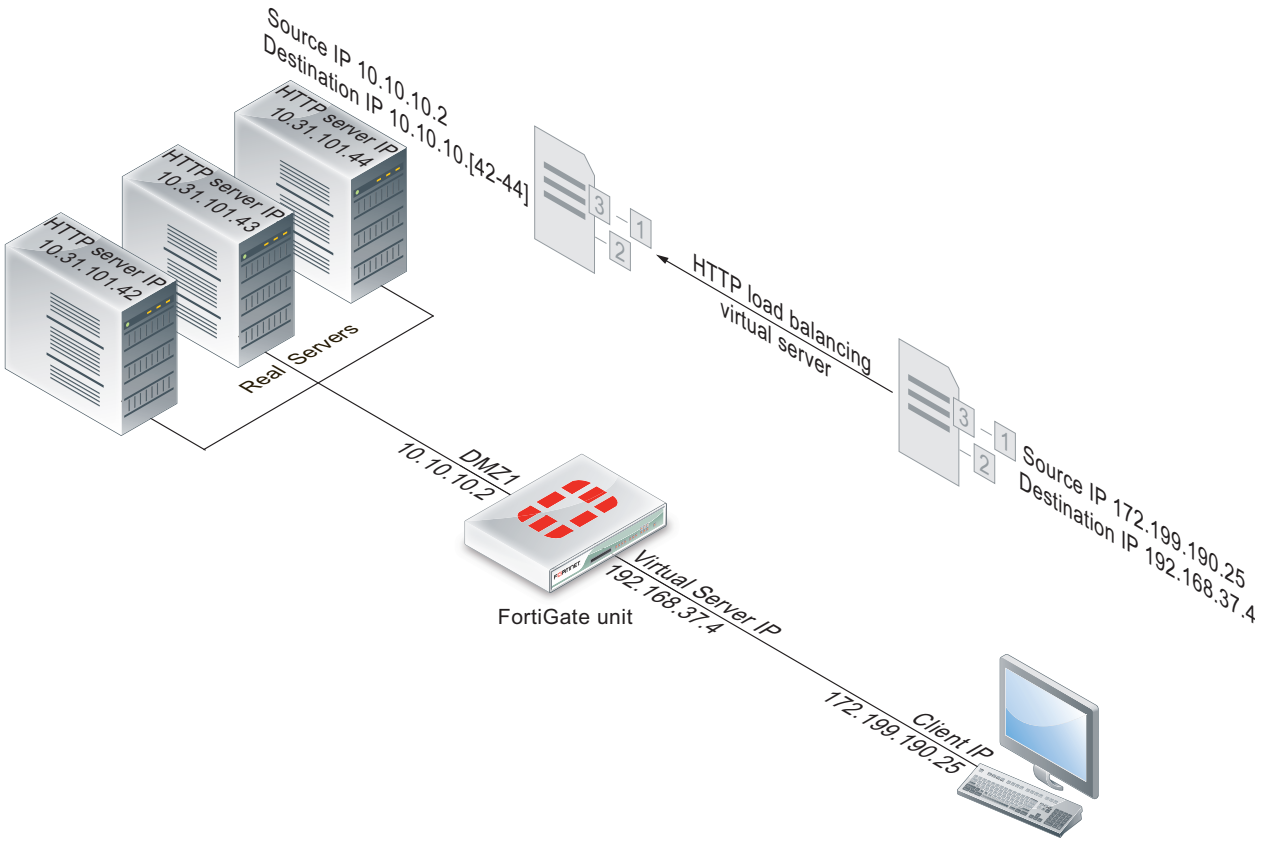
Load balancing configuration examples

Example HTTP load balancing to three real web servers

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Virtual server configuration example



Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

To add an HTTP health check monitor

In this example, the HTTP health check monitor includes the **URL** "/index.html" and the **Matched Phrase** "Fortinet products".

1. Go to **Policy & Objects > Load Balance > Health Check**.
2. Select **Create New**.
3. Add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase "Fortinet products".

Name	HTTP_health_chk_1
Type	HTTP
Port	80
URL	/index.html
Matched Content	Fortinet products
Interval	10 seconds
Timeout	2 seconds
Retry	3

4. Select **OK**.

To add the HTTP virtual server

1. Go to **Policy & Objects > Load Balance > Virtual Servers**.
2. Select **Create New**.
3. Add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

Name	Load_Bal_VS1
Type	HTTP
Interface	wan1

Virtual Server IP	192.168.37.4 The public IP address of the web server. The virtual server IP address is usually a static IP address obtained from your ISP for your web server. This address must be a unique IP address that is not used by another host and cannot be the same as the IP address of the external interface the virtual IP will be using. However, the external IP address must be routed to the selected interface. The virtual IP address and the external IP address can be on different subnets. When you add the virtual IP, the external interface responds to ARP requests for the external IP address.
Virtual Server Port	80
Load Balance Method	First Alive
Persistence	HTTP cookie
HTTP Multiplexing	Select. The FortiGate unit multiplexes multiple client into a few connections between the FortiGate unit and each real HTTP server. This can improve performance by reducing server overhead associated with establishing multiple connections.
Preserve Client IP	Select The FortiGate unit preserves the IP address of the client in the `X-Forwarded-For` HTTP header.
Health Check	Move the HTTP_health_chk_1 health check monitor to the **Selected** list.

4. Select **OK**.

To add the real servers and associate them with the virtual server

1. Go to **Policy & Objects > Load Balance > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network.
   Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.42
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.

Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.43
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP Address	10.10.10.44
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a wan1 to dmz1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the

dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Configure the security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wan1
Source Address	all (or a more specific address)
Outgoing Interface	dmz1
Destination Address	Load_Bal_VS1
Schedule	always
Service	HTTP
Action	ACCEPT
Log Allowed Traffic	Select to log virtual server traffic
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Use the following procedure to configure this load balancing setup from the CLI.

To configure HTTP load balancing

1. Use the following command to add an HTTP health check monitor that sends get requests to http://<real_server_IP_address>/index.html and searches the returned web page for the phrase “Fortinet products”.

```
config firewall ldb-monitor
   edit HTTP_health_chk_1
      set type http
      set port 80
      set http-get /index.html
      set http-match “Fortinet products”
      set interval 10
      set timeout 2
      set retry 3
   end
```

2. Use the following command to add an HTTP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate wan1 interface is connected to the Internet.

```
config firewall vip
   edit Load-Bal_VS1
      set type server-load-balance
```

```
      set server-type http
      set ldb-method first-alive
      set http-multiplex enable
      set http-ip-header enable
      set extip 192.168.37.4
      set extintf wan1
      set extport 80
      set persistence http-cookie
      set monitor HTTP_health_chk_1
         config realservers
            edit 1
               set ip 10.10.10.42
               set port 80
            next
            edit 2
               set ip 10.10.10.43
               set port 80
            next
            edit 3
               set ip 10.10.10.44
               set port 80
         end
   end
```

3. Use the following command to add a security policy that includes the load balance virtual server as the destination address.

```
config firewall policy
   edit 0
      set srcintf wan1
      set srcaddr all
      set dstintf dmz1
      set dstaddr Load-Bal_VS1
      set action accept
      set schedule always
      set service ALL
      set nat enable
   end
```

Configure other security policy settings as required.

Example Basic IP load balancing configuration

This example shows how to add a server load balancing virtual IP that load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3. The default weight is 1 and does not have to be changed for the first real server.

```
config firewall vip
   edit All_Load_Balance
      set type server-load-balance
      set server-type ip
      set extintf port2
      set extip 192.168.20.20
      set ldb-method weighted
         config realservers
            edit 1
```

```
            set ip 10.10.10.1
        next
        edit 2
            set ip 10.10.10.2
            set weight 2
        next
        edit 3
            set ip 10.10.10.3
            set weight 3
        end
end
```

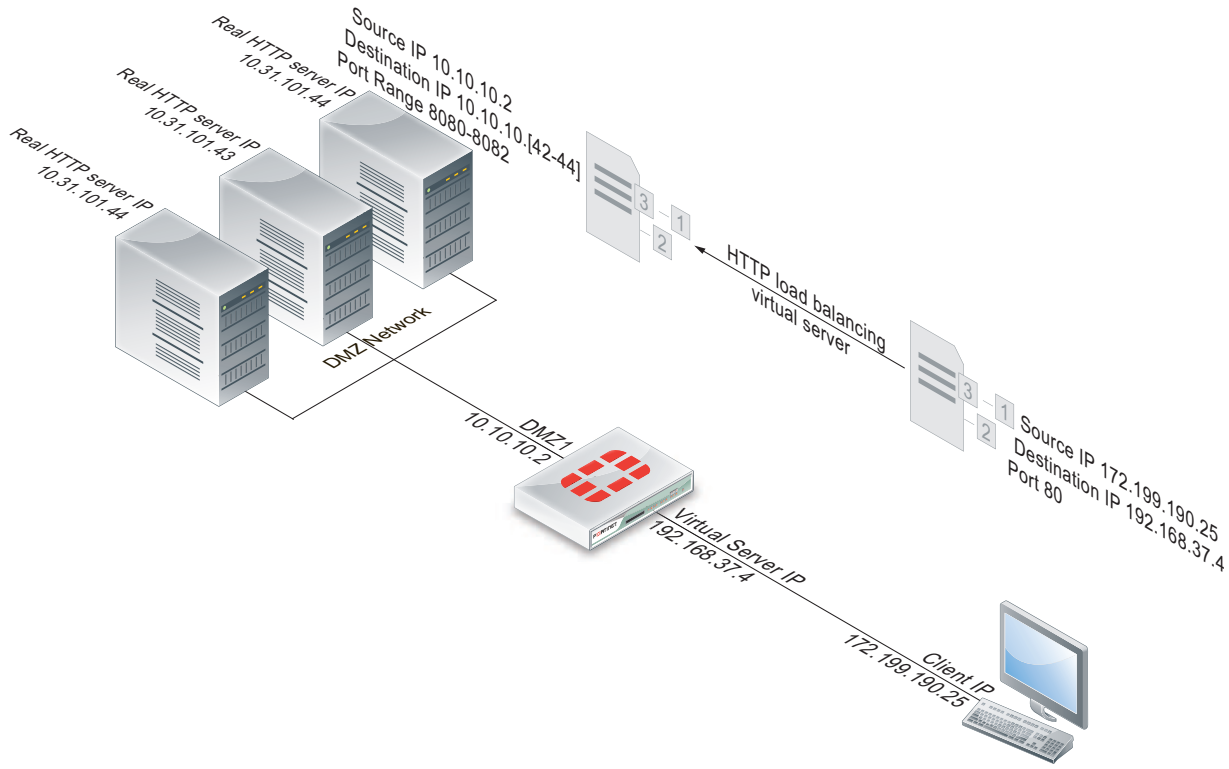
Example Adding a server load balance port forwarding virtual IP

In this example, a virtual web server with IP address 192.168.37.4 on the Internet, is mapped to three real web servers connected to the FortiGate unit dmz1 interface. The real servers have IP addresses 10.10.123.42, 10.10.123.43, and 10.10.123.44. The virtual server uses the **First Alive** load balancing method.

Each real server accepts HTTP connections on a different port number. The first real server accepts connections on port 8080, the second on port 8081, and the third on 8082. The configuration also includes an HTTP health check monitor that includes a URL used by the FortiGate unit for get requests to monitor the health of the real servers.

Connections to the virtual web server at IP address 192.168.37.4 from the Internet are translated and load balanced to the real servers by the FortiGate unit. First alive load balancing directs all sessions to the first real server. The computers on the Internet are unaware of this translation and load balancing and see a single virtual server at IP address 192.168.37.4 rather than the three real servers behind the FortiGate unit.

Server load balance virtual IP port forwarding



To complete this configuration, all of the steps would be the same as in Example HTTP load balancing to three real web servers on page 1880 except for configuring the real servers.

To add the real servers and associate them with the virtual server

Use the following steps to configure the FortiGate unit to port forward HTTP packets to the three real servers on ports 8080, 8081, and 8082.

1. Go to **Policy & Objects > Load Balance > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server Load_Bal_VS1. Each real server must include the IP address of a real server on the internal network and have a different port number.

   Configuration for the first real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.42
Port	8080
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the second real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.43
Port	8081
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the third real server.

Virtual Server	Load_Bal_VS1
IP	10.10.10.44
Port	8082
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Example Weighted load balancing configuration

This example shows how to using firewall load balancing to load balances all traffic among 3 real servers. In the example the Internet is connected to `port2` and the virtual IP address of the virtual server is 192.168.20.20. The load balancing method is `weighted`. The IP addresses of the real servers are 10.10.10.1, 10.10.10.2, and 10.10.10.3. The weights for the real servers are 1, 2, and 3.

This configuration does not include a health check monitor.

Web-based manager configuration

Use the following procedures to configure this load balancing setup from the web-based manager.

To add the HTTP virtual server

1. Go to **Policy & Objects > Load Balance > Virtual Servers**.
2. Select **Create New**.
3. Add an IP virtual server that allows users on the Internet to connect to the real servers on the internal network. In this example, the FortiGate port2 interface is connected to the Internet.

Name	HTTP_weghted_LB
Type	IP
Interface	port2
Virtual Server IP	192.168.20.20
Load Balance Method	Weighted

   All other virtual server settings are not required or cannot be changed.

4. Select **OK**.

To add the real servers and associate them with the virtual server

1. Go to **Policy & Objects > Load Balance > Real Servers**.
2. Select **Create New**.
3. Configure three real servers that include the virtual server All_Load _Balance. Because the **Load Balancing Method** is **Weighted**, each real server includes a weight. Servers with a greater weight receive a greater proportion of forwarded connections,

   Configuration for the first real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.1
Port	Cannot be configured because the virtual server is an IP server.
Weight	1

Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the second real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.2
Port	Cannot be configured because the virtual server is an IP server.
Weight	2
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

Configuration for the third real server.

Virtual Server	HTTP_weghted_LB
IP Address	10.10.10.3
Port	Cannot be configured because the virtual server is an IP server.
Weight	3
Maximum Connections	0 Setting **Maximum Connections** to 0 means the FortiGate unit does not limit the number of connections to the real server. Since the virtual server uses **First Alive** load balancing you may want to limit the number of connections to each real server to limit the traffic received by each server. In this example, the **Maximum Connections** is initially set to 0 but can be adjusted later if the real servers are getting too much traffic.

To add the virtual server to a security policy

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Configure the security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all (or a more specific address)
Outgoing Interface	port1
Destination Address	HTTP_weghted_LB
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.

CLI configuration

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`. The default weight is 1 and does not have to be changed for the first real server.

Use the following command to add the virtual server and the three weighted real servers.

```
config firewall vip
   edit HTTP_weghted_LB
      set type server-load-balance
      set server-type ip
      set extintf port2
      set extip 192.168.20.20
      set ldb-method weighted
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
               set weight 2
            next
            edit 3
               set ip 10.10.10.3
               set weight 3
            end
   end
```

Example HTTP and HTTPS persistence configuration

This example shows how to add a virtual server named **HTTP_Load_Balance** that load balances HTTP traffic using port 80 and a second virtual server named **HTTPS_Load_Balance** that load balances HTTPS traffic using port 443. The Internet is connected to port2 and the virtual IP address of the virtual server is 192.168.20.20. Both server load balancing virtual IPs load balance sessions to the same three real servers with IP addresses 10.10.10.2, 10.10.10.2, and 10.10.10.3. The real servers provide HTTP and HTTPS services.

For both virtual servers, persistence is set to **HTTP Cookie** to enable HTTP cookie persistence.

To add the HTTP and HTTPS virtual servers

1. Go to **Policy & Objects > Load Balance > Virtual Servers**.
2. Add the HTTP virtual server that includes HTTP Cookie persistence.

Name	HTTP_Load_Balance
Type	HTTP
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	80 In this example the virtual server uses port 8080 for HTTP sessions instead of port 80.
Load Balance Method	Static
Persistence	HTTP cookie

3. Select **OK**.
4. Select **Create New**.
5. Add the HTTPs virtual server that also includes HTTP Cookie persistence.

Name	HTTPS_Load_Balance
Type	HTTPS
Interface	port2
Virtual Server IP	192.168.20.20
Virtual Server Port	443
Load Balance Method	Static
Persistence	HTTP cookie

6. Select **OK**.

To add the real servers and associate them with the virtual servers

1. Go to **Policy & Objects > Load Balance > Real Servers**.
2. Select **Create New**.
3. Configure three real servers for HTTP that include the virtual server HTTP_Load_Balance.

   Configuration for the first HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.1
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the second HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.2
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

   Configuration for the third HTTP real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.3
Port	80
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

4. Configure three real servers for HTTPS that include the virtual server HTTPS_Load_Balance.

   Configuration for the first HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.1

Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the second HTTPS real server.

Virtual Server	HTTP_Load_Balance
IP Address	10.10.10.2
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

Configuration for the third HTTPS real server.

Virtual Server	HTTPS_Load_Balance
IP Address	10.10.10.3
Port	443
Weight	Cannot be configured because the virtual server does not include weighted load balancing.
Maximum Connections	0

To add the virtual servers to security policies

Add a port2 to port1 security policy that uses the virtual server so that when users on the Internet attempt to connect to the web server's IP address, packets pass through the FortiGate unit from the wan1 interface to the dmz1 interface. The virtual IP translates the destination address of these packets from the virtual server IP address to the real server IP addresses.

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select **Create New**.
3. Configure the HTTP security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all
Outgoing Interface	port1

Destination Address	HTTP_Load_Balance
Schedule	always
Service	HTTP
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

4. Select other security policy options as required.
5. Select **OK**.
6. Select **Create New**.
7. Configure the HTTP security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	HTTPS_Load_Balance
Schedule	always
Service	HTTPS
Action	ACCEPT
Enable NAT	Select this option and select **Use Destination Interface Address**.

8. Select other security policy options as required.
9. Select **OK**.

CLI configuration: adding persistence for a specific domain

Load balancing is configured from the CLI using the `config firewall vip` command and by setting `type` to `server-load-balance`.

For the CLI configuration, both virtual servers include setting `http-cookie-domain` to `.example.org` because HTTP cookie persistence is just required for the `example.org` domain.

First, the configuration for the HTTP virtual IP:

```
config firewall vip
   edit HTTP_Load_Balance
      set type server-load-balance
      set server-type http
      set extport 8080
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
```

```
      set http-cookie-domain .example.org
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
            next
            edit 3
               set ip 10.10.10.3
            end
   end
```

Second, the configuration for the HTTPS virtual IP. In this configuration you don't have to set `extport` to `443` because `extport` is automatically set to `443` when `server-type` is set to `https`.

```
config firewall vip
   edit HTTPS_Load_Balance
      set type server-load-balance
      set server-type https
      set extport 443
      set extintf port2
      set extip 192.168.20.20
      set persistence http-cookie
      set http-cookie-domain .example.org
         config realservers
            edit 1
               set ip 10.10.10.1
            next
            edit 2
               set ip 10.10.10.2
            next
            edit 3
               set ip 10.10.10.3
            end
   end
```

Chapter 18 - Logging and Reporting

This FortiOS Handbook chapter contains the following sections:

Logging and reporting overview provides general information about logging. We recommend that you begin with this chapter as it contains information for both beginners and advanced users as well. It contains an explanation of log messages, files, and devices, and an overview of the Reporting functions.

Logging and reporting for small networks provides an overview of setting up a small network for logging, with a look at a possible setup with a backup solution and a customized report.

Logging and reporting for large networks provides an overview of setting up a larger, enterprise-level network, with configuration of multiple FortiGate units, multiple FortiAnalyzer units as a backup solution, and a sample procedure for creating a more intensive and broad report to suit the larger network.

Advanced logging provides a series of separate tutorials for possible tasks and procedures an advanced user may want to undertake with their FortiGate-powered network. It contains explanations of advanced backup, logging, and report solutions.

Troubleshooting and logging provides a short overview of how log messages can be used to identify and solve problems within the network, how to identify and solve logging database issues, and how to solve connection issues between FortiGate and FortiAnalyzer units.

Logging and reporting overview

Logging and reporting in FortiOS can help you in determining what is happening on your network, as well as informing you of certain network activity, such as detection ofa virus or IPsec VPN tunnel errors. Logging and reporting go hand in hand, and can become a valuable tool for information as well as helping to show others the activity that is happening on the network.

This section explains logging and reporting features that are available in FortiOS, and how they can be used to help you manage or troubleshoot issues. This includes how the FortiGate unit records logs, what a log message is, and what the log database is.

What is logging?

Logging records the traffic passing through the FortiGate unit to your network and what action the FortiGate unit took during its scanning process of the traffic. This recorded information is called a log message.

After a log message is recorded, it is stored within a log file which is then stored on a log device. A log device is a central storage location for log messages. The FortiGate unit supports several log devices, such as FortiAnalyzer units, the FortiCloud service, and Syslog servers. A FortiGate unit's system memory and local disk can also be configured to store logs, and because of this, are also considered log devices.

You must subscribe to FortiCloud before you will be able to configure the FortiGate unit to send logs to a FortiCloud server.

When the recorded activity needs to be read in a more human way, the FortiGate unit can generate a Report. A report gathers all the log information that is needed for the report, and presents it in a graphical format, with customizable design and automatically generated charts. Reports can be used to present a graphical representation of what is going on in the network. Reports can also be generated on a FortiAnalyzer unit; if you want to generate reports on a FortiAnalyzer, see the FortiAnalyzer Setup and Administration Guide to help you create and generate those reports.

How the FortiGate unit records log messages

The FortiGate unit records log messages in a specific order, storing them on a log device. The order of how the FortiGate unit records log messages is as follows:

1. Incoming traffic is scanned.
2. During the scanning process, the FortiGate unit performs necessary actions, and simultaneously records the actions and results.
3. Log messages are sent to the log device.

Example: How the FortiGate unit records a DLP event

1. The FortiGate unit receives incoming traffic and scans for any matches associated within its firewall policies containing a DLP sensor.

2. A match is found; the DLP sensor, dlp_sensor, had a rule within it called All-HTTP with the action Exempt applied to the rule. The sensor also has Enable Logging selected, which indicates to the FortiGate unit that the activity should be recorded and placed in the DLP log file.
3. The FortiGate unit exempts the match, and places the recorded activity (the log message) within the DLP log file.
4. According to the log settings that were configured, logs are stored on the FortiGate unit's local hard drive. The FortiGate unit places the DLP log file on the local hard drive.

FortiOS features available for logging

Logs record FortiGate activity, providing detailed information about what is happening on your network. This recorded activity is found in log files, which are stored on a log device. However, logging FortiGate activity requires configuring certain settings so that the FortiGate unit can record the activity. These settings are often referred to as log settings, and are found in most security profiles, but also in **Log & Report > Log Config > Log Settings**.

Log settings provide the information that the FortiGate unit needs so that it knows what activities to record. This topic explains what activity each log file records, as well as additional information about the log file, which will help you determine what FortiGate activity the FortiGate unit should record.

Traffic

Traffic logs record the traffic that is flowing through your FortiGate unit. Since traffic needs firewall policies to properly flow through the unit, this type of logging is also referred to as firewall policy logging. Firewall policies control all traffic that attempts to pass through the FortiGate unit, between FortiGate interfaces, zones and VLAN sub-interfaces.

Logging traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic)
- packet comes into an inbound interface
- a possible log packet is sent regarding a match in the firewall policy, such as a URL filter
- traffic log packet is sent, per firewall policy
- packet passes and is sent out an interface

Traffic log messages are stored in the traffic log file. Traffic logs can be stored any log device, even system memory.

All security profile-related logs are now tracked within the Traffic logs, as of FortiOS 5.0, so all forward traffic can be searched in one place, such as if you are looking to see all activity from a particular address, security feature or traffic. Security profile logs are still tracked separately in the **Security Log** section, which only appears when logs exist.

If you have enabled and configured WAN Optimization, you can enable logging of this activity in the CLI using the `config wanopt setting` command. These logs contain information about WAN Optimization activity and are found in the traffic log file. When configuring logging of this activity, you must also enable logging within the security policy itself, so that the activity is properly recorded.

Sniffer

The Sniffer log records all traffic that passes through a particular interface that has been configured to act as a One-Armed Sniffer, so it can be examined separately from the rest of the Traffic logs.

Other Traffic

The traffic log also records interface traffic logging, which is referred to as Other Traffic. Other Traffic is enabled only in the CLI. When enabled, the FortiGate unit records traffic activity on interfaces as well as firewall policies. Logging Other Traffic puts a significant system load on the FortiGate unit and should be used only when necessary.

Logging other traffic works in the following way:

- firewall policy has logging enabled on it (Log Allowed Traffic) and other-traffic
- packet comes into an interface
- interface log packet is sent to the traffic log that is enabled on that particular interface
- possible log packet is sent regarding a match in the firewall policy, such as URL filter
- interface log packet is sent to the traffic log if enabled on that particular interface
- packet passes and is sent out an interface
- interface log packet is sent to traffic (if enabled) on that particular interface

Event

The event log records administration management as well as FortiGate system activity, such as when a configuration has changed, admin login, or high availability (HA) events occur. Event logs are an important log file to record because they record FortiGate system activity, which provides valuable information about how your FortiGate unit is performing.

Event logs help you in the following ways:

- keeping track of configuration setting changes
- IPsec negotiation, SSL VPN and tunnel activity
- quarantine events, such as banned users
- system performance
- HA events and alerts
- firewall authentication events
- wireless events on models with WiFi capabilities
- activities concerning modem and internet protocols L2TP, PPP and PPPoE
- VIP activities
- AMC disk's bypass mode
- VoIP activities that include SIP and SCCP protocols.

The FortiGate unit records event logs only when events are enabled.

Traffic Shaping

Traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings can be applied to a firewall policy, appearing within the traffic log messages.

By enabling this feature, you can see what traffic shaping, per-IP traffic shaping and reverse direction traffic shaping settings are being used.

Data Leak Prevention

Data Leak Prevention logs, or DLP logs, provide valuable information about the sensitive data trying to get through to your network as well as any unwanted data trying to get into your network. The DLP rules within a DLP sensor can log the following traffic types:

- email (SMTP, POP3 or IMAP; if SSL content SMTPS, POP3S, and IMAPS)
- HTTP
- HTTPS
- FTP
- NNTP
- IM

A DLP sensor must have log settings enabled for each DLP rule and compound rule, as well as applied to a firewall policy so that the FortiGate unit records this type of activity. A DLP sensor can also contain archiving options, which these logs are then archived to the log device.

NAC Quarantine

Within the DLP sensor, there is an option for enabling NAC Quarantine. The NAC Quarantine option allows the FortiGate unit to record details of DLP operation that involve the ban and quarantine actions, and sends these to the event log file. The NAC Quarantine option must also be enabled within the Event Log settings. When enabling NAC quarantine within a DLP Sensor, you must enable this in the CLI because it is a CLI-only command.

Media Access Control (MAC) Address

MAC address logs provide information about MAC addresses that the FortiGate unit sees on the network as well as those removed from the network. These log messages are stored in the event log (as subtype network; you can view these log messages in **Log & Report > Event Log**) and are, by default, disabled in the CLI. You can enable logging MAC addresses using the following command syntax:

```
config log setting
   set neighbor-event enable
end
```

When enabled, a new log message is recorded every time a MAC address entry is added to the ARP table, and also when a MAC address is removed as well. A MAC address log message is also recorded when MAC addresses are connected to the local switch, or from a FortiAP or FortiSwitch unit.

Application control

Application control logs provide detailed information about the traffic that internet applications such as Skype are generating. The application control feature controls the flow of traffic from a specific application, and the FortiGate unit examines this traffic for signatures that the application generates.

The log messages that are recorded provide information such as the type of application being used (such as P2P software), and what type of action the FortiGate unit took. These log messages can also help you to determine the top ten applications that are being used on your network. This feature is called application control monitoring and you can view the information from a widget on the Executive Summary page.

The application control list that is used must have logging enabled within the list, as well as logging enabled within each application entry. Each application entry can also have packet logging enabled. Packet logging for application control records the packet when an application type is identified, similar to IPS packet logging.

Logging of application control activity can only be recorded when an application control list is applied to a firewall policy, regardless of whether or not logging is enabled within the application control list.

Antivirus

Antivirus logs are recorded when, during the antivirus scanning process, the FortiGate unit finds a match within the antivirus profile, which includes the presence of a virus or grayware signature. Antivirus logs provide a way to understand what viruses are trying to get in, as well as additional information about the virus itself, without having to go to the FortiGuard Center and do a search for the detected virus. The link is provided within the log message itself.

These logs provide valuable information such as:

- the name of the detected virus
- the name of the oversized file or infected file
- the action the FortiGate unit took, for example, a file was blocked
- URL link to the FortiGuard Center which gives detailed information about the virus itself

The antivirus profile must have log settings enabled within it so that the FortiGate unit can record this activity, as well as having the antivirus profile applied to a firewall policy.

Web Filter

Web filter logs record HTTP traffic activity. These log messages provide valuable and detailed information about this particular traffic activity on your network. Web filtering activity is important to log because it can inform you about:

- what types of web sites employees are accessing
- users attempting to access banned web sites and how often this occurs
- network congestion due to employees accessing the Internet at the same time
- web-based threats resulting from users visiting non-business-related web sites

Web Filter logs are an effective tool to help you determine if you need to update your web filtering settings within a web filter profile due to unforeseen threats or network congestion. These logs also inform you about web filtering quotas that have been configured for filtering HTTP traffic.

You must configure logging settings within the web filter profile and apply the filter to a firewall policy so that the FortiGate unit can record the activity.

IPS (attack)

IPS logs, also referred to as attack logs, record attacks that occurred against your network. Attack logs contain detailed information about whether the FortiGate unit protected the network using anomaly-based defense settings or signature-based defense settings, as well as what the attack was.

The IPS or attack log file is especially useful because the log messages that are recorded contain a link to the FortiGuard Center, where you can find more information about the attack. This is similar to antivirus logs, where a link to the FortiGuard Center is provided as well that informs you of the virus that was detected by the FortiGate unit.

An IPS sensor with log settings enabled must be applied to a firewall policy so that the FortiGate unit can record the activity.

Packet logs

When you enable packet logging within an IPS signature override or filter, the FortiGate unit examines network packets, and if a match is found, saves them to the attack log. Packet logging is designed to be used as a diagnostic tool that can focus on a narrow scope of diagnostics, rather than a log that informs you of what is occurring on your network.

You should use caution when enabling packet logging, especially within IPS filters. Filter configuration that contains thousands of signatures could potentially cause a flood of saved packets, which would take up a lot of storage space on the log device. It would also take a great deal of time to sort through all the log messages, as well as consume considerable system resources to process.

You can archive packets, but you must enable this option on the Log Settings page. If your log configuration includes multiple FortiAnalyzer units, packet logs are only sent to the primary (first) FortiAnalyzer unit. Sending packet logs to the other FortiAnalyzer units is not supported.

Email filter

Email filter logs, also referred to as spam filter logs, records information regarding the content within email messages. For example, within an email filter profile, a match is found that finds the email message to be considered spam.

Email filter logs are recorded when the FortiGate unit finds a match within the email filter profile and logging settings are enabled within the profile.

Archives (DLP)

Recording DLP logs for network use is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Archived logs are usually saved for historical use and can be accessed at any time. IPS packet logs can also be archived, within the Log Settings page.

You can start with the two default DLP sensors that have been configured specifically for archiving log data, Content_Archive and Content_Summary. They are available in **Security Profiles > Data Leak Prevention**. Content_Archive provides full content archiving, while Content_Summary provides summary archiving. For more information about how to configure DLP sensors, see the Security Features chapter of the FortiOS Handbook.

You must enable the archiving to record log archives. Logs are not archived unless enabled, regardless of whether or not the DLP sensor for archiving is applied to the firewall policy.

Network scan

Network scan logs are recorded when a scheduled scan of the network occurs. These log messages provide detailed information about the network's vulnerabilities regarding software, as well as the discovery of any further vulnerabilities.

A scheduled scan must be configured and logging enabled within the Event Log settings, for the FortiGate unit to record these log messages.

Log messages

Log messages are recorded by the FortiGate unit, giving you detailed information about the network activity. Each log message has a unique number that helps identify it, as well as containing fields; these fields, often called log fields, organize the information so that it can be easily extracted for reports.

These log fields are organized in such a way that they form two groups: the first group, made up of the log fields that come first, is called the log header. The log header contains general information, such as the unique log identification and date and time that indicates when the activity was recorded. The log body is the second group, and contains all the other information about the activity. There are no two log message bodies that are alike, however, there may be fields common to most log bodies, such as the `srcintf` or `identidix` log fields.

The log header also contains information about the log priority level which is indicated in the `level` field. The priority level indicates the immediacy and the possible repercussions of the logged action. For example, if the field contains 'alert', you need to take immediate action with regards to what occurred. There are six log priority levels.

The log severity level is the level at and above which the FortiGate unit records logs. The log severity level is defined by you when configuring the logging location. The FortiGate unit will log all messages at and above the priority level you select. For example, if you select Error, the unit will log only Error, Critical, Alert, and Emergency level messages.

Log priority levels

Levels	Description
0 - Emergency	The system has become unstable.
1 - Alert	Immediate action is required.
2 - Critical	Functionality is affected.
3 - Error	An error condition exists and functionality could be affected.
4 - Warning	Functionality could be affected.
5 - Notification	Information about normal events.
6 - Information	General information about system operations.

The Debug priority level, not shown above, is rarely used. It is the lowest log priority level and usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly.

Example log header fields

Log header	
date=(2010-08-03)	The year, month and day of when the event occurred in yyyy-mm-dd format.
time=(12:55:06)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
log_id=(2457752353)	A five or ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(dlp)	The section of system where the event occurred.
subtype=(dlp)	The subtype category of the log message.
level=(notice)	The priority level of the event. See the table above.
vd=(root)	The name of the virtual domain where the action/event occurred in. If no virtual domains exist, this field always contains root.

Example log body fields

Log body	
policyid=(1)	The ID number of the firewall policy that applies to the session or packet. Any policy that is automatically added by the FortiGate will have an index number of zero.
identidx=(0)	The identity-based policy identification number. This field displays zero if the firewall policy does not use an identity-based policy; otherwise, it displays the number of the identity-based policy entry that the traffic matched. This number is not globally unique, it is only locally unique within a given firewall policy.
sessionid=(311)	The serial number of the firewall session of which the event happened.
srcip=(10.10.10.1)	The source IP address.
srcport=(1190)	The source port number.
srcintf=(internal)	The source interface name.
dstip=(192.168.1.122)	The destination IP address.
dstport=(80)	The destination port number.
dstintf=(wan1)	The destination interface name.
service=(https)	The IP network service that applies to the session or packet. The services displayed correspond to the services configured in the firewall policy.
status=(detected)	The action the FortiGate unit took.
hostname=(example.com)	The home page of the web site.
url=(/image/trees_pine_ forest/)	The URL address of the web page that the user was viewing.
msg=(data leak detected (Data Leak Prevention Rule matched)	Explains the FortiGate activity that was recorded. In this example, the data leak that was detected matched the rule, All-HTTP, in the DLP sensor.
rulename=(All-HTTP)	The name of the DLP rule within the DLP sensor.
action=(log-only)	The action that was specified within the rule. In some rules within sensors, you can specify content archiving. If no action type is specified, this field display log-only.
severity=(1)	The level of severity for that specific rule.

Logs from other devices, such as the FortiAnalyzer unit and Syslog server, contain a slightly different log header. For example, when viewing FortiGate log messages on the FortiAnalyzer unit, the log header contains the following log fields when viewed in the Raw format:

```
itime=1302788921 date=20110401 time=09:04:23 devname=FG50BH3G09601792 device_
    id=FG50BH3G09601792 log_id=0100022901 type=event subtype=system level=notice vd=root
```

The log body contains the rest of the information of the log message, and this information is unique to the log message itself.

For detailed information on all log messages, see the *FortiGate Log Message Reference*.

Explanation of a debug log message

Debug log messages are only generated if the log severity level is set to Debug. The Debug severity level is the lowest log severity level and is rarely used. This severity level usually contains some firmware status information that is useful when the FortiGate unit is not functioning properly. Debug log messages are generated by all types of FortiGate features.

The following is an example of a debug log message:

```
date=2010-01-25 time=17:25:54 logid=9300000000 type=webfilter subtype=urlfilter
    level=debug msg="found in cache"
```

Example of a Debug log message

Debug log	
date=(2010-01-25)	The year, month and day of when the event occurred in the format yyyy-mm-dd.
time=(17:25:54)	The hour, minute and second of when the event occurred in the format hh:mm:ss.
logid=(93000000000)	A ten-digit unique identification number. The number represents that log message and is unique to that log message. This ten-digit number helps to identify the log message.
type=(webfilter)	The section of system where the event occurred. There are eleven log types in FortiOS 5.2.
subtype=(urlfilter)	The subtype of the log message. This represents a policy applied to the FortiGate feature in the firewall policy.
level=(debug)	The priority level of the event. There are six priority levels to specify.
msg=("found in cache")	Explains the activity or event that the FortiGate unit recorded.

Viewing log messages and archives

Depending on the log device, you may be able to view logs within the web-based manager or CLI on the FortiGate unit. If you have configured a FortiAnalyzer unit, local hard disk, or system memory, you can view log messages from within the web-based manager or CLI. If you have configured either a Syslog or WebTrends server, you will not be able to view log messages from the web-based manager or CLI. There is also no support for viewing log messages stored on a FortiCloud server, from the FortiGate unit's web-based manager or CLI.

You do not have to view log messages from only the web-based manager. You can view log messages from the CLI as well, using the `execute log display` command. This command allows you to see specific log messages that you already configured within the `execute log filter` command. The `execute log filter` command configures what log messages you will see, how many log messages you can view at one time (a maximum of 1000 lines of log messages), and the type of log messages you can view. For more information about viewing log messages in the CLI, see "Viewing logs from the CLI".

There are two log viewing options in FortiOS: Format and Raw. The Raw format displays logs as they appear within the log file. You can view log messages in the Raw format using the CLI or a text editor, such as Notepad. Format is in a more human-readable format, and you can easily filter information when viewing log messages this way. The Format view is what you see when viewing logs in the web-based manager.

When you download the log messages from within the log message page (for example, **Log & Report > Traffic Log > Forward Traffic**), you are downloading log messages in the Raw format.

Viewing log messages in detail

From any log page, you can view detailed information about the log message in the log viewer table, located (by default) at the bottom of the page. Each page contains this log viewer table. The Log Viewer Table can contain the Archive tab, which allows you to see the archived version of the log message. The Archive tab only displays the archived log's details if archiving is enabled and logs are being archived by the FortiGate unit, but archived logs will also be recorded when using a FortiAnalyzer unit or the FortiCloud service.

When you are viewing traffic log messages, some of the categories (such as 'Application Name') have entries that can be selected to open a dialog box containing FortiGuard information about the entry. From within the dialog box, you can select the Reference link and go directly to the corresponding FortiGuard page, which contains additional information.

Viewing logs in Raw format allows you to view all log fields at once, as well as have a log file available regardless of whether you are archiving logs or not. You download the log file by selecting **Download Raw Log**. The log file is named in the following format: <log_type><log_location><log_date/time>.<log_number>.log. For example, SystemEventLog-disk-2012-09-19T12_13_46.933949.log, which is an event log. The time period is the day and month of when the log was downloaded, not the time period of the log messages within the file itself.

Quarantine

Within the Log & Report menu, you can view detailed information about each quarantined file. The information can either be sorted or filtered, depending on what you want to view.

You must enable quarantine settings within an antivirus profile and the destination must be configured in the CLI using the `config antivirus quarantine` command. The destination can be either a FortiAnalyzer unit or local disk.

Sort the files by file name, date, service, status, duplicate count (DC), or time to live (TTL). Filter the list to view only quarantined files with a specific status or from a specific service.

On **Log & Report > Security Log > Quarantine**, the file quarantine list displays the following information about each quarantined file.

Quarantine page

Lists all files that are considered quarantined by the unit. On this page you can filter information so that only specific files are displayed on the page.

GUI Item	Description
Source	Either **FortiAnalyzer** or **Local Disk**, depending where you configure to quarantined files to be stored.
Sort by	Sort the list. Choose from: **Status**, **Service**, **File Name**, **Date**, **TTL**, or **Duplicate Count**. Select **Apply** to complete the sort.
Filter	Filter the list. Choose either **Status** (infected, blocked, or heuristics) or **Service** (IMAP, POP3, SMTP, FTP, HTTP, MM1, MM3, MM4, MM7, IM, or NNTP). Select **Apply** to complete the filtering. Heuristics mode is configurable through the CLI only. If your unit supports SSL content scanning and inspection Service can also be IMAPS, POP3S, SMTPS, or HTTPS. For more information, see the Security Features chapter of the FortiOS Handbook.
Apply	Select to apply the sorting and filtering selections to the list of quarantined files.
Delete	Select to delete the selected files.
Page Controls	Use the controls to page through the list.
Remove All Entries	Removes all quarantined files from the local hard disk. This icon only appears when the files are quarantined to the hard disk.
File Name	The file name of the quarantined file. When a file is quarantined, all spaces are removed from the file name, and a 32-bit checksum is performed on the file. The checksum appears in the replacement message but not in the quarantined file. The file is stored on the FortiGate hard disk with the following naming convention: <32bit_CRC>.<processed_filename> For example, a file named Over Size.exe is stored as 3fc155d2.oversize.exe.
Date	The date and time the file was quarantined, in the format dd/mm/yyyy hh:mm. This value indicates the time that the first file was quarantined if duplicates are quarantined.
Service	The service from which the file was quarantined (HTTP, FTP, IMAP, POP3, SMTP, MM1, MM3, MM4, MM7, IM, NNTP, IMAPS, POP3S, SMTPS, or HTTPS).
Status	The reason the file was quarantined: **infected**, **heuristics**, or **blocked**.
Status Description	Specific information related to the status, for example, “File is infected with “W32/Klez.h”” or “File was stopped by file block pattern.”

GUI Item	Description
DC	Duplicate count. A count of how many duplicates of the same file were quarantined. A rapidly increasing number can indicate a virus outbreak.
TTL	Time to live in the format hh:mm. When the TTL elapses, the FortiGate unit labels the file as EXP under the TTL heading. In the case of duplicate files, each duplicate found refreshes the TTL. The TTL information is not available if the files are quarantined on a FortiAnalyzer unit.
Upload status	**Y** indicates the file has been uploaded to Fortinet for analysis, **N** indicates the file has not been uploaded. This option is available only if the FortiGate unit has a local hard disk.
Download	Select to download the corresponding file in its original format. This option is available only if the FortiGate unit has a local hard disk.
Submit	Select to upload a suspicious file to Fortinet for analysis. This option is available only if the FortiGate unit has a local hard disk.

Customizing the display of log messages on the web-based manager

Customizing log messages on the web-based manager allows you to remove or add columns from the page and filter the information that appears. For example, you can view only log messages that appeared on December 4, between the hours of 8:00 and 8:30 am.

1. Select the submenu in **Log & Report** in which you want to customize the display of log messages, such as **Log & Report > Traffic Log > Forward Traffic**.
2. Right click on the title bar at the top of any column, and uncheck a column title such as **Date/Time** to remove it from the interface. Check other columns to add them to the interface. When you are finished, click outside the menu and the page will refresh with the new column settings in place.
3. Choose a column you'd like to filter, and select the funnel icon next to the title of the column. For example, select the funnel in the Src (Source) column. In the text field, enter the source IP address 1.1.1.1 and then select the check box beside **NOT**.
   This filters out the all log messages that have the 1.1.1.1 source IP address in the source IP log field, such as the ones generated when running log tests in the CLI.
4. Select **OK** to save the customize settings, and then view the log messages on the page.
   Log messages that originate from the 1.1.1.1 source address will no longer appear in the list.

How to download log messages and view them from on a computer

After recording some activity, you can download log messages to view them from a computer. This is can be very useful when in a remote location, or if you want to view log messages at your convenience, or to view packet logs or traffic logs.

1. In Log & Report, select the submenu that you want to download log messages from.
   For example, **Log & Report > Traffic Log> Forward Traffic**.

2. Select the **Download Raw Log** option and save the log file to your computer.
   The log file will be downloaded like any other file. Log file names contain their log type and date in the name, so it is recommended to create a folder in which to archive your log messages, as they can be sorted easily.
3. Open a text editor such as Notepad, open the log file, and then scroll to view all the log messages.
   You can easily search or scroll through the logs to see the information that is available.

Log files and types

As the log messages are being recorded, log messages are also being put into different log files. The log file contains the log messages that belong to that log type, for example, traffic log messages are put in the traffic log file.

When downloading the log file from within **Log & Report**, the file name indicates the log type and the device on which it is stored, as well as the date, time, and a unique id for that log.

This name is in the format <logtype> - <logdevice> - <date> T <time> . <id>.log.

For example, AntiVirusLog-disk-2012-09-13T11_07_57.922495.log.

Below, each of the different log files are explained. Traffic and Event logs come in multiple types, but all contain the base type such as ‘Event’ in the filename.

Log Types based on network traffic

Log Type	Description
Traffic	The traffic logs records all traffic to and through the FortiGate interface. Different categories monitor different kinds of traffic, whether it be forward, local, or sniffer.
Event	The event logs record management and activity events within the device in particular areas: System, Router, VPN, User, Endpoint, HA, WAN Opt./Cache, and WiFi. For example, when an administrator logs in or logs out of the web-based manager, it is logged both in System and in User events.
Antivirus	The antivirus log records virus incidents in Web, FTP, and email traffic.
Web Filter	The web filter log records HTTP FortiGate log rating errors including web content blocking actions that the FortiGate unit performs.
Application Control	The application log records application usage, monitoring or blocking as configured in the security profiles.
Intrusion	The intrusion log records attacks that are detected and prevented by the FortiGate unit.
Email Filter	The email filter log records blocking of email address patterns and content in SMTP, IMAP, and POP3 traffic.
Vulnerability Scan	The Vulnerability Scan (Netscan) log records vulnerabilities found during the scanning of the network.
Data Leak Prevention	The Data Leak Prevention log records log data that is considered sensitive and that should not be made public. This log also records data that a company does not want entering their network.
VoIP	The VoIP log records VoIP traffic and messages. It only appears if VoIP is enabled on the Administrator Settings page.

Log database and datasets

The log database, also known as the SQL log database, is used to store logs on FortiGate units that have a built-in hard disk. The log database uses Structured Query Lanaguage (SQL), specifically it uses SQLite which is an embedded Relational Database Management System (RDBMS).

If you have disabled SQL logging and have factory defaults on the FortiGate unit, and then you upgrade the firmware, the upgrade will automatically disable SQL logging. When this occurs, you must re-enable SQL logging manually.

The FortiGate unit creates a database table for each log type, when log data is recorded. If the FortiGate unit is not recording log data, it does not create log tables for that device.

The command syntax, `get report database schema`, allows you to view all the tables, column names and types that are available to use when creating SQL statements for datasets.

If you want to view the size of the database, as well as the log database table entries, use the `get log sql status` command. This command displays the amount of free space that is available as well as the first and last log database entry time and date.

The output of the `get log sql status` command contains information similar to the following:

```
Database size: 294912
Free size in database: 0
Database Page Size: 8192
Entry number:
Event: 49
Traffic: 370
Attack: 2
AntiVirus: 4
WebFilter: 254
AntiSpam: 2
Netscan: 18
Total: 699
First entry time: 2012-09-10 11:41:02
Last entry time: 2012-09-13 02:59:59
```

The log database is not only used to store logs, but also used to extract the information for reports. Reports are built from datasets, which are SQL statements that tell the FortiGate unit how to extract the information from the database. You can create your own datasets; however, SQL knowledge is required. Default datasets are available for reports.

Notifications about network activity

Alert email messages provide notification about activities or events logged. These email messages also provide notification about log severities that are recorded, such as a critical or emergency.

You can send alert email messages to up to three email addresses. Alert messages are also logged and can be viewed from the Event Log menu, in the System Event log file.

You can use the alert email feature to monitor logs for log messages, and to send email notification about a specific activity or event logged. For example, if you require notification about administrators logging in and out, you can configure an alert email that is sent whenever an administrator logs in and out. You can also base alert email messages on the severity levels of the logs. The FortiGate unit does not currently support SSL/TLS connections for SMTP servers, so you must choose an SMTP server that does not need SSL/TLS when configuring the SMTP server settings.

Before configuring alert email, you must configure at least one DNS server if you are configuring with an Fully Qualified Domain Server (FQDN). The FortiGate unit uses the SMTP server name to connect to the mail server, and must look up this name on your DNS server. You can also specify an IP address.

The default minimum log severity level is Alert. If the FortiGate unit collects more than one log message before an interval is reached, the FortiGate unit combines the messages and sends out one alert email.

How to configure email notifications

The following explains how to configure an alert email notification for IPsec tunnel errors, firewall authentication failure, configuration changes and FortiGuard license expiry.

1. In **System > Config > Advanced**, under **Email Service**, configure the SMTP server.
   The SMTP server settings allow the FortiGate unit to know exactly where the email will be sent from, as well as who to send it to. The SMTP server must be a server that does not support SSL/TLS connections; if the SMTP server does, the alert email configuration will not work. The FortiGate unit does not currently support SSL/TLS connections for SMTP servers.
2. In **Log & Report > Log Config > Alert E-mail**, enter the source email in the Email From field, and up to three target addresses in the Email To fields.
3. Below the email entry, you can configure the email responses. By default, the **Send alert email for the following** is enabled. Select the check boxes beside **IPsec tunnel errors**, **Configuration changes** and **Firewall authentication failure**.
   These alerts will be sent to the email address specified when the trigger occurs. For example, a user attempts to connect to the branch office of the company but cannot; the FortiGate unit detects an IPsec tunnel error, records the event, and then sends the notice to the email address specified in the SMTP server settings.
4. Select **FortiGuard license expiry time:** and then enter 10 so that the email notification will be sent ten days prior to the FortiGuard license expiration.
   You can choose up to 100 days prior to when the license will expire. The default time is 15 days. By using this alert email notification, you can easily know when to send an re-registration request long before the expiry.

Log devices

The FortiGate unit supports a variety of log devices, including the FortiCloud service and FortiAnalyzer units. This provides greater flexibility not only when choosing a log device, but also when your logging requirements need updating.

When you have developed a plan that meets your logging needs and requirements, you need to select the log device that is appropriate for that plan. A log device must be able to store all the logs you need, and if you require archiving those logs, you must consider what log devices support this option.

During this process of deciding what log device meets your needs and requirements, you must also figure out how to provide a backup solution in the event the log device that the FortiGate unit is sending logs to has become unavailable. A backup solution should be an important part of your log setup because it helps you to maintain all logs and prevents lost logs, or logs that are not sent to the log device. For example, a daily backup of log files to the FortiAnalyzer unit occurs at 5 pm.

Log devices provide a central location for storing logs recorded by the FortiGate unit. The following are log devices that the FortiGate unit supports:

- FortiGate system memory
- Hard disk or AMC
- SQL database (for FortiGate units that have a hard disk)
- FortiAnalyzer unit
- FortiCloud service
- Syslog server

These log devices, except for the FortiGate system memory and local hard disk, can also be used as a backup solution. For example, you can configure logging to the FortiGate unit's local disk, but also configure logging to a FortiCloud server and archive logs to both the FortiCloud server and a FortiAnalyzer unit.

If you are formatting a disk that contains more than just logs, all information on the disk will be lost

FortiGate unit's system memory and hard disk

The FortiGate unit's system memory and hard disk can store all log types, including log archives and traffic logs. Traffic logs and log archives are larger files, and need a lot of room when being logged by the FortiGate unit.

When the system memory is full, the FortiGate unit overwrites the oldest messages, and all log messages stored in memory are cleared when the FortiGate unit restarts. By default, logging to memory is enabled. This means that most of the time you will only need to modify the default settings to your network logging requirements. Real-time logging occurs whenever memory logging is enabled, and is enabled by default. Real-time logging means that the activity is being recorded as it happens.

All FortiGate units 100D and larger are capable of disk logging, but it is disabled by default, as it is not recommended. For flash memory-based units, constant rewrites to flash drives can reduce the lifetime and efficiency of the memory. For hard-disk units, it can affect performance under heavy strain. Therefore, disk logging must be manually enabled in the CLI under `config log disk setting` to appear in the interface at all.

Models without a hard disk are not recommended for disk logging. For all units, disk logging must be enabled in the CLI. For some low-end and older models, disk logging is unavailable. Check a product's Feature Matrix for more information. In either case, Fortinet recommends using either a FortiAnalyzer unit or the FortiCloud service.

When logging to the FortiGate unit's hard disk or memory, you can also configure logging to a FortiAnalyzer unit as well as upload logs to it at a scheduled time.

If you are registered with the FortiCloud service, your unit will log both locally and to the service by default. In order to configure the rate and time of uploads to the service, you must register a contract account for the FortiCloud service, which will also grant you additional space.

FortiAnalyzer unit

The FortiAnalyzer unit can log all FortiGate features, which includes log archives. You can also configure the FortiGate unit to upload logs to the FortiAnalyzer unit at a scheduled time.

Encryption of the logs is supported by default and logs are sent using IPsec or SSL VPN. When the FortiAnalyzer and FortiGate units have SSL encryption, both must choose a setting for the enc-algorithm command (CLI) for encryption to take place. By default, this is enabled and the default setting is a SSL communication with high and medium encryption algorithms. The setting that you choose must be the same for both.

FortiGate units can support logging to multiple FortiAnalyzer units. This logging solution is a backup redundancy solution, since logs are sent to all three units and whenever one of the FortiAnalyzer units fails, the others still carry on storing logs.

If you are using evaluation software FortiGate and FortiAnalyzer-VM images, you will only be able to use low-level encryption.

The FortiGate unit can also connect to a FortiAnalyzer unit using Automatic Discovery. Automatic Discovery is a method of establishing a connection to a FortiAnalyzer unit by using the FortiGate unit to find a FortiAnalyzer unit on the network. The Fortinet Discovery Protocol (FDP) is used to located the FortiAnalyzer unit. Both the FortiGate and FortiAnalyzer units must be on the same subnet to use FDP, and they must also be able to connect using UDP.

When you enable automatic discovery in the CLI, the FortiGate unit uses HELLO packets to locate any FortiAnalyzer units that are available on the network within the same subnet. When the FortiGate unit discovers a FortiAnalyzer unit, the FortiGate unit automatically enables logging to the FortiAnalyzer unit and begins sending log data.

Syslog server

The Syslog server is a remote computer running syslog software. Syslog is a standard for forwarding log messages in an IP network, and can be used when considering a log backup solution for your network logging requirements.

FortiGate units support the reliable syslog feature, which is based on RFC 3195. Reliable syslog logging uses TCP, which ensures that connections are set up, including that packets are transmitted.

There are several profiles available for reliable syslog, but only the RAW profile is currently supported on the FortiGate units. The RAW profile is designed to provide a high-performance, low-impact footprint using essentially the same format as the existing UDP-based syslog service. The reliable syslog feature is available on FortiGate units running FortiOS 4.0 MR1 and higher.

When enabling the reliable syslog (available only in the CLI), TCP is used. The feature is disabled by default, and when enabled, the FortiGate unit automatically changes the port number to TCP 601. This is based on RFC 3195. The default port for syslog is port 514.

How to choose a log device for your network topology

When planning the log requirements, you must also consider your network's topology and whether archiving is required, such as if there is a legal requirement to keep a historical record of network activity. The following explains what steps to take when choosing a log device for your specific network topology.

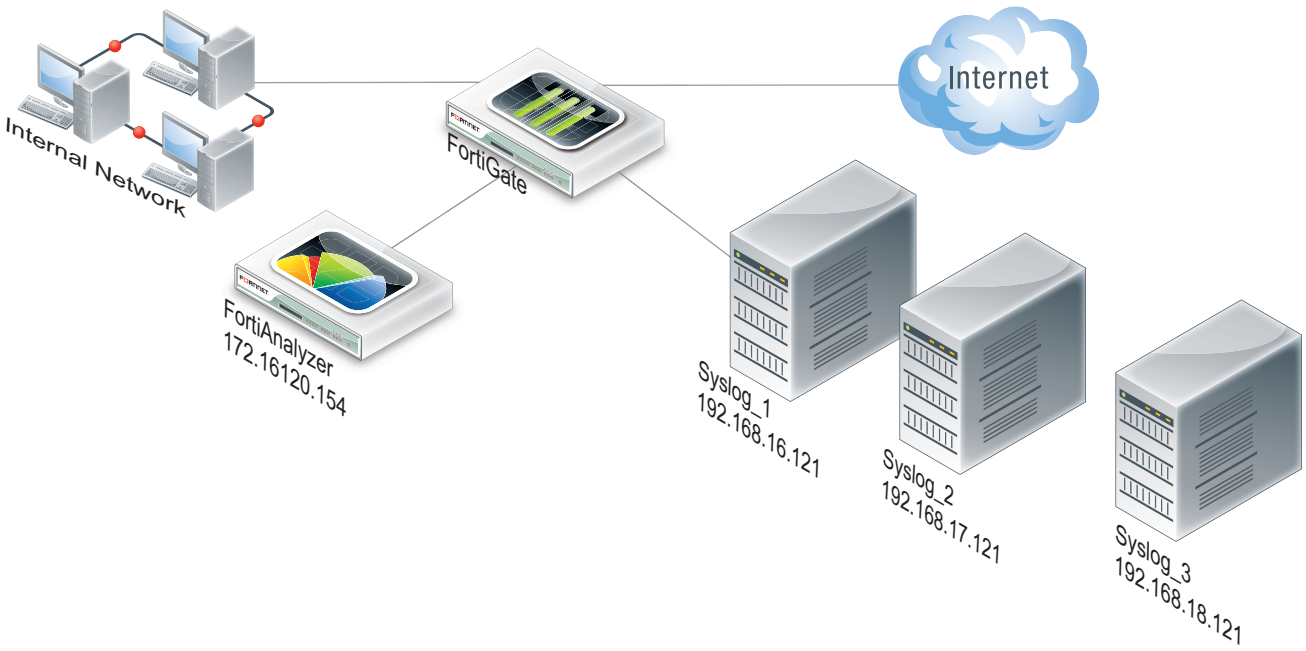
1. **What is the scope of your network topology?**
   If it is a SOHO/SMB network, then logging to the FortiGate unit's local hard disk or the default FortiCloud service would be efficient. If the network topology is a large enterprise, you will need FortiAnalyzer units, a FortiCloud contract, Syslog servers, or any combination.
2. **Is archiving required?**
   If the network activity that is being logged needs to be archived, then, depending on your network topology, you would choose a FortiAnalyzer unit. FortiAnalyzer units store archives in the same way that FortiGate units do, but are able to store large amounts of logs and archives.
3. **When troubleshooting, you may want to log a larger amount of traffic; how much storage space will you need?**
   Logs can be configured to roll, which is similar to zipping a file; this will lower the space requirements needed to contain them. You can also download logs from the FortiGate unit and save them on a server or on a computer to view and access later, to prevent them from piling up and being overwritten. If you're regularly logging large amounts of traffic, you should consider a FortiAnalyzer or FortiCloud account .
4. **Should I invest in a log device that can grow as my network grows?**
   All networks grow, so investing in a device that can grow with your network and that can be expanded is a good investment. For example, if you currently have a SOHO/SMB topology, but see growth already starting, a

FortiAnalyzer unit would be best. A FortiAnalyzer unit provides ample storage space, and you can add two more FortiAnalyzer units to access additional storage and create a redundancy log backup solution.

How to create a backup solution for logging

The following helps to explain how to create a log backup solution for a small network topology. This example has one FortiAnalyzer unit and a subscription to the FortiCloud Service.

Example of an integrated FortiAnalyzer unit and Syslog servers in a network



1. Log in to the CLI and modify what features will be logged to the FortiAnalyzer unit as well as the settings to the default log device, the FortiGate unit's hard drive.
   By default, the FortiGate unit logs to either the system memory or hard drive, whichever is available on the FortiGate unit. Low-end FortiGate units may have logging disabled by default.
2. In the CLI, use the `config log fortianalyzer setting` command to configure logging to the FortiAnalyzer unit.
   You can only configure log settings for the FortiAnalyzer unit in the CLI. Configuring to upload logs to a FortiAnalyzer unit can be configured in both the CLI and web-based manager.
3. In the CLI, configure the settings for the Syslog server; also enable reliable syslog as well.
   Reliable syslog verifies that logs are sent to the syslog server. When you enable this setting, the default port becomes port 601.

Reports

Reports provide a way to analyze log data without manually going through a large amount of logs to get to the information you need. This section explains how to configure a FortiOS report and how to modify the existing default FortiOS Security Features report. The FortiOS default Security Features report is a report that gathers security feature activity information and compiles it into a report. This section also explains how to view these reports.

Reports provide a clear, concise overview of what is happening on your network based on log data, without manually going through large amounts of logs. Reports can be configured on a FortiGate unit or a FortiAnalyzer unit. However, in this document only FortiOS reports are explained. FortiOS reports are the reports that are generated on the FortiGate unit. FortiAnalyzer reports are configured on a FortiAnalyzer unit and for information about those reports, see the FortiAnalyzer Administration Guide.

Disk or memory logging must be enabled for reporting to be enabled. Local Reporting can then be enabled in **Log & Report > Log Settings,** in order to view and edit reports.

What are FortiOS reports?

FortiOS reports are configured from logs stored on the FortiGate unit's hard drive. These reports, generated by the FortiGate unit itself, provide a central location for both configuring and generating reports. A default FortiOS report, called the FortiGate Security Feature Daily Activity Report, is available for you to modify to your requirements. The default report provides a way to quickly and easily set up your own report from within the web-based manager. The default FortiOS report is a report that compiles security feature activity from various security-related logs, such as virus and attack logs.

FortiOS reports consist of multiple parts, regardless of whether its the default FortiOS report or a report that you have configured from scratch, and these parts are configured separately and added to the layout. These parts of a FortiOS report are:

- charts (including datasets within the charts themselves)
- themes (including styles which are within the themes themselves)
- images
- layout

The parts of a FortiOS report

Charts are used to display the log information in a clear and concise way using graphs and tables. Charts contain datasets, which are SQLite queries that help the FortiGate unit to add specific log information into the chart using the log information that is stored in the SQLite database on the local hard disk. If you want to configure a chart, you must configure the dataset first. Datasets are required for each chart, and if there is no dataset included in a chart, the chart will not be saved.

Themes provide a one-step style application for report layouts. Themes contain various styles, including styles for the table of contents, headings, headers and footers, as well as the margins of the report's pages. Themes are applied to layouts. The styles that are applied to themes are configured separately in the CLI.

You can easily upload your company or organization's logo to use within a report. By uploading your company or organization's logo and applying it to a report, you provide a personalized report that is recognizable as your company or organization's report. The image must be in JPEG, JPG or PNG format.

Layouts provide a way to incorporate the charts, images, and themes that are configured to create a formatted report. A layout is used as a template by the FortiGate unit to compile and then generate the report. The layout is also coded in the CLI.

What you can do with the default FortiOS report

You can reset the reports you have configured, as well as the default FortiOS report you modified, to default settings. When you reset reports to default settings, any configured reports that you created from scratch are lost. The `execute report-config reset` command resets the reports to default settings. If you are going to

reset the reports to their default settings, you should back up the current configuration file before doing so, in the event you want to revert back to the reports you previously created and/or modified.

The default FortiOS report can be modified so that it meets your requirements for a report. This default report is located in **Log & Report > Report > Local**. Select **Customize** to edit it.

The FortiOS default report contains several pages, which appear as stacked boxes in the editing interface. Each page contains one or multiple charts (depending on the configuration of that page in the interface), and each page in the finished report will contain information about the FortiGate unit at the top of each section.

You can select **Run Now** on the **Local** page to immediately create a report with the current layout and design. More complex reports may take longer to generate. After generating a report, you can view it by selecting it from the list below **Run Now**. Historical reports will be marked as 'Scheduled' if created automatically, or 'On Demand' if created by selecting **Run Now**.

How to modify the default FortiOS report

The following is a sample modification of the default FortiOS report, which includes adding an image.

1. In **Log & Report > Report > Config**, modify the page by adding a new Chart, which will appear on its own page in the final report.
2. Add an information Text field below the chart.
   You should always save the changes you make by selecting **Save**; otherwise, the changes you just made will be lost.
3. Modify the header to add the company's image.
   The company's image will appear in all headers throughout the report. If you select **Save** now, it will appear on all the report's pages.
4. Add other charts to the list so they will appear within the report.
   Charts marked as 'FortiGate Security Feature Security Analysis Report' are autogenerated and take up an entire page or multiple pages on their own. All other charts take up half a page, so two consecutive charts will appear on the same page in the report.
5. Modify the report settings so that the report is generated every Monday at 6 pm, and is emailed to specific employees in the company.
   Reports can be sent to others after the report has been generated, if Messaging Servers are configured.
6. Test the report's modified settings, by selecting **Run Now** in the Config page; after it is generated, go to **Log & Report > Report > Local** and view the report.
   You can tell that it has been generated because the Bandwidth Usage page's charts will be populated, and the text added below each chart appears as well.

Best Practices: Log management

When the FortiGate unit records FortiGate activity, valuable information is collected that provides insight into how to better protect network traffic against attacks, including misuse and abuse. There is a lot to consider before enabling logging on a FortiGate unit, such as what FortiGate activities to enable and which log device is best suited for your network's logging needs. A plan can help you in deciding the FortiGate activities to log, a log device, as well as a backup solution in the event the log device fails.

This plan should provide you with an outline, similar to the following:

- what FortiGate activities you want and/or need logged (for example, security features)
- the logging device best suited for your network structure

- if you want or require archiving of log files
- ensuring logs are not lost in the event a failure occurs.

After the plan is implemented, you need to manage the logs and be prepared to expand on your log setup when the current logging requirements are outgrown. Good log management practices help you with these tasks.

Log management practices help you to improve and manage logging requirements. Logging is an ever-expanding tool that can seem to be a daunting task to manage. The following management practices will help you when issues arise, or your logging setup needs to be expanded.

1. Revisit your plan on a yearly basis to verify that your logging needs are being met by your current log setup. For example, your company or organization may require archival logging, but not at the beginning of your network's lifespan. Archival logs are stored on a FortiGate unit's local hard drive, a FortiAnalyzer unit, or a FortiCloud server, in increasing order of size.
2. Configure an alert message that will notify you of activities that are important to be aware about. For example: if a branch office does not have a FortiGate administrator, you will need to know at all times that the IPsec VPN tunnel is still up and running. An alert email notification message can be configured to send only if IPsec tunnel errors occur.
3. If your organization or company uses peer-to-peer programs such as Skype or other instant messaging software, use the Applications FortiView dashboard, or the Executive Summary's report widget (Top 10 Application Bandwidth Usage Per Hour Summary) to help you monitor the usage of these types of instant messaging software. These widgets can help you in determining how these applications are being used, including if there is any misuse and abuse. Their information is taken from application log messages; however, application log messages should be viewed as well since they contain the most detailed information.
4. Ensure that your backup solution is up-to-date. If you have recently expanded your log setup, you should also review your backup solution. The backup solution provides a way to ensure that all logs are not lost in the event that the log device fails or issues arise with the log device itself.

Logging and reporting for small networks

This section explains how to configure the FortiGate unit for logging and reporting in a small office or SOHO/SMB network. To properly configure this type of network, you will be modifying the default log settings, as well as the default FortiOS report.

The following procedures are examples and can be used to help you when configuring your own network's log topology. Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own network's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled, except for traffic logging. The default logging location will be either the FortiGate unit's system memory or hard disk, depending on the model. Units with a flash disk are not recommended for disk logging.

Modifying the FortiGate unit's system memory default settings

When the FortiGate unit's default log device is its system memory, the following is modified for a small network topology. The following is an example of how to modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
   set ips-archive disable
   set status enable
end
```

3. The following example command syntax modifies which FortiGate features that are enabled for logging:

```
config log memory filter
   set attack enable
   set forward-traffic enable
   set local-traffic enable
   set netscan enable
   set email-log-imap disable
   set multicast-traffic enable
   set scanerror enable
   set app-ctrl enable
end
```

Modifying the FortiGate unit's hard disk default settings

When the FortiGate unit's default log device is its hard disk, you need to modify those settings to your network's logging needs so that you can effectively log what you want logged. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
   set ips-archive disable
   set status enable
   set max-log-file-size 1000
   set storage FLASH
   set log-quota 100
   set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
   set sniffer-traffic disable
   set local-traffic enable
end
```

Testing sending logs to the log device

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a NAC QUARANTINE message with level - notification
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > Event Log > User**, and view the logs to see some of the recently generated test log messages.
   You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

A backup solution provides a way to ensure logs are not lost. The following backup solution explains logging to a FortiCloud server and uploading logs to a FortiAnalyzer unit. With this backup solution, there can be three simultaneous storage locations for logs, the first being the FortiGate unit itself, the FortiAnalyzer unit and then the FortiCloud server.

Configuring logging to a FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network’s log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **System > Dashboard > Status** and click **Login** next to **FortiCloud** in the **License Information** widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Config > Log Settings**.
5. Under the Logging and Archiving header, you can select your desired upload time.

With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Configuring uploading logs to the FortiAnalyzer unit

The logs will be uploaded to the FortiAnalyzer unit at a scheduled time. The following is an example of how to upload logs to a FortiAnalyzer unit.

To upload logs to a FortiAnalyzer unit

1. Go to **Log & Report > Log Config > Log Settings**.
2. In the **Logging and Archiving** section, select the check box beside **Send Logs to FortiAnalyzer/FortiManager.**
3. Select **FortiAnalyzer (Daily at 00:00)**.
4. Enter the FortiAnalyzer unit’s IP address in the **IP Address** field.
5. To configure the daily upload time, open the CLI.
6. Enter the following to configure when the upload occurs, and the time when the unit uploads the logs:

```
config log fortianalyzer setting
   set upload-interval {daily | weekly | monthly}
   set upload-time <hh:mm>
end
```

7. To change the upload time, in the web-based manager, select **Change** beside the upload time period, and then make the changes in the Upload Schedule window. Select **OK**.

Testing uploading logs to a FortiAnalyzer unit

You should test that the FortiGate unit can upload logs to the FortiAnalyzer unit, so that the settings are configured properly.

To test the FortiAnalyzer upload settings

1. Go to **Log & Report > Log Config > Log Settings.**
2. In the **Logging and Archiving** section, under **Send Logs to FortiAnalyzer/FortiManager**, change the time to the current time by selecting **Change**.
   For example, the current time is 11:10 am, so **Change** now has the time 11:10.
3. Select **OK**.

The logs will be immediately sent to the FortiAnalyzer unit, and will be available to view from within the FortiAnalyzer's interface.

Modifying the default FortiOS report

The default FortiOS report is provided to help you quickly and easily configure and generate a report. The following is an example of how to modify the default FortiOS report.

To modify the default FortiOS report

1. In the web-based manager, go to **Log & Report > Report > Local**.
2. Select **Customize** to open the Report Editor.
3. Change the default Fortinet image to the new image: select the Fortinet image and right-click so that **Delete** icon appears, and then select **Delete**; drag the Image icon to the box where the Fortinet image was previous; choose or upload a new image and then select **OK**.
4. Return to **Log & Report > Report > Local**.
5. Under **Report Options**, set the Generate report schedule to **Daily** and set a Time for the report to be compiled every day.
6. Enable **Email Generated Reports**. You may have to configure an SMTP server to send the reports before this option can be enabled. The SMTP configuration can be found in **System > Config > Messaging Servers**.
7. Select **Apply** to save the changes.
8. Select **Run Now** to generate a new On Demand report based on your changes.
9. Select the report from the Historical Reports list to view it.

Running On Demand reports can be a good way to compare report modifications as you configure.

Logging and reporting for large networks

This section explains how to configure the FortiGate unit for logging and reporting in a larger network, such as an enterprise network. To set up this type of network, you are modifying the default log settings, and you are also modifying the default report.

The following procedures are examples and can be used to help you when configuring your own network's log topology.

Since some of these settings must be modified or enabled or disabled in the CLI, it is recommended to review the FortiGate CLI Reference for any additional information about the commands used herein, as well as any that you would need to use in your own newtork's log topology.

Modifying default log device settings

The default log device settings must be modified so that system performance is not compromised. The FortiGate unit, by default, has all logging of FortiGate features enabled and well as logging to either the FortiGate unit's system memory or hard disk, depending on the model.

Modifying multiple FortiGate units' system memory default settings

When the FortiGate unit's default log device is its system memory, you can modify it to fit your log network topology. In this topic, the following is an example of how you can modify these default settings.

To modify the default system memory settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log memory setting
   set ips-archive disable
   set status enable
end
```

3. Enter the following command syntax to modify the FortiGate features that are enabled for logging:

```
config log memory filter
   set attack enable
   set forward-traffic enable
   set local-traffic enable
   set netscan enable
   set email-log-imap enable
   set multicast-traffic enable
   set scanerror enable
   set app-ctrl enable
end
```

4. Repeat steps 2 and 3 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Modifying multiple FortiGate units' hard disk default log settings

You will have to modify each FortiGate unit's hard disk default log settings. The following is an example of how to modify these default settings.

To modify the default hard disk settings

1. Log in to the CLI.
2. Enter the following command syntax to modify the logging settings:

```
config log disk setting
   set ips-archive disable
   set status enable
   set max-log-file-size 1000
   set storage Internal
   set log-quota 100
   set report-quota 100
end
```

3. In the CLI, enter the following to disable certain event log messages that you do not want logged:

```
config log disk filter
   set sniffer-traffic disable
   set local-traffic enable
end
```

4. Repeat the steps 2 to 4 for the other FortiGate units.
5. Test the modified settings using the procedure below.

Testing the modified log settings

After modifying both the settings and the FortiGate features for logging, you can test that the modified settings are working properly. This test is done in the CLI.

To test sending logs to the log device

1. In the CLI, enter the following command syntax:

```
diag log test
```

When you enter the command, the following appears:

```
generating a system event message with level - warning
generating an infected virus message with level - warning
generating a blocked virus message with level - warning
generating a URL block message with level - warning
generating a DLP message with level - warning
generating an IPS log message
generating an anomaly log message
generating an application control IM message with level - information
generating an IPv6 application control IM message with level - information
generating deep application control logs with level - information
generating an antispam message with level - notification
generating an allowed traffic message with level - notice
generating a multicast traffic message with level - notice
generating a ipv6 traffic message with level - notice
generating a wanopt traffic log message with level - notification
generating a HA event message with level - warning
```

```
generating netscan log messages with level - notice
generating a VOIP event message with level - information
generating a DNS event message with level - information
generating authentication event messages
generating a Forticlient message with level - information
generating a NAC QUARANTINE message with level - notification
generating a URL block message with level - warning
```

2. In the web-based interface, go to **Log & Report > Event Log > User**, and view the logs to see some of the recently generated test log messages.
   You will be able to tell the test log messages from real log messages because they do not have “real” information; for example, the test log messages for the vulnerability scan contain the destination IP address of 1.1.1.1 or 2.2.2.2.

Configuring the backup solution

Even though you are logging to multiple FortiAnalyzer units, this is more of a redundancy solution rather than a complete backup solution in this example.

The multiple FortiAnalyzer units act similar to a HA cluster, since if one FortiAnalyzer unit fails, the others continue storing the logs they receive. In a backup solution, the logs are backed up to another secure location if something happens to the log device.

A good alternate or redundant option is the FortiCloud service, which can provide secure online logging and management for multiple devices.

Configuring logging to multiple FortiAnalyzer units

The following example shows how to configure logging to multiple FortiAnalyzer units. Configuring multiple FortiAnalyzer units is quick and easy; however, you can only configure up to three FortiAnalyzer units per FortiGate unit.

To configure multiple FortiAnalyzer units

1. In the CLI, enter the following command syntax to configure the first FortiAnalyzer unit:

```
config log fortianalyzer setting
   set status enable
   set server 172.20.120.22
   set max-buffer-size 1000
   set buffer-max-send 2000
   set address-mode static
   set conn-timeout 100
   set monitor-keepalive-period 120
   set monitor-failure-retry-period 2000
end
```

2. Disable the features that you do not want logged, using the following example command syntax. You can view the CLI Reference to see what commands are available.

```
config log fortianalyzer filter
   set traffic (enable | disable)
   ...
end
```

3. Enter the following commands for the second FortiAnalyzer unit:

```
   config log fortianalyzer2 setting
      set status enable
      set server 172.20.120.23
      set max-buffer-size 1000
      set buffer-max-send 2000
      set address-mode static
      set conn-timeout 100
      set monitor-keepalive-period 120
      set monitor-failure-retry-period 2000
end
```

4. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer filter
   set web (enable | disable)
   ...
end
```

5. Enter the following commands for the last FortiAnalyzer unit:

```
   config log fortianalyzer3 setting
      set status enable
      set server 172.20.120.23
      set max-buffer-size 1000
      set buffer-max-send 2000
      set address-mode static
      set conn-timeout 100
      set monitor-keepalive-period 120
      set monitor-failure-retry-period 2000
end
```

6. Disable the features that you do not want logged, using the following example command syntax.

```
config log fortianalyzer filter
   set web-filter (enable | disable)
   ...
end
```

7. Test the configuration by using the procedure, "Testing the modified log settings".
8. On the other FortiGate units, configure steps 1 through 6, ensuring that logs are being sent to the FortiAnalyzer units.

Configuring logging to the FortiCloud server

The FortiCloud server can be used as a redundant backup, or your primary logging solution. The following assumes that this service has already been registered, and a subscription has been purchased for expanded space. The following is an example of how to these settings are configured for a network's log configuration. You need to have access to both the CLI and the web-based manager when configuring uploading of logs. The upload time and interval settings can be configured in the web-based interface.

To configure logging to the FortiCloud server

1. Go to **System > Dashboard > Status** and click **Login** next to **FortiCloud** in the License Information widget.
2. Enter your username and password, and click **OK**. (Or register, if you have not yet done so.)
3. Logs will automatically be uploaded to FortiCloud as long as your FortiGate is linked to your FortiCloud account.
4. To configure the upload time and interval, go to **Log & Report > Log Config > Log Settings**.

5. Under the Logging and Archiving header, you can select your desired upload time.
6. With FortiCloud you can easily store and access FortiGate logs that can give you valuable insight into the health and security of your network.

Modifying the default FortiOS report

The default FortiOS report is provided to help you quickly and easily configure and generate a report. Below is a sample configuration with multiple examples of significant customizations that you can make to tailor reports for larger networks.

Creating datasets

You need to create a new dataset for gathering information about HA, admin activity and configuration changes.

Creating datasets requires SQL knowledge.

To create the datasets

1. Log in to the CLI.
2. Enter the following command syntax:

```
config report dataset
   edit ha
      set query "select subtype_ha count(*) as totalnum from event_log
         where timestamp >= F_TIMESTAMP ('now', 'hour', '-23') and group by subtype_ha
            order by totalnum desc"
      next
```

3. Create a dataset for the admin activity, that includes log ins and log outs from the three FortiGate administrators.

```
      set query "select subtype_admin count(*) as totalnum from event_log
         where timestamp >= F_TIMESTAMP ('now', 'hour', '-23') and group by subtype_
            admin order by totalnum desc"
      next
```

4. Create a dataset for the configuration changes that the administrators did for the past 24 hours.

```
      set query "select subtype_config count(*) as totalnum from event_log
         where timestamp >= F_TIMESTAMP ('now', 'hour', '-23') and group by subtype_
            config order by totalnum desc"
      next
end
```

Creating charts for the datasets

1. Log in to the CLI.
2. Enter the following to create a new chart:

```
config report chart
   edit ha.24h
      set type table
      set period last24h
      set dataset ha
      set category event
      set favorite no
```

```
    set style auto
    set title "24 Hour HA Admin Activity"
end
```

Uploading the corporate images

You need to upload the corporate images so that they appear on the report's pages, as well as on the cover page. Uploading images is only available in the web-based manager.

To upload corporate images

1. Go to **Log & Report > Report > Local**.
2. Select the Image icon and drag it to a place on the page.
3. The Graphic Chooser window appears.
4. Select Upload and then locate the image that you want to upload and upload the image.
   The images are automatically uploaded and saved.
5. Repeat step 4 until the other corporate images are uploaded.
6. Select Cancel to close the Graphic Chooser window and return to the page.

The images can then be placed as you like by reopening the Graphic Chooser as in step 2.

Adding a new report cover and page

You need to add a new cover for the report, as well as a new page that will display the HA activity, admin activity and configuration changes.

To add and customize a new report cover

1. Go to **Log & Report > Report > Local**.
2. Select **Customize**.
3. In **Sections**, select the current default report section, and enter `Report Cover` in the field that appears; then press Enter to save the change.
4. Remove all content from the Report Cover section, and select the image icon and drag it into the main portion of the cover page; select a cover page image and then select **OK**.
5. Select the font size you want, and drag the text icon into the area beneath the image to add a title or explanation for the cover page.
6. Select **Save** to save the new report cover.

To add and customize a new page

1. Go to **Log & Report > Report > Local**.
2. Select **Customize**.
3. Select **Sections**, and select **Create New** to add a new section to the report. Name it `Report Content`, and press **Enter**, and **OK** to close the menu.
4. At the bottom of the editing window is the **Section** selection, where each **Section** is represented by a box. Select the second box.
5. Edit the content for the report as you like.
   For a simpler report structure, make use of the 'FortiGate UTM Security Analysis Report' charts, which automatically format themselves and fill in all necessary information.
   For more complex reports, add headings, default and custom charts, and explanatory text.

6. Select **Save** to save the new report content.
   The report will automatically combine all sections. You can use headers and text to more clearly separate parts of the report, and all properly configured charts have titles built-in.

Advanced logging

This section explains how to configure other log features within your existing log configuration. You may want to include other log features after initially configuring the log topology because the network has either outgrown the initial configuration, or you want to add additional features that will help your network's logging requirements.

The following topics are included in this section:

- Configuring logging to multiple Syslog servers
- Using Automatic Discovery to connect to a FortiAnalyzer unit
- Activating a FortiCloud account for logging purposes
- Viewing log storage space
- Customizing and filtering log messages
- Viewing logs from the CLI
- Configuring NAC quarantine logging
- Logging local-in policies
- Tracking specific search phrases in reports
- Reverting modified report settings to default settings

Configuring logging to multiple Syslog servers

When configuring multiple Syslog servers (or one Syslog server), you can configure reliable delivery of log messages from the Syslog server. Configuring of reliable delivery is available only in the CLI.

If VDOMs are enabled, you can configure multiple FortiAnalyzer units or Syslog servers for each VDOM.

To enable logging to multiple Syslog servers

1. Log in to the CLI.
2. Enter the following commands:

```
config log syslogd setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

3. Enter the following commands to configure the second Syslog server:

```
config log syslogd2 setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

4. Enter the following commands to configure the third Syslog server:

```
config log syslogd3 setting
   set csv {disable | enable}
   set facility <facility_name>
   set port <port_integer>
   set reliable {disable | enable}
   set server <ip_address>
   set status {disable | enable}
end
```

Most FortiGate features are, by default, enabled for logging. You can disable individual FortiGate features you do not want the Syslog server to record, as in this example:

```
config log syslogd filter
   set traffic {enable | disable}
   set web {enable | disable}
   set url-filter {enable | disable}
end
```

Using Automatic Discovery to connect to a FortiAnalyzer unit

Automatic Discovery can be used if the FortiAnalyzer unit is on the same network.

To connect using automatic discovery

1. Log in to the CLI.
2. Enter the following command syntax:

```
config log fortianalyzer setting
   set status enable
   set server <ip_address>
   set gui-display enable
   set address-mode auto-discovery
end
```

If your FortiGate unit is in Transparent mode, the interface using the automatic discovery feature will not carry traffic. For more information about how to enable the interface to also carry traffic when using the automatic discovery feature, see the Fortinet Knowledge Base article, Fortinet Discovery Protocol in Transparent mode.

The FortiGate unit searches within the same subnet for a response from any available FortiAnalyzer units.

Activating a FortiCloud account for logging purposes

When you subscribe to FortiCloud, you can configure to send logs to the FortiCloud server. The account activation can be done within the web-based manager, from the **License Information** widget located in **System > Dashboard**.

From this widget, you can easily create a new account, or log in to the existing account. From within the License Information widget, after the account is activated, you can go directly to the FortiCloud web portal, or log out of the service if you are already logged in.

To activate a FortiCloud account for logging purposes:

The following assumes that you are already at **System > Dashboard** and that you have located the License Information widget.

1. In the License Information widget, select **Activate** in the **FortiCloud** section.
   The Registration window appears. From this window, you create the login credentials that you will use to access the account.
2. Select **Create Account** and enter then information for the login credentials.
   After entering the login credentials, you are automatically logged in to your FortiCloud account.
3. Check that the account has been activated by viewing the account status from the License Information widget.

If you need more space, you can subscribe to the 200Gb FortiCloud service by selecting **Upgrade** in the **FortiCloud** section of the widget.

Viewing log storage space

The `diag sys logdisk usage` command allows you to view detailed information about how much space is currently being used for logs. This is useful when you see a high percentage, such as 92 percent for the disk's capacity. The FortiGate unit uses only 75 percent of the available disk capacity to avoid a high storage amount so when there is a high percentage, it refers to the percentage of the 75 percent that is available. For example, 92 percent of the 75 percent is available.

The following is an example of what you may see when you use `diag sys logdisk usage` command on a unit with no VDOMs configured:

```
diag sys logdisk usage
```

The following appears:

```
Total HD usage: 176MB/3011 MB
Total HD logging space: 22583MB
Total HD logging space for each vdom: 22583MB
HD logging space usage for vdom "root": 30MB/22583MB
```

Customizing and filtering log messages

When viewing log messages, you may want to customize and filter the information that you are seeing in the Log & Report menu (for example, Log & Report > Traffic Log > Forward Traffic). Filtering and customizing the display provides a way to view specific log information without scrolling through pages of log messages to find the information.

Customizing log messages is the process of removing or adding columns to the log display page, allowing you to view certain desired information. The most columns represent the fields from within a log message, for example, the user column represents the user field, as well as additional information. If you want to reset the customized columns on the page back to their defaults, you need to select **Reset All Columns** within the column title right-click menu.

Filtering information is similar to customizing, however, filtering allows you to enter specific information that indicates what should appear on the page. For example, including only log messages that appeared on February 24, between the hours of 8:00 and 8:30 am.

To customize and filter log messages

The following is an example that displays all traffic log messages that originate from the source IP address 172.20.120.24, as well as displaying only the columns:

- OS Name
- OS Version
- Policy ID
- Src (Source IP)

The following assumes that you are already on the page of the log messages you want to customize and filter. In this example, the log messages that we are customizing and filtering are in **Log & Report > Traffic Log > Forward Traffic**.

1. On the Forward Traffic page, right click anywhere on a column title.
2. Right click on a column title, and mouse over **Column Settings** to open the list.
3. Select each checkmarked title to uncheck it and remove them all from the displayed columns.
4. Scroll down to the list of unchecked fields and select 'OS Name', 'OS Version', 'Policy ID', and 'Src' to add checkmarks next to them.
5. Click outside the menu, and wait for the page to refresh with the new settings in place.
6. Select the funnel icon next to the word Src in the title bar of the Src column.
7. Enter the IP you want displayed (in this example, 172.20.120.24) in the text box.
8. Click **Apply**, and wait for the page to reload.

Viewing logs from the CLI

You can easily view log messages from within the CLI. In this example, we are viewing DLP log messages.

1. Log in to the CLI and then enter the following to configure the display of the DLP log messages.

   ```
   execute log filter category 9
   execute log filter start-line 1
   execute log filter view-lines 20
   ```

   The customized display of log messages in the CLI is similar to how you customize the display of log messages in the web-based manager. For example, `category 9` is the DLP log messages, and the `start-line` is the first line in the log database table for DLP log messages, and there will be 20 lines (`view-lines 20`) that will display.

2. Enter the following to view the log messages:

   ```
   execute log display
   ```

   The following appears below execute log display:

   ```
   600 logs found
   20 logs returned
   ```

   along with the 20 DLP log messages.

Configuring NAC quarantine logging

NAC quarantine log messages provide information about what was banned and quarantined by a Antivirus profile. The following explains how to configure NAC quarantine logging and enable it on a policy. This procedure assumes the Antivirus profile is already in place.

To configure NAC quarantine logging

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select the policy that you want to apply the Antivirus profile to, and then select **Edit**.
3. Within the Security Profiles section, enable **Antivirus** and then select the profile from the drop-down list.
4. Select **OK**.
5. Log in to the CLI.
6. Enter the following to enable NAC quarantine in the DLP sensor:

```
config antivirus profile
   edit <profile_name>
      config nac-quar log enable
   end
```

Logging local-in policies

Local-in security policies are policies the control the flow of internal traffic, and can be used to broaden or restrict an administrator's access privileges. These local-in policies can also be configured to log traffic and activity that the policies control.

You can enable logging of local-in policies in the CLI, with the following commands:

```
config system global
   set gui-local-in-policy enable
end
```

The Local-In Policy page will then be available in **Policy & Objects > Policy > Local In**. You can configure what local-in traffic to log in the CLI, or in **Log & Report > Log Config > Log Settings**, under **Local Traffic Logging**.

When deciding what local-in policy traffic you want logged, consider the following:

Special Traffic

Traffic activity	Traffic Direction	Description
FortiGuard update annouce-ments	IN	All push announcements of updates that are coming from the FortiGuard system. For example, IPS or AV updates.
FortiGuard update requests	OUT	All updates that are checking for antivirus or IPS as well as other FortiGuard service updates.
Firewall authen-tication	IN	The authentication made using either the web-based manager or CLI.
Central man-agement (a FortiGate unit being managed by a FortiMan-ager unit)	IN	The access that a FortiManager has managing the FortiGate unit.
DNS	IN	All DNS traffic.
DHCP/DHCP Relay	IN	All DHCP and/or DHCP Relay traffic.
HA (heart beat sync policy)	IN/OUT	For high-end platforms with a backplane heart beat port.
HA (Session sync policy)	IN/OUT	This will get information from the CMDB and updated by session sync daemon.
CAPWAP	IN	This activity is logged only when a HAVE_CAPWAP is defined.
Radius	IN	This is recorded only within FortiCarrier.
NETBIOS forward	IN	Any interface that NETBIOS forward is enabled on.
RIP	IN	
OSPF	IN	
VRRP	IN	
BFD	IN	
IGMP	IN	This is recorded only when PIM is enabled.
PIM	IN	This is recorded only when PIM is enabled.
BGP	IN	This is recorded only when config bgp and bgp neightbor is enabled in the CLI.

Traffic activity	Traffic Direction	Description
WCCP policy	IN	Any interface that WCCP is enabled; however, if in Cache mode, this is not recorded because it is not available.
WAN Opt/ Web Cache	IN	Any interface where WAN Opt is enabled.
WANOpt Tunnel	IN	This is recorded when HAVE_WANOPT is defined.
SSL-VPN	IN	Any interface from a zone where the action in the policy is SSL VPN.
IPSEC	IN	
L2TP	IN	
PPTP	IN	
VPD	IN	This is recorded only when FortiClient is enabled.
Web cache db test facility	IN	This is recorded only when WA_CS_REMOTE_TEST is defined.
GDBserver	IN	This is recorded only when debug is enabled.

Tracking specific search phrases in reports

It is possible to use the Web Filter to track specific search keywords and phrases and record the results for display in the report.

You should verify that the web filter profile you are using indicates what search phrases you want to track and monitor, so that the report includes this information.

1. **Log in to the CLI and enter show webfilter profile default.**
   This provides details about the webfilter profile being used by the security policy. In this example, the details (shown in the following in bold) indicate that safe search is enabled, but not specified or being logged.

```
show webfilter profile default
   config webfilter profile
      edit "default"
         set comment "default web filtering"
         set inspection-mode flow-based
         set options https-scan
         set post-action comfort
            config web
               set safe-search url
            end
            config ftgd-wf
               config filters
                  edit 1
                     set action block
                     set category 2
                  next
```

```
edit 2
   set action block
   set category 7
next
edit 3
   set action block
   set category 8
```

2. **Enter the following command syntax so that logging and the keyword for the safe search will be included in logging.**

```
config webfilter profile
   edit default
      config web
         set log-search enable
         set keyword-match "fortinet" "easter" "easter bunny"
      end
   end
```

3. **To test that the keyword search is working, go to a web browser and begin searching for the words that were included in the webfilter profile, such as easter.**
   You can tell that the test works by going to **Log & Report > Traffic Log > Forward Traffic** and viewing the log messages.

Reverting modified report settings to default settings

If you need to go back to the original default report settings, you can easily revert to those settings in the Report menu. Reverting to default settings means that your previously modified report settings will be lost.

To revert back to default report settings, in **Log & Report > Report > Local**, select **Customize**, and then **Restore Defaults** from the top navigation. This may take a minute or two. You can also use the CLI command `execute report-config reset` to reset the report to defaults.

If you are having problems with report content being outdated or incorrect, especially after a firmware update, you can recreate the report database using your current log information with the CLI command `execute report recreate-db`.

Troubleshooting and logging

This section explains how to troubleshoot logging configuration issues, as well as connection issues, that you may have with your FortiGate unit and a log device. This section also contains information about how to use log messages when troubleshooting issues that are about other FortiGate features, such as VPN tunnel errors.

Using log messages to help in troubleshooting issues

Log messages can help when troubleshooting issues that occur, since they can provide details about what is occurring. The uses and methods for involving logging in troubleshooting vary depending on the problem. The following are examples of how log messages can assist when troubleshooting networking issues.

Using IPS packet logging in diagnostics

This type of logging should only be enabled when you need to know about specific diagnostic information, for example, when you suspect a signature is triggered by a false positive. These log messages can help troubleshoot individual problems with misidentified or missing packets and network intrusions involving malicious packets.

To configure IPS packet logging

1. Go to **Security Profiles > Intrusion Protection**.
2. Select the IPS sensor that you want to enable IPS packet logging on, and then select **Edit**.
3. In the filter options, enable **Packet Logging**.
4. Select **OK**.

If you want to configure the packet quota, number of packets that are recorded before alerts and after attacks, use the following procedure.

To configure additional settings for IPS packet logging

1. Log in to the CLI.
2. Enter the following to start configuring additional settings:

```
config ips settings
     set ips-packet-quota <integer>
     set packet-log-history <integer>
     set packet-log-post-attack <integer>
end
```

Using HA log messages to determine system status

When the FortiGate unit is in HA mode, you may see the following log message content within the event log:

```
type=event subtype=ha level=critical msg= "HA slave heartbeat interface internal lost
    neighbor information"
```

OR

```
type=event subtype=ha level=critical msg= "Virtual cluster 1 of group 0 detected new
    joined HA member"
```

OR

```
type=event subtype=ha level=critical msg= "HA master heartbeat interface internal get peer
    information"
```

The log messages occur within a given time, and indicate that the units within the cluster are not aware of each other anymore. These log messages provide the information you need to fix the problem.

Connection issues between FortiGate unit and logging devices

If external logging devices are not recording the log information properly or at all, the problem will likely be due to one of two situations: no data is being received because the log device cannot be reached, or no data is being sent because the FortiGate unit is no longer logging properly.

Unable to connect to a supported log device

After configuring logging to a supported log device, and testing the connection, you may find you cannot connect. To determine whether this is the problem:

1. Verify that the information you entered is correct; it could be a simple mistake within the IP address or you may have not selected **Apply** on the Log Settings page after changing them, which would prevent them from taking effect.
2. Use `execute ping` to see if you can ping to the log device.
3. If you are unable to ping to the log device, check to see if the log device itself working and that it is on the network and assigned an appropriate address.

FortiGate unit has stopped logging

If the FortiGate unit stopped logging to a device, test the connection between both the FortiGate unit and device using the execute ping command. The log device may have been turned off, is upgrading to a new firmware version, or just not working properly.

The FortiGate unit may also have a corrupted log database. When you log into the web-based manager and you see an SQL database error message, it is because the SQL database has become corrupted. View "SQL database errors" in the next section before taking any further actions, to avoid losing your current logs.

Log database issues

If attempting to troubleshoot issues with the SQL log database, use the following to help guide you to solving issues that occur.

SQL statement syntax errors

There may be errors or inconsistencies in the SQL used to maintain the database. Here are some example error messages and possible causes:

```
You have an error in your SQL syntax (remote/MySQL)
```

or

```
ERROR: syntax error at or near... (local/PostgreSQL)
```

- Verify that the SQL keywords are spelled correctly, and that the query is well-formed.
- Table and column names are demarked by grave accent (`) characters. Single (') and double (") quotation marks will cause an error.

```
No data is covered.
```

- The query is correctly formed, but no data has been logged for the log type. Verify that you have configured the FortiGate unit to save that log type. On the Log Settings page, make sure that the log type is checked.

Connection problems

If well-formed SQL queries do not produce results, and logging is turned on for the log type, there may be a database configuration problem with the remote database.

Ensure that:

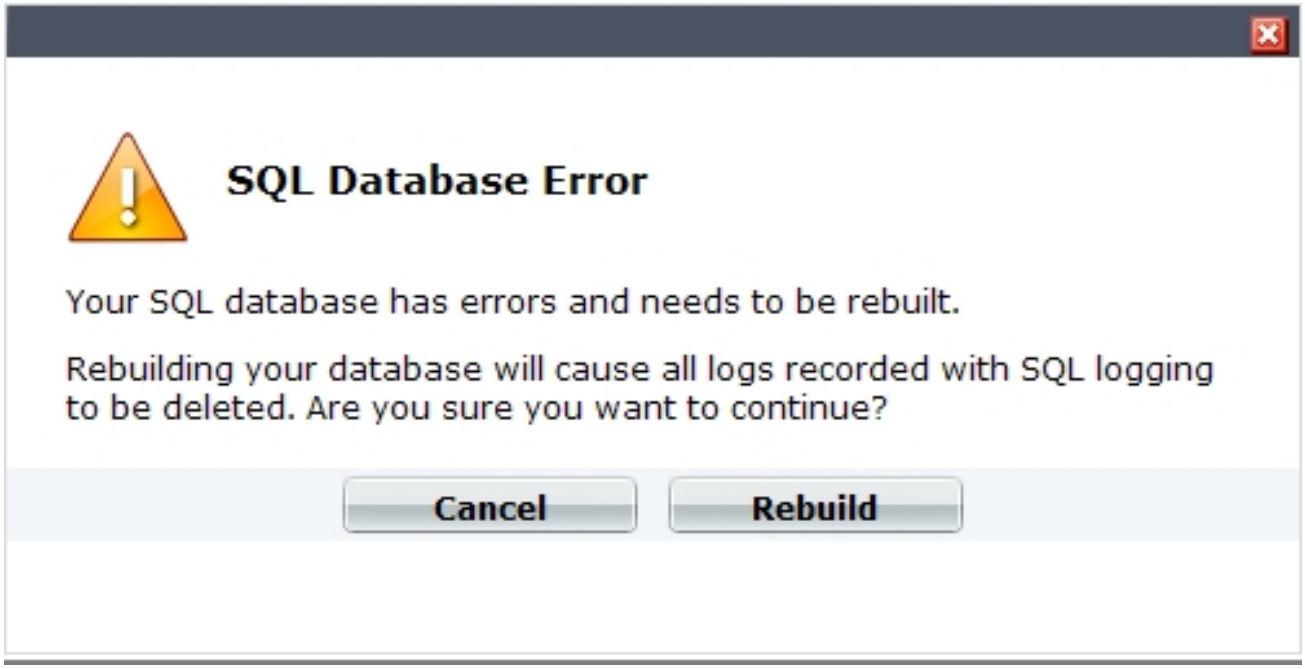
- MySQL is running and using the default port 3306.
- You have created an empty database and a user who has read/write permissions for the database.
- Here is an example of creating a new MySQL database named fazlogs, and adding a user for the database:

1. `#Mysql -u root -p`
2. `mysql>` Create database fazlogs;
3. `mysql>` Grant all privileges on fazlogs.* to 'fazlogger'@'*' identified by 'fazpassword';
4. `mysql>` Grant all privileges on fazlogs.* to 'fazlogger'@'localhost' identified by 'fazpassword';

SQL database errors

If the database seems inacessible, you may encounter the following error message after upgrading or downgrading the FortiGate unit's firmware image.

Example of an SQL database error message



The error message indicates that the SQL database is corrupted and cannot be updated with the SQL schemas any more. When you see this error message, you can do one of the following:

- select **Cancel** and back up all log files; then select **Rebuild** to blank and rebuild the database.
- select **Rebuild** immediately, which will blank the database and previous logs will be lost.

Until the database is rebuilt, no information will be logged by the FortiGate unit regardless of the log settings that are configured on the unit. When you select **Rebuild**, all logs are lost because the SQL database is erased and then rebuilt again. Logging resumes automatically according to your settings after the SQL database is rebuilt.

To view the status of the database, use the `diagnose debug sqldb-error status` command in the CLI. This command will inform you whether the database has errors present.

If you want to view the database's errors, use the `diagnose debug sqldb-error read` command in the CLI. This command indicates exactly what errors occurred, and what tables contain those errors.

Log files are backed up using the `execute backup {disk | memory } {alllogs | logs}` command in the CLI. You must use the text variable when backing up log files because the text variable allows you to view the log files outside the FortiGate unit. When you back up log files, you are really just copying the log files from the database to a specified location, such as a TFTP server.

Logging daemon (Miglogd)

The number of logging daemon child processes has been made available for editing. A higher number can affect performance, and a lower number can affect log processing time, although no logs will be dropped or lost if the number is decreased.

If you are suffering from performance issues, you can alter the number of logging daemon child processes, from 0 to 15, using the following syntax. The default is 8.

```
config system global
   set miglogd-children <integer>
end
```

Chapter 19 - Managing Devices

This handbook chapter contains the following sections:

Managing “bring your own device” describes device monitoring, devices, device groups, and device policies. The administrator can monitor all types of devices and control their access to network resources.

Endpoint Protection describes how you can enforce the use of FortiClient Endpoint Control and apply an endpoint profile to users’ devices. Endpoint profiles include real-time antivirus protection, application control, web category filtering, and VPN provisioning.

Vulnerability Scan describes how perform network vulnerability scanning to look for security weaknesses in your servers and workstations.

Managing “bring your own device”

FortiOS can control network access for different types of personal mobile devices that your employees bring onto your premises. You can:

- identify and monitor the types of devices connecting to your networks, wireless or wired
- use MAC address based access control to allow or deny individual devices
- create security policies that specify device types
- enforce endpoint control on devices that can run FortiClient Endpoint Control software

Device monitoring

The FortiGate unit can monitor your networks and gather information about the devices operating on those networks. Collected information includes:

- MAC address
- IP address
- operating system
- hostname
- user name
- how long ago the device was detected and on which FortiGate interface

You can go to **User & Device > Device > Device Definitions** to view this information. Mouse-over the **Device** column for more details.

Device monitoring is enabled separately on each interface. Device detection is intended for devices directly connected to your LAN ports. If enabled on a WAN port, device detection may be unable to determine the operating system on some devices.

To configure device monitoring

1. Go to **System > Network > Interfaces**.
2. Edit the interface that you want to monitor devices on.
3. In **Device Management**, select **Detect and Identify Devices**.
4. Select **OK**.
5. Repeat steps 2 through 4 for each interface that will monitor devices.

For ease in identifying devices, Fortinet recommends that you assign each device an Alias.

To assign an alias to a detected device or change device information

1. Go to **User & Device > Device > Device Definitions.**
2. Double-click the device entry or right-click it and select **Edit**.
3. Enter an **Alias** such as the user’s name to identify the device.
   This is step is compulsory. The alias replaces the MAC address in the device list.
4. Change other information as needed.
5. Select **OK**.

To add a device manually

1. Go to **User & Device > Device > Device Definitions** and select **Create New**.
2. Enter the following information:
   - Alias (required)
   - MAC address
   - Device Type
   - Optionally, add the device to **Custom Groups**.
   - Optionally, enter **Comments**.
3. Select **OK**.

Device Groups

You can specify multiple device types in a security policy. As an alternative, you can add multiple device types to a custom device group and include the group in the policy. This enables you to create a different policy for devices that you know than for devices in general.

To create a custom device group and add devices to it

1. Go to **User & Device > Device > Device Groups.**
   The list of device groups is displayed.
2. Select **Create New**.
3. Enter a **Name** for the new device group.
4. Click in the **Members** field and click a device type to add. Repeat to add other devices.
5. Select **OK**.

Controlling access with a MAC Address Access Control List

A MAC Address Access Control List (ACL) allows or blocks access on a network interface that includes a DHCP server. If the interface does not use DHCP, or if you want to limit network access to a larger group such as employee devices, it is better to create a device group and specify that group in your security policies.

A MAC Address ACL functions as either a list of blocked devices or a list of allowed devices. This is determined by the **Unknown MAC Address** entry.

By default, the ACL is a list of blocked devices. The **Unknown MAC Address** entry **Action** is **Assign IP**. You add an entry for each MAC address that you want to block and set its **Action** to **Block**.

If you want the ACL to allow only a limited set of devices, you set the **Unknown MAC Address** entry to **Bloc**. Then, add the MAC address of each allowed device. Set **Action** to **Assign IP**. Optionally, you can set **Action** to **Reserve** and enter the IP address that will always be assigned to the device.

To create a MAC Address ACL to allow only specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
   DHCP Server must be enabled.
3. In **MAC Reservation + Access Control,** select **Create New** and enter an allowed device’s **MAC Address**.
4. In the **IP or Action** column, select one of:
   - Assign IP — device is assigned an IP address from the DHCP server address range.
   - Reserve IP — device is assigned the IP address that you specify.
5. Repeat Steps "Managing “bring your own device”" on page 1946 and "Managing “bring your own device”" on page 1946 for each additional MAC address entry.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Block**.
7. Select **OK**.

To create a MAC Address ACL to block specific devices

1. Go to the SSID or network interface configuration.
2. In the **DHCP Server** section, expand **Advanced**.
   DHCP Server must be enabled.
3. In **MAC Reservation + Access Control,** select **Create New** and enter a blocked device’s **MAC Address**.
4. In the **IP or Action** column, select **Block**.
5. Repeat Steps "Managing “bring your own device”" on page 1946 and "Managing “bring your own device”" on page 1946 for each additional MAC address entry.
6. Set the **Unknown MAC Address** entry **IP or Action** to **Assign IP**.
7. Select **OK**.

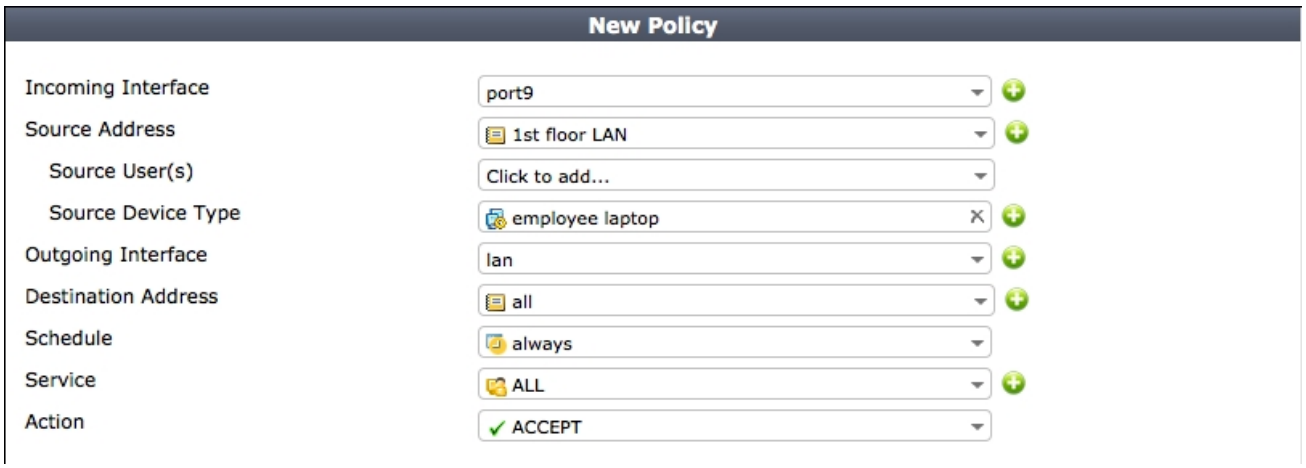
Security policies for devices

Security policies enable you to implement policies according to device type. For example:

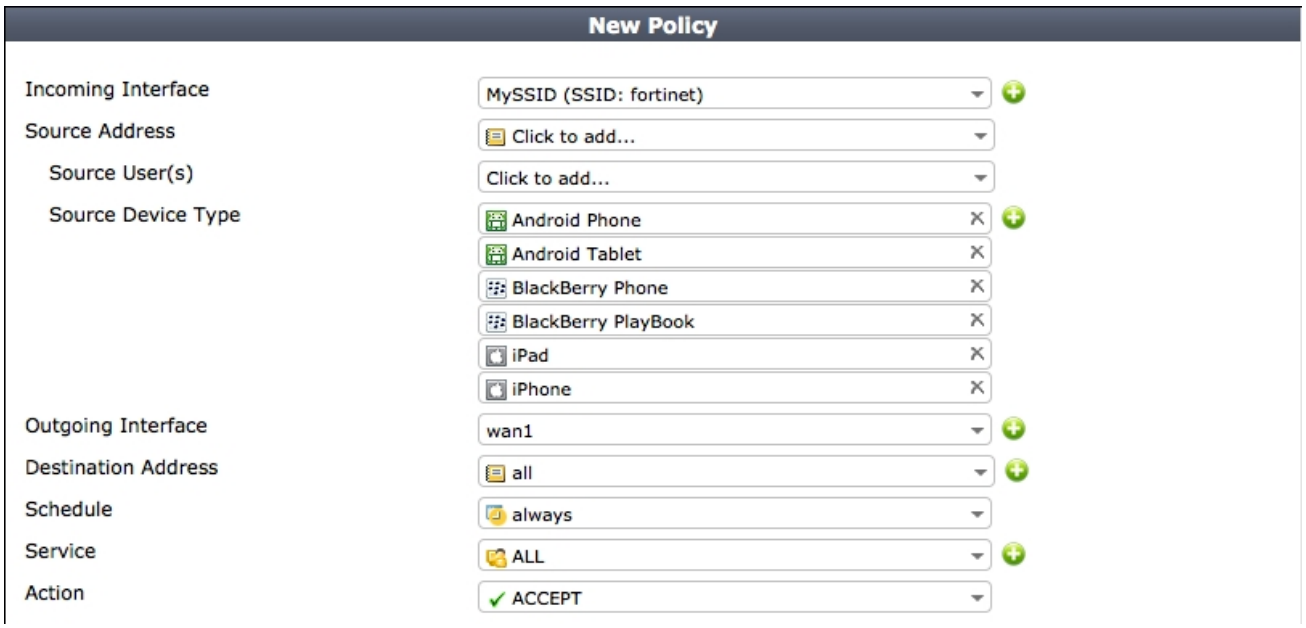
- Gaming consoles cannot connect to the company network or the Internet.
- Personal tablet and phone devices can connect to the Internet but not to company servers.
- Company-issued laptop computers can connect to the Internet and company servers. Web filtering and antivirus are applied.
- Employee laptop computers can connect to the Internet, but web filtering is applied. They can also connect to company networks, but only if FortiClient Endpoint Security is installed to protect against viruses.

The following images show these policies implemented for WiFi to the company network and to the Internet.

Device policies for company laptop access to the company network



Device policies for WiFi access to the Internet



The next section explains device policy creation in detail.

Creating device policies

Device-based security policies are similar to policies based on user identity:

- The policy enables traffic to flow from one network interface to another.
- NAT can be enabled.
- UTM protection can be applied.

To create a device policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Choose **Incoming Interface**, **Source Address**, and **Outgoing Interface** as you would for any security policy.
3. In Source Device Type, select the device types that can use this policy.
   You can select multiple devices or device groups.
4. Select **Enable NAT** if appropriate.
5. Configure **UTM Security Profiles** as you would for any security policy.
6. Select **OK**.

Adding endpoint protection

Optionally, you can require that users’ devices have FortiClient Endpoint Security software installed. FortiOS pushes a FortiClient profile out to the FortiClient software, configuring network protection such as antivirus, application control, and web category filtering. Devices without an up-to-date installation of FortiClient software are restricted to a captive portal from which the user can download a FortiClient installer. For information about creating FortiClient profiles, see "Endpoint Protection".

To add endpoint protection to a security policy

1. Go to **Policy & Objects > Policy > IPv4** and edit the policy.
2. In **Firewall / Network Options** set **Compliant with FortiClient Profile** to **ON**.
   The policy must have device types or gevice groups in the **Source Device Type** field.

Endpoint Protection

This section describes the Endpoint Protection feature and how to configure it.

The following topics are included in this section:

- Endpoint Protection overview
- Configuration overview
- Creating a FortiClient profile
- Enabling Endpoint Protection in security policies
- Configuring endpoint registration over a VPN
- Monitoring endpoints
- Modifying the Endpoint Protection replacement messages

Endpoint Protection overview

Endpoint Protection enforces the use of up-to-date FortiClient Endpoint Security software on endpoints (workstation computers and mobile devices). It pushes a FortiClient profile to the FortiClient application, specifying security settings, including:

- Real-time antivirus protection - on or off
- FortiClient web category filtering based on web filters defined in a FortiGate web filter profile
- FortiClient application control (application firewall) using application sensors defined in the FortiGate application control feature

The FortiClient profile can also specify:

- VPN configurations
- Configuration profile (.mobileconfig file for iOS)
- Dashboard banner

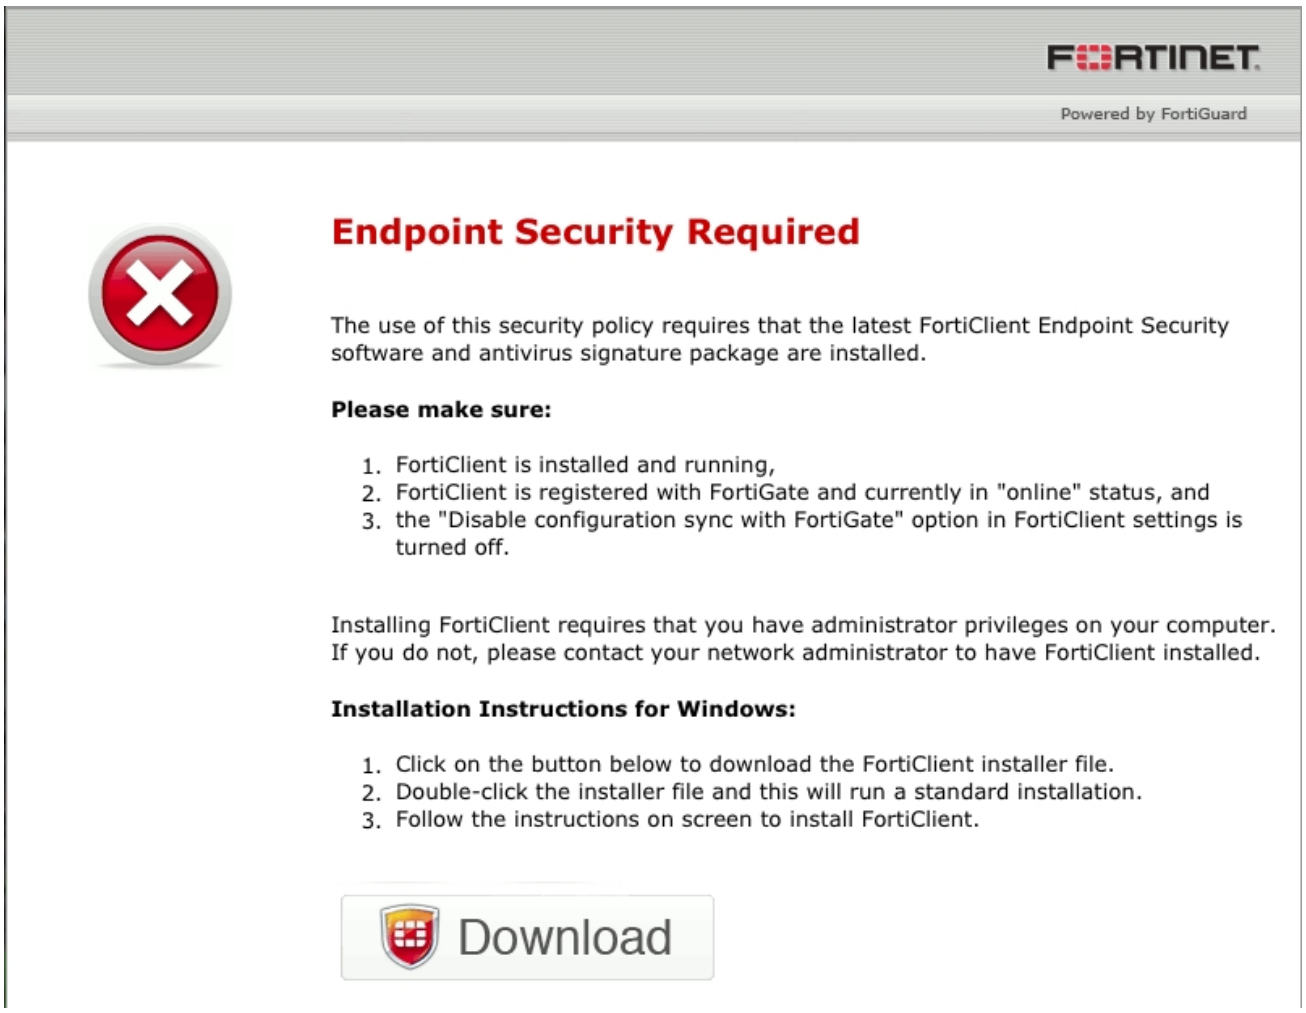
You enable Endpoint Security in security policies by enabling **Compliant with FortiClient Profile**. The policy must specify at least one device type.

User experience

When using a web browser, the user of a non-compliant endpoint receives a replacement message HTML page from the FortiGate unit. The message explains that the user needs to install FortiClient Endpoint Security and provides a link to do so. The user cannot continue until the FortiClient software is installed.

For information about modifying the replacement page, see Modifying the Endpoint Protection replacement messages on page 1958.

Default FortiClient non-compliance message for Windows



After installing FortiClient Endpoint Security, the user will receive an invitation to register with the FortiGate unit. If the user accepts the invitation, the FortiClient profile is sent to the device's FortiClient application. Now the user is compliant with the security policy and can connect to the network. FortiClient Endpoint Security registered with a FortiGate unit does not need to be separately licensed with FortiGuard.

The FortiGate unit can also register endpoints who connect over the Internet through a VPN. The user can accept an invitation to register with the FortiGate unit. See Configuring endpoint registration over a VPN on page 1957.

FortiGate endpoint registration limits

To view the number of endpoints that are registered and the total that can be registered, go to **System > Dashboard > Status**. Under **License Information**, find **FortiClient**. You will see a line like “Registered/Allowed 4 of 10”. This means that there are four registered endpoints and a total of ten are allowed.

When the registration limit is reached, the next FortiClient-compatible device will not be able to register with the FortiGate unit. The user sees a message in FortiClient application about this. The FortiClient profile is not sent to client and the client cannot connect through the FortiGate unit.

For all FortiGate models, the maximum number of registered endpoints is ten. For all models except 20C, you can purchase an endpoint license to increase this capacity:

To add an endpoint license - web-based manager

1. Go to **System > Dashboard > Status**.
2. In the **License Information** widget, under **FortiClient**, select **Enter License**, enter the license key, and select **OK**.

Maximum registered endpoints with endpoint license

Model type	Max Registered Endpoints
30 to 90 series	200
100 to 300 series	600
500 to 800 series, VM1, VM2	2 000
1000 series, VM4	8 000
3000 to 5000 series, VM8	20 000

Configuration overview

Endpoint Protection requires that all hosts using the firewall policy have the FortiClient Endpoint Security application installed. Make sure that all hosts affected by this policy are able to install this application. Currently, FortiClient Endpoint Security is available for Microsoft Windows (2000 and later) and Apple Mac OSX only.

To set up Endpoint Protection, you need to:

- By default, the FortiGuard service provides the FortiClient installer. If you prefer to host it on your own server, see Changing the FortiClient installer download location, below.
- In Security Profiles, configure application sensors and web filter profiles as needed to monitor or block applications. See the Security Profiles Guide for details.
- Create a FortiClient profile or use the default profile. See Creating a FortiClient profile on page 1954. Enable the application sensor and web category filtering profiles that you want to use.
- Enable **Compliant with FortiClient Profile** in the security policies that the endpoints will use.
- Create the registration key for users to register their device with the FortiGate unit.
- Optionally, configure the FortiGate unit to support endpoint registration by IPsec or SSL VPN.
- Optionally, modify the **Endpoint NAC Download Portal** replacement messages (one per platform).

Changing the FortiClient installer download location

By default, FortiClient installers are downloaded from the FortiGuard network. You can also host these installers on a server for your users to download. In that case, you must configure FortiOS with this custom download

location. For example, to set the download location to a customer web server with address custom.example.com, enter the following command:

```
config endpoint-control settings
   set download-location custom
   set download-custom-link "http://custom.example.com"
end
```

Creating a FortiClient profile

There is a default FortiClient profile for Windows and Mac OS that enables only AntiVirus, Web Filtering, and VPN. You can modify this profile or create your own FortiClient profiles.

Except for the default profile, each FortiClient profile is assigned to particular device groups, and optionally to particular users and user groups. If no other FortiClient profile is assigned to a particular device type, the default profile applies. It is possible for more than one profile to be assigned to a device type. As with security policies, clients are matched to FortiClient profiles in the order that the profiles appear in the list.

When **Compliant with FortiClient Profile** is selected in the security policy, all users of that policy must have FortiClient Endpoint Security installed. The FortiGate unit pushes the FortiClient profile settings to the FortiClient application on the client.

To create a FortiClient profile - web-based manager

1. If you will use the Application Firewall feature, go to **Security Profiles > Application Control** to create the Application Sensors that you will need.
2. If you will use Web Category Filtering, go to **Security Profiles > Web Filter** to create the web filter profile that you will need.
3. Go to **User & Device > FortiClient Profiles**.
   If there is only the default FortiClient profile, it is displayed, ready to edit. At the top right of the page you can select or create other profiles.
4. Select **Create New** or select an existing profile and **Edit** it.
5. In **Assign Profile To**, select the device groups, user groups, and users to which this FortiClient profile applies. This is not available for the default profile.
6. Enter the **FortiClient Configuration Deployment** settings for **Windows and Mac**:

Antivirus Protection	ON — enable the FortiClient realtime AntiVirus feature.
Web Category Filtering	ON — enable web category filtering. Select the web filter profile to use.
Client Web Filtering when On-Net	Enable to use FortiClient web filtering.
VPN	ON - enable VPN use by FortiClient.
Client VPN Provisioning	Enable to configure the FortiClient VPN client. Enter the VPN configuration details.
Application Firewall	ON — enable application control. Select the application sensor to use.

Upload Logs to FortiAnalyzer / FortiManager	ON — enable log upload. Specify log device and select schedule.
Use FortiManager for client software/signature update	ON — FortiClient software obtain AV signatures and software updates from the specified FQDN or IP address. **Failover to FDN when FortiManager is not available** is enabled by default.
Dashboard Banner	ON — Display dashboard banner.
Client-based Logging when On-Net	ON — FortiClient will continue to log even when its traffic is flowing through a FortiGate unit.

7. Enter the **FortiClient Configuration Deployment** settings for **iOS**:

Web Category Filtering	ON — enable web category filtering. Select the web filter profile to use.
Client Web Filtering when On-Net	Enable to use FortiClient web filtering.
Client VPN Provisioning	Enable to configure the FortiClient VPN client. You can enter multiple VPN configurations by selecting the “+” button.
VPN Name	Enter a name to identify this VPN configuration in the FortiClient application.
Type	Select **IPsec** or **SSL-VPN**. If you select **IPsec**, select a **VPN Configuration File** that contains the required IPsec VPN configuration. The Apple iPhone Configuration Utility produces .mobileconfig files which contain configuration information for an iOS device. If you select **SSL-VPN**, enter the VPN configuration details.
Distribute Configuration Profile	ON — Distribute configuration information to iOS devices running FortiClient Endpoint Security. Select **Browse** and locate the file to be distributed. The Apple iPhone Configuration Utility produces .mobileconfig files which contain configuration information for an iOS device.

8. Enter the **FortiClient Configuration Deployment** settings for **Android**:

Web Category Filtering	ON — enable web category filtering. Select the web filter profile to use.
Client Filtering when On-Net	Disables FortiClient web category filtering when client traffic is filtered by the FortiGate unit. Selected by default.
Client VPN Provisioning	Enable to configure the FortiClient VPN client. You can enter multiple VPN configurations by selecting the “+” button.

VPN Name	Enter a name to identify this VPN configuration in the FortiClient application.
Type	Select **IPsec** or **SSL-VPN**. Enter the VPN configuration details.

9. Select **OK**.

To create a FortiClient profile - CLI:

This example creates a profile for Windows and Mac computers.

```
config endpoint-control profile
   edit ep-profile1
      set device-groups mac windows-pc
      config forticlient-winmac-settings
         set forticlient-av enable
         set forticlient-wf enable
         set forticlient-wf-profile default
      end
   end
```

Creating the registration key

To register their endpoint devices with the FortiGate unit, users must enter a registration key that you create and provide to them.

To create the FortiClient Endpoint Registration key

1. Go to **System > Config > Advanced**.
2. Enable **FortiClient Endpoint Registration** and enter the key.
   You can create a key containing up to 127 alphanumeric characters.
3. Select **Apply**.

Enabling Endpoint Protection in security policies

Endpoint Protection is applied to any traffic where the controlling firewall policy has Endpoint Security enabled. The device group to which the device belongs determines which FortiClient profile is applied. The policy searches the list of FortiClient profiles starting from the top and applies the first profile assigned to the device group.

To enable Endpoint Protection - web-based manager:

1. Go to **Policy & Objects > Policy > IPv4** and edit the security policy where you want to enable Endpoint Protection.
   The policy must specify at least one **Source Device Type**.
2. Select **Compliant with FortiClient profile**.
3. Select **OK**.

To configure the firewall policy - CLI:

In this example, the LAN connects to Port 2 and the Internet is connected to Port 1. a FortiClient profile is applied.

```
config firewall policy
   edit 0
      set srcintf port2
      set dstintf port1
      set srcaddr LANusers
      set dstaddr all
      set devices employee\ laptop
      set schedule always
      set service ALL
      set devices all
      set action accept
      set nat enable
      set endpoint-compliance enable
   end
```

Configuring endpoint registration over a VPN

FortiGate units can register FortiClient-equipped endpoints over either an interface-based IPsec VPN or a tunnel-mode SSL VPN. After the user authenticates, the FortiGate unit sends the FortiClient application the IP address and port to be used for registration. If the user accepts the FortiGate invitation to register, registration proceeds and the FortiClient profile is downloaded to the client.

Users without FortiClient Endpoint Security connecting to the SSL VPN through a browser are redirected to a captive portal to download and install the FortiClient software.

Endpoint registration on an IPsec VPN

You can enable endpoint registration when you configure the FortiClient VPN or you can enable it on an existing FortiClient VPN.

To enable endpoint registration while configuring the VPN

- Enable **Allow Endpoint Registration** on the Policy & Routing page of the VPN Wizard when creating the FortiClient VPN.

To enable endpoint registration on an existing VPN

1. Go to **System > Network > Interfaces** and edit the VPN's tunnel interface.
   The tunnel is a subinterface of the physical network interface.
2. In **Administrative Access**, make sure that **FCT-Access** is enabled.
3. Select **OK**.

Endpoint registration on an SSL VPN

To enable endpoint registration on the SSL VPN

1. Go to **VPN > SSL > Settings.**
2. In **Tunnel Mode Client Settings**, make sure **Allow Endpoint Registration** is enabled.

3. Select **Apply**.

This procedure does not include all settings needed to configure a working SSL VPN.

Synchronizing endpoint registrations

To support roaming users in a network with multiple FortiGate units, you need to configure synchronization of the endpoint registration databases between the units. The registered endpoints are then recognized on all of the FortiGate units. This is configured in the CLI. For example, to synchronize this FortiGate unit's registered endpoint database with another unit named `other1` at IP address 172.20.120.4, enter:

```
config endpoint-control forticlient-registration-sync
   edit other1
      set peer-ip 172.20.120.4
   end
```

Monitoring endpoints

Go to **User & Device > Monitor > FortiClient** to monitor endpoints.

Modifying the Endpoint Protection replacement messages

If the security policy has **Redirect all non-compliant/unregistered FortiClient compatible devices to a captive portal** enabled, users of non-compliant devices are redirected to a captive portal that is defined by the **Endpoint NAC Download Portal** replacement message. There are different portals for Android, iOS, Mac, Windows, and "other" devices. Optionally, you can modify them.

To modify the Endpoint NAC Download Portal

1. Go to **System > Config > Replacement Message Group** and select **Extended View**.
2. In the **Endpoint Control** section select the message that you want to edit.
   The replacement message and its HTML code appear in a split screen in the lower half of the page.
3. Modify the text as needed and select **Save**.

Vulnerability Scan

The Network Vulnerability Scan helps you to protect your network assets (servers and workstations) by scanning them for security weaknesses. You can scan on-demand or on a scheduled basis. Results are viewable on the FortiGate unit, but results are also sent to an attached FortiAnalyzer unit. The FortiAnalyzer unit can collect the results of vulnerability scans from multiple FortiGate units at different locations on your network, compiling a comprehensive report about network security.

This section describes how to configure a single FortiGate unit for network scanning and how to view the results of the scan.

The following topics are included in this section:

- Configuring vulnerability scans
- Running a vulnerability scan and viewing scan results
- Requirements for authenticated scanning and ports scanned

Configuring vulnerability scans

You can configure the scan schedule and the assets to be scanned.

To configure scanning - web-based manager:

1. Go to **User & Device > Vulnerability Scan > Scan Definition**.
2. Beside **Schedule** select **Change** to set the scan schedule and mode:

Recurrence	Select **Daily**, **Weekly**, or **Monthly** and configure the details for the option you have selected.
Suspend Scan between	Set a time during which the scan should be paused if its running. (Optional)
Vulnerability Scan Mode	**Quick** — check only the most commonly used ports **Standard** — check the ports used by most known applications **Full** — check all TCP and UDP ports For a detailed list of the TCP and UDP ports examined by each scan mode, see Ports scanned in each scan mode on page 1964.

3. Select **Apply** to save the configuration.
4. In **Asset Definitions**, click Create New and enter information about the asset:

Name	Enter a name for this asset.
Type	Select **IP Address** to add a single IP address. Select **Range** to add a range of IP addresses to scan.
IP Address	Enter the IP address of the asset. (**Type** is **IP Address**.)
Range	Enter the start and end of the IP address range. (**Type** is **Range**.)
Enable Scheduled Vulnerability Scanning	Select to allow this asset to be scanned according to the schedule. Otherwise the asset is not scanned during a scheduled vulnerability scan.
Windows Authentication	Select to use authentication on a Windows operating system. Enter the username and password in the fields provided. For more information, see Requirements for authenticated scanning and ports scanned on page 1961.
Unix Authentication	Select to use authentication on a Unix operating system. Enter the username and password in the fields provided. For more information, see Requirements for authenticated scanning and ports scanned on page 1961.

To configure scanning - CLI:

To configure, for example, a standard scan to be performed every Sunday at 2:00am, you would enter:

```
config netscan settings
   set scan-mode standard
   set schedule enable
   set time 02:00
   set recurrence weekly
   set day-of-week sunday
end
```

To add an asset - CLI:

This example adds a single computer to the Asset list:

```
config netscan assets
   edit 0
      set name "server1"
      set addr-type ip
      set start-ip 10.11.101.20
      set auth-windows enable
      set win-username admin
      set win-password zxcvbnm
      set scheduled enable
   end
```

This example adds an address range to the Asset list. Authentication is not used:

```
config netscan assets
   edit 0
      set name "fileservers"
      set addr-type range
      set start-ip 10.11.101.160
      set end-ip 10.11.101.170
```

```
    set scheduled enable
end
```

Running a vulnerability scan and viewing scan results

To run a vulnerability scan - web-based manager:

1. Go to **User & Device > Vulnerability Scan > Scan Definition** and select **Start Scan**.
   When the scan is running you can pause or stop it at any time. You can also watch the progress of the scan.
2. When the scan is complete go to **User & Device > Vulnerability Scan > Vulnerability Result** to view the results of the scan.

To run a vulnerability scan - CLI:

Use the following CLI commands:

```
execute netscan start scan
execute netscan status
execute netscan pause
execute netscan resume
execute netscan stop
```

To view vulnerability scan results:

- To view vulnerability scan results go to **User & Device > Vulnerability Scan > Vulnerability Result**.

Select any log entry to view log details.

Requirements for authenticated scanning and ports scanned

The effectiveness of an authenticated scan is determined by the level of access the FortiGate unit obtains to the host operating system. Rather than use the system administrator's account, it might be more convenient to set up a separate account for the exclusive use of the vulnerability scanner with a password that does not change.

The following sections detail the account requirements for various operating systems.

Microsoft Windows hosts - domain scanning

The user account provided for authentication must

- have administrator rights
- be a Security type of account
- have global scope
- belong to the Domain Administrators group
- meet the Group Policy requirements listed below:

Group Policy - Security Options

In the Group Policy Management Editor, go to **Computer Configuration > Windows Settings > Security Settings > Local Policies > Security Options**.

Setting	Value
Network access: Sharing and security model for local accounts	Classic
Accounts: Guest account status	Disabled
Network access: Let Everyone permissions apply to anonymous users	Disabled

Group Policy - System Services

In the Group Policy Management Editor, go to **Computer Configuration > Windows Settings > Security Settings > System Services**.

Setting	Value
Remote registry	Automatic
Server	Automatic
Windows Firewall	Automatic

Group Policy - Administrative Templates

In the Group Policy Management Editor, go to **Computer Configuration > Administrative Templates > Network > Network Connections > Windows Firewall > Domain Profile**.

Setting	Value
Windows Firewall: Protect all network connections	Disabled

or

Setting	Value
Windows Firewall: Protect all network connections	Enabled
Windows Firewall: Allow remote administration exception	Enabled
Allow unsolicited messages from[1]	*
Windows Firewall: Allow file and printer sharing exception	Enabled
Allow unsolicited messages from[1]	*
Windows Firewall: Allow ICMP exceptions	Enabled
Allow unsolicited messages from[1]	*

[1]Windows prompts you for a range of IP addresses. Enter either "*" or the IP address of the Fortinet appliance that is performing the vulnerability scan.

Microsoft Windows hosts - local (non-domain) scanning

The user account provided for authentication must:

- be a local account
- belong to the Administrators group

The host must also meet the following requirements:

- Server service must be enabled. (Windows 2000, 2003, XP)
- Remote Registry Service must be enabled.
- File Sharing must be enabled.
- Public folder sharing must be disabled. (Windows 7)
- Simple File Sharing (SFS) must be disabled. (Windows XP)

Windows firewall settings

Enable the **Remote Administration Exception** in Windows Firewall. (Windows 2003, Windows XP)

Allow **File and Print sharing** and **Remote Administration** traffic to pass through the firewall. Specify the IP address or subnet of the Fortinet appliance that is performing the vulnerability scan. (Windows Vista, 2008)

For each of the active **Inbound Rules** in the **File and Printer Sharing** group, set the **Remote IP address** under **Scope** to either **Any IP address** or to the IP address or subnet of the Fortinet appliance that is performing the vulnerability scan. (Windows 7)

Unix hosts

The user account provided for authentication must be able at a minimum to execute these commands:

- The account must be able to execute "uname" in order to detect the platform for packages.
- If the target is running Red Hat, the account must be able to read /etc/redhat-release and execute "rpm".
- If the target is running Debian, the account must be able to read /etc/debian-version and execute "dpkg".

Ports scanned in each scan mode

Scan Type	Ports scanned
Standard Scan	**TCP:** 1-3, 5, 7, 9, 11, 13, 15, 17-25, 27, 29, 31, 33, 35, 37-39, 41-223, 242-246, 256-265, 280-282, 309, 311, 318, 322-325, 344-351, 363, 369-581, 587, 592-593, 598, 600, 606-620, 624, 627, 631, 633-637, 666-674, 700, 704-705, 707, 709-711, 729-731, 740-742, 744, 747-754, 758-765, 767, 769-777, 780-783, 786, 799-801, 860, 873, 886-888, 900-901, 911, 950, 954-955, 990-993, 995-1001, 1008, 1010-1011, 1015, 1023-1100, 1109-1112, 1114, 1123, 1155, 1167, 1170, 1207, 1212, 1214, 1220-1222, 1234-1236, 1241, 1243, 1245, 1248, 1269, 131t3-1314, 1337, 1344-1625, 1636-1774, 1776-1815, 1818-1824, 1901-1909, 1911-1920, 1944-1951, 1973, 1981, 1985-2028, 2030, 2032-2036, 2038, 2040-2049, 2053, 2065, 2067, 2080, 2097, 2100, 2102-2107, 2109, 2111, 2115, 2120, 2140, 2160-2161, 2201-2202, 2213, 2221-2223, 2232-2239, 2241, 2260, 2279-2288, 2297, 2301, 2307, 2334, 2339, 2345, 2381, 2389, 2391, 2393-2394, 2399, 2401, 2433, 2447, 2500-2501, 2532, 2544, 2564-2565, 2583, 2592, 2600-2605, 2626-2627, 2638-2639, 2690, 2700, 2716, 2766, 2784-2789, 2801, 2908-2912, 2953-2954, 2998, 3000-3002, 3006-3007, 3010-3011, 3020, 3047-3049, 3080, 3127-3128, 3141-3145, 3180-3181, 3205, 3232, 3260, 3264, 3267-3269, 3279, 3306, 3322-3325, 3333, 3340, 3351-3352, 3355,

Scan Type	Ports scanned
Standard Scan	**TCP Continued**: 3372, 3389, 3421, 3454-3457, 3689-3690, 3700, 3791, 3900, 3984-3986, 4000-4002, 4008-4009, 4080, 4092, 4100, 4103, 4105, 4107, 4132-4134, 4144, 4242, 4321, 4333, 4343, 4443-4454, 4500-4501, 4567, 4590, 4626, 4651, 4660-4663, 4672, 4899, 4903, 4950, 5000-5005, 5009-5011, 5020-5021, 5031, 5050, 5053, 5080, 5100-5101, 5145, 5150, 5190-5193, 5222, 5236, 5300-5305, 5321, 5400-5402, 5432, 5510, 5520-5521, 5530, 5540, 5550, 5554-5558, 5569, 5599-5601, 5631-5632, 5634, 5678-5679, 5713-5717, 5729, 5742, 5745, 5755, 5757, 5766-5767, 5800-5802, 5900-5902, 5977-5979, 5997-6053, 6080, 6103, 6110-6112, 6123, 6129, 6141-6149, 6253, 6346, 6387, 6389, 6400, 6455-6456, 6499-6500, 6515, 6558, 6588, 6660-6670, 6672-6673, 6699, 6767, 6771, 6776, 6831, 6883, 6912, 6939, 6969-6970, 7000-7021, 7070, 7080, 7099-7100, 7121, 7161, 7174, 7200-7201, 7300-7301, 7306-7308, 7395, 7426-7431, 7491, 7511, 7777-7778, 7781, 7789, 7895, 7938, 7999-8020, 8023, 8032, 8039, 8080-8082, 8090, 8100, 8181, 8192, 8200, 8383, 8403, 8443, 8450, 8484, 8732, 8765, 8886-8894, 8910, 9000-9001, 9005, 9043, 9080, 9090, 9098-9100, 9400, 9443, 9535, 9872-9876, 9878, 9889, 9989-10000, 10005, 10007, 10080-10082, 10101, 10520, 10607, 10666, 11000, 11004, 11223, 12076, 12223, 12345-12346, 12361-12362, 12456, 12468-12469, 12631, 12701, 12753, 13000, 13333, 14237-14238, 15858, 16384, 16660, 16959, 16969, 17007, 17300, 18000, 18181-18186, 18190-18192, 18194, 18209-18210, 18231-18232, 18264, 19541, 20000-20001, 20011, 20034, 20200, 20203, 20331, 21544, 21554, 21845-21849, 22222, 22273, 22289, 22305, 22321, 22555, 22800, 22951, 23456, 23476-23477, 25000-25009, 25252, 25793, 25867, 26000, 26208, 26274, 27000-27009, 27374, 27665, 29369, 29891, 30029, 30100-30102, 30129, 30303, 30999, 31336-31337, 31339, 31554, 31666, 31785, 31787-31788, 32000, 32768-32790, 33333, 33567-33568, 33911, 34324, 37651, 40412, 40421-40423, 42424, 44337, 47557, 47806, 47808, 49400, 50505, 50766, 51102, 51107, 51112, 53001, 54321, 57341, 60008, 61439, 61466, 65000, 65301, 65512 **UDP:** 7, 9, 13, 17, 19, 21, 37, 53, 67-69, 98, 111, 121, 123, 135, 137-138, 161, 177, 371, 389, 407, 445, 456, 464, 500, 512, 514, 517-518, 520, 555, 635, 666, 858, 1001, 1010-1011, 1015, 1024-1049, 1051-1055, 1170, 1243, 1245, 1434, 1492, 1600, 1604, 1645, 1701, 1807, 1812, 1900, 1978, 1981, 1999, 2001-2002, 2023, 2049, 2115, 2140, 2801, 3024, 3129, 3150, 3283, 3527, 3700, 3801, 4000, 4092, 4156, 4569, 4590, 4781, 5000-5001, 5036, 5060, 5321, 5400-5402, 5503, 5569, 5632, 5742, 6073, 6502, 6670, 6771, 6912, 6969, 7000, 7300-7301, 7306-7308, 7778, 7789, 7938, 9872-9875, 9989, 10067, 10167, 11000, 11223, 12223, 12345-12346, 12361-12362, 15253, 15345, 16969, 20001, 20034, 21544, 22222, 23456, 26274, 27444, 30029, 31335, 31337-31339, 31666, 31785, 31789, 31791-31792, 32771, 33333, 34324, 40412, 40421-40423, 40426, 47262, 50505, 50766, 51100-51101, 51109, 53001, 61466, 65000

Chapter 20 - Managing a FortiSwitch with a FortiGate

Managing a FortiSwitch with a FortiGate

Introduction

This document describes how to use FortiGate to remotely manage FortiSwitch units, which is also known as using a FortiSwitch in FortiLink mode. FortiLink defines the management interface and the remote management protocol between the FortiGate and FortiSwitch.

FortiGate supports remote management for up to 16 FortiSwitches.

Supported Models

The following table shows the FortiSwitch models that support FortiLink mode when paired with the corresponding FortiGate models and the listed minimum software releases.

FortiSwitch	FortiGate	Earliest FortiSwitchOS	Earliest FortiOS
FS-224D-POE	FGT-90D(Wifi/poe) + FGT-Models1	3.0.0	5.2.2
FS-108D-POE	FGT-60D(all) + FGT-Models1	3.0.1	5.2.3
FSR-112D-POE	FGR-90D + FGT-Models1	3.0.1	5.2.3
FS-124D	FGT-90D + FGT-60D + FGT-Models1	3.0.1	5.2.3
FS-124D-POE	FGT-90D + FGT-60D + FGT-Models1	3.0.1	5.2.3
FS-224D-FPOE	FGT-90D + FGT-60D + FGT-Models1	3.0.1	5.2.3

FortiGate models 1 includes the following: 100D/200D/240D/140D(POE, T1),280D(POE)/600C/800C/1000C

Before You Begin

Before you set up remote management of your FortiSwitch unit, certain assumptions have been made in the writing of this manual:

- You have installed a FortiGate unit on your network and have administrative access to the FortiGate web-based manager and CLI.

How this Guide is Organized

This guide contains the following sections:

Getting Started - describes how to configure the FortiGate for remote management of the FortiSwitch units.

VLAN Configuration - configure VLANs from the FortiGate unit.

Port Configuration - configure Ports from the FortiGate unit.

Scenarios - contains practical examples of how to use the FortiGate unit to manage a network of FortiSwitches.

Getting Started

This chapter describes how to configure the FortiGate to provide remote management for FortiSwitch units.

The FortiGate requires a one-time configuration task to enable the Switch Controller on the FortiGate.

Adding a new managed FortiSwitch is very simple. You connect a cable from a port on the FortiGate to the designated FortiLink port on the FortiSwitch. Using the FortiGate GUI, you then set two simple configuration settings. No configuration changes are required on the FortiSwitch (one change is required in FortiSwitchOS releases prior to 3.3.0).

Optionally, you can also configure remote management access directly to the FortiSwitch.

Enable the Switch Controller on FortiGate

Prior to configuring the first managed FortiSwitch, you must enable the Switch Controller on the FortiGate unit. If the main left menu already contains the **WiFi & Switch Controller** entry, you can skip this step.

Using the FortiGate web-based manager

1. Go to **System > Config > Features**.
2. Set the **WiFi & Switch Controller** feature to **on**.
3. Select **Apply**.

The menu now includes the **WiFi & Switch Controller** entry.

Using the FortiGate CLI

Use the following command to enable the Switch Controller and set the reserved subnetwork for the controller:

```
config system global
   set switch-controller enable
   set switch-controller-reserved-network 169.254.254.0 255.255.255.0
end
```

Adding a Managed FortiSwitch with FortiGate GUI

The procedure to add a new managed FortiSwitch consists of the following simple steps using the FortiGate GUI:

Note: For FortiSwitchOS releases prior to 3.3.0, you must Set the FortiSwitch to remote management mode prior to starting step 1

1. Connect a cable from the designated FortiSwitch port to an unused port on the FortiGate. For example, use port 24 on the FS-224D-POE switch. Refer to FortiLink Port for each FortiSwitch Model for additional information.
2. Go to **System > Network > Interfaces** and edit an internal port on the FortiGate.
3. Set **Addressing mode** to **Dedicate to Extension Device**.
4. Select **OK**.
5. Go to **WiFi & Switch Controller > Managed Devices > Managed FortiSwitch**.
   The new FortiSwitch should now be displayed in the table.
6. Right-click on the FortiSwitch and select **Authorize**.

After a delay (while FortiGate processes the request), an icon with a green checkmark appears in the Status column. For smaller FortiSwitch models, such as FS-108D-POE, the delay may be up to 3 minutes.

Set the FortiSwitch to remote management mode

Use the FortiSwitch web-based manager or the CLI to set remote management mode.

Note: This configuration step is not required in FortiSwitchOS release 3.3.0 or later releases.

Using the FortiSwitch web-based manager

1. Go to **System > Dashboard > Status** and locate the **System Information** widget.
2. Beside **Operation Mode**, select **Change**.
3. Change **Management Mode** to **FortiGate Remote Management**.
4. Select **OK**.
5. A warning will appear, asking if you wish to continue. Select **OK**.

Using the FortiSwitch CLI

Use the following command to change the FortiSwitch management mode:

```
config system global
   set switch-mgmt-mode fortilink
end
```

The FortiSwitch unit is now ready to be connected to the FortiGate unit.

FortiLink Port for each FortiSwitch Model

Each FortiSwitch model provides one designated port for the FortiLink connection. The table below lists the FortiLink port for each model:

FortiSwitch Model	Port for FortiLink connection
FS-28C	WAN port 1
FS-324B-POE	Management Port
FS-448B (10G only)	WAN port (uplink 1)
FS-348B	Last port (port 48)
For all D-series switches, use the last (highest number) port for FortiLink. For example:	
FS-108D-POE	Last port (port 10)
FSR-112D-POE	Last port (port 12)
FS-124D	Last port (port 26). May require an SFP module. See note below the table.
FS-224D-POE	Last port (port 24)
FS-224D-FPOE	Last port (port 28). May require an SFP module. See note below the table.

Note: FortiSwitch 3.3.1 and later releases support the use of an RJ-45 port for FortiLink.
Please contact Fortinet Customer Support for additional information.

FortiLink Ports for Each FortiGate Model

For all FortiGate models, you can connect up to 16 FortiSwitches to one FortiGate unit.

The following table shows the ports for each model of FortiGate that can be FortiLink-dedicated.

FortiGate Model	Ports for FortiLink connection
FGT-90D, FGT-90D-POE FWF-90D, FWF-90D-POE	port1 - port14
FGT-60D, FGT-60D-POE FWF-60D, FWF-60D-POE	port1 - port7
FGT-100D	port1 - port16
FGT-140D , 140D-POE, 140D-POE-T1	port1 - port36
FGT-200D	port1 - port16
FGT-240D	port1 - port40
FGT-280D, FGT-280D-POE	port1 - port84
FGT-600C	port3 - port22
FGT-800C	port3 - port24
FGT-1000C	port3 - port14, port23 - port24

Adding a Managed FortiSwitch with FortiGate CLI

We recommend that you add a new managed FortiSwitch using the FortiGate GUI. However, the following steps show how to add a new managed FortiSwitch using the FortiGate CLI. In these steps, the FortiGate port1 is configured as the FortiLink port:

1. If required, remove port 1 from the **lan** interface:

```
config system virtual-switch
   edit lan
      config port
         delete port1
      end
   end
end
```

2. Configure the interface for port 1.

```
config system interface
   edit port1
      set ip 172.20.120.10 255.255.255.0
      set allowaccess capwap
      set vlanforward enable
   end
end
```

3. Configure an NTP server on port 1.

```
config system ntp
   set server-mode enable
   set interface port1
end
```

4. Authorize the FortiSwitch unit as a managed switch.

```
config switch-controller managed-switch
   edit FS224D3W14000370
      set fsw-wan1-admin enable
   end
end
NOTE: FortiSwitch will reboot when you issue the above command.
```

5. Configure a DHCP server on port 1.

```
config system dhcp server
   edit 0
      set netmask 255.255.255.252
      set interface port1
      config ip-range
         edit 0
            set start-ip 169.254.254.2
            set end-ip 169.254.254.50
         end
      set vci-match enable
      set vci-string FortiSwitch
      set ntp-service local
   end
end
```

Configuring FortiSwitch Remote Management Port

If the FortiSwitch model has a dedicated management port, you can configure remote management to the FortiSwitch. In FortiLink mode, the FortiGate is the default gateway, so you need to configure an explicit route for the FortiSwitch management port.

From the FortiSwitch CLI, enter the following commands:

```
config router static
   edit 1
      set device mgmt
      set gateway <router IP address>
      set dst <router subnet> <subnet mask>
   end
end
```

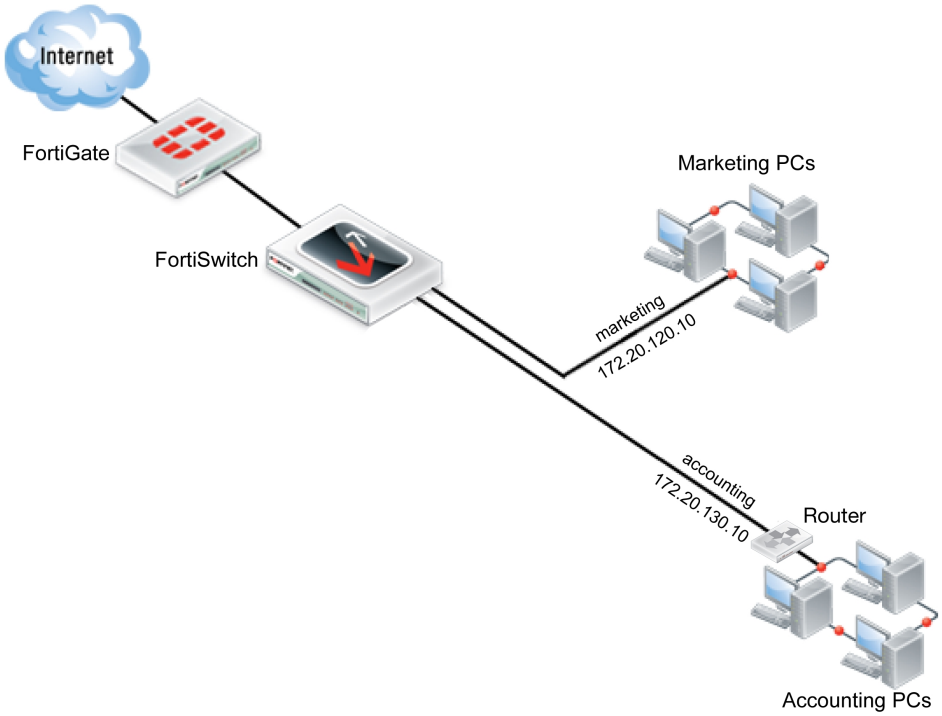
In the following example, the FortiSwitch management port is connected to a router with IP address 192.168.0.10:

```
config router static
   edit 1
      set device mgmt
      set gateway 192.168.0.10
      set dst 192.168.0.0 255.255.0.0
   end
end
```

VLAN Configuration

Using Virtual Local Area Networks (VLANs) allows you to get the most out of using your FortiSwitch unit by using ID tags to logically separate a LAN into smaller broadcast domains. A single LAN can contain many unique VLANs, which allows different policies to be created for different types of users and segments traffic so that it is only sent to and from the intended VLAN.

For example, if a company has one LAN which is to be used for both the marketing and the accounting department, this LAN can be segmented into two VLANs. This allows the traffic from each department to be isolated, so information packets sent to the marketing department are only sent on the marketing VLAN. It also allowed different policies to be created, so that security can be increased for the accounting department without also increasing it for the marketing department.



Now that your FortiSwitch unit is managed by your FortiGate unit, a VLAN can be configured on the FortiSwitch, using the FortiGate.

The following instructions will create a VLAN to be used by the marketing team for network and Internet access. The PCs used by the marketing team will connect to ports 3-6 on the FortiSwitch unit.

Setting up a VLAN requires:

- Creating the VLAN.
- Assigning ports on the FortiSwitch unit to the VLAN.

Creating VLANs

Using the web-based manager

Creating the VLAN

1. Go to **WiFi & Switch Controller** > **Switch Network** > **Virtual Switch** and select **Create New**. Change the following settings:

Name	marketing
Color	
IP/Network Mask	172.20.120.10/255.255.255.0

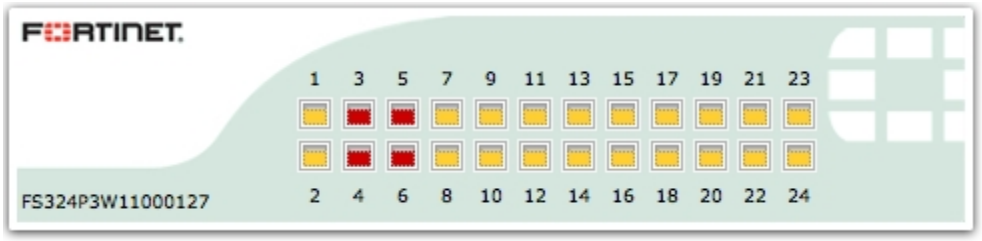
1. Enable **DHCP Server.** Set the IP range to 172.20.120.11-172.20.120.254.
2. Select **OK**.

The entry **marketing** is now shown on the list of **Virtual Switches**. A **marketing** interface has also been added, which can be seen by going to **System > Network > Interfaces**.

Assigning FortiSwitch Ports to the VLAN

1. Go to **WiFi & Switch Controller** > **Managed Devices** > **Managed FortiSwitch**
2. Highlight the FortiSwitch unit and select **Edit Managed FortiSwitch**.
3. Click and drag a box around ports 3-6 to select them.
4. Select **marketing** from the **Assign to** list.

Ports 3-6 on the FortiSwitch have now been assigned to the marketing VLAN and will appear in red.



Using the CLI

1. Create the marketing VLAN.

```
config switch-controller vlan
   edit marketing
      set color 32
end
```

2. Set the VLAN's IP address.

```
config system interface
   edit marketing
      set ip 172.20.120.14 255.255.255.0
end
```

3. Enable a DHCP Server.

```
config system dhcp server
   edit 1
      set default-gateway 172.20.120.10
      set dns-service default
      set interface marketing
         config ip-range
            set start-ip 172.20.120.11
            set end-ip 172.20.120.254
         end
      set netmask 255.255.255.0
end
```

4. Assign ports 3-6 to the VLAN.

```
config switch-controller managed-switch
   edit FS224D3W14000370
      config ports
         edit port3
            set vlan marketing
         next
         edit port4
            set vlan marketing
         next
         edit port5
            set vlan marketing
         next
         edit port6
            set vlan marketing
      end
end
```

Setting up a security policy for the VLAN

The following instructions configure a basic security policy for the marketing VLAN that will allow all traffic from the marketing VLAN to have access to the Internet.

Using the web-based manager

1. Go to **Policy & Objects** > **Policy > IPv4** and select **Create New**. Change the following settings:

Incoming Interface	marketing
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Enable NAT	Enable
Logging Options	Log all Sessions

2. Select **OK**.

With this security policy in place, all computers connected to the marketing VLAN can now access the Internet.

Using the CLI

Create a security policy for the marketing VLAN.

```
config security policy
   edit 2
      set srcintf marketing
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set logtraffic all
      set nat enable
end
```

Port Configuration

You can configure the FortiSwitch port and POE settings from the FortiGate using CLI commands. Currently, these functions are not available in the FortiGate web-based manager.

The following port CLI commands are available:

- Set port speed.
- Set port admin status
- Configure vlan on the port

Port CLI commands

```
config switch-controller
   edit <switch>
      config ports
         edit <port>
            speed <speed>
            status {down | up}
            vlan <vlan_id>
```

Scenarios

This chapter contains practical examples of how to use the FortiSwitch unit to manage a network. The scenarios are as follows:

- Scenario 1: Allowing access to specific users on the marketing VLAN
- Scenario 2: Adding a specific device to the marketing VLAN
- Scenario 3: Accessing the marketing VLAN remotely using an SSL VPN
- Scenario 4: Configuring the accounting VLAN using an SFP port
- Scenario 5: Connecting a VoIP phone to the FortiSwitch
- Scenario 6: Connecting a FortiAP unit to the FortiSwitch

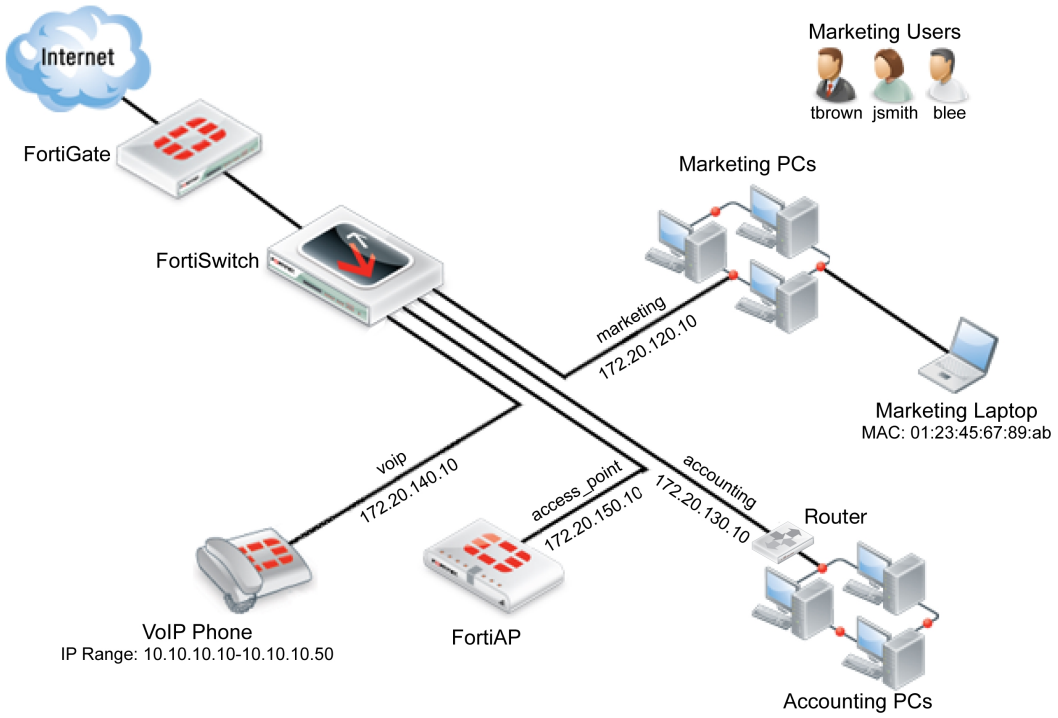
The Example Network

All the scenarios are interrelated and are used to manage an example network with the following attributes:

- The FortiSwitch unit used is a FortiSwitch-224D-POE, serial number FS224D3W14000370.
- The FortiSwitch unit's port 24 connects to port1 on the FortiGate unit.
- The LAN is divided into four distinct VLANs, configured as follows:

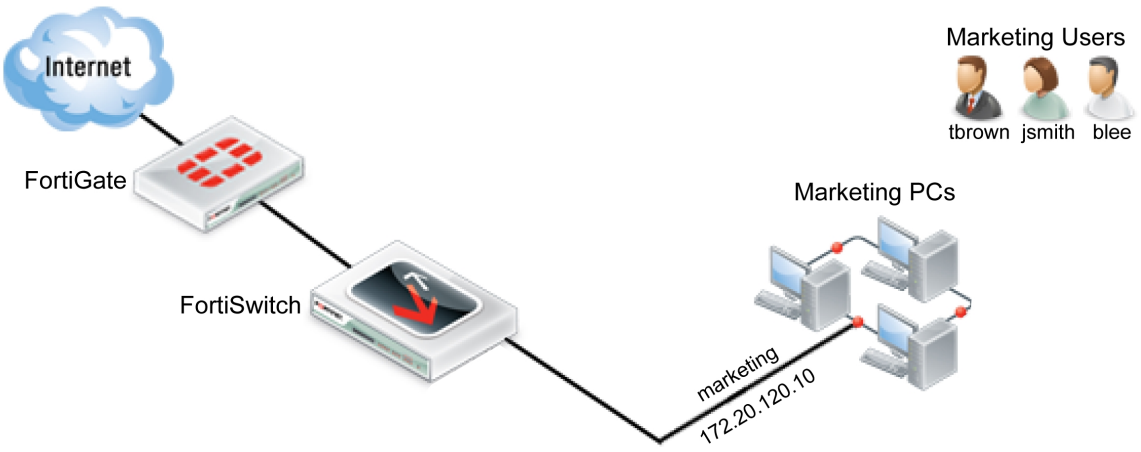
VLAN	IP	Device(s)	Port(s)	Policy ID(s)	GUI Color
marketing	172.20.120.10/255.255.255.0	marketing PCs, marketing laptop	3-6	2, 3	
accounting	172.20.130.10/255.255.255.0	accounting PCs	21	4	
voip	172.20.140.10/255.255.255.0	VoIP phone	10	5	
access_point	172.20.150.10/255.255.255.0	FortiAP	1	6	

- There are six devices that connect directly to the FortiSwitch unit's ports using Ethernet cables: the 3 marketing PCs, the marketing laptop, the VoIP phone, and the FortiAP unit.
- The accounting VLAN connects to the FortiSwitch using an SFP port.
- There are three marketing employees (Jane Smith, Tom Brown, Bob Lee) who will use the marketing VLAN using the marketing PCs.
- The MAC address of the marketing laptop is 01:23:45:67:89:ab.
- The IP range for the VoIP phone is 10.10.10.10-10.10.10.50.
- The FortiAP unit is a FortiAP-11C, serial number FAP11C3X12000412.



Scenario 1: Allowing access to specific users on the marketing VLAN

In Scenario 1, the policies for the marketing VLAN will be created so that different users have different access. The firewall policy will be created so that all three marketing employees (Jane Smith, Tom Brown, Bob Lee) have user accounts. These accounts will be put into one of two groups: full-time and part-time. Full-time employees will always have network access, while part-time employees will only have access on Mondays, Wednesdays and Fridays. This policy will apply to each user when they use any of the PCs that connect to the marketing VLAN through ports 3, 4, 5 or 6 on the FortiSwitch.



Creating a policy to match scenario 1 requires:

- Creating users.
- Creating groups.
- Creating a schedule.
- Configuring the firewall policies.

Using the web-based manager

Creating a User Group

1. Go to **User & Device** > **User** > **User Groups** and select **Create New**.
2. Name the user group **part-time**.
3. Set **Type** as **Firewall**.
4. Select **OK**.

The entry **part-time** will now appear on the user group list. Repeat these steps to create another user group, named **full-time**.

Creating a User

1. Go to **User & Device** > **User** > **User Definition**. Select **Create New**.
2. Use the **User Creation Wizard** to create a user. In part 1, select **Local User**.
3. In part 2, change the following settings:

User Name	blee
Password	password

4. In part 3, enter the email address blee@example.com
5. In part 4, select **Enable** and **User Group**. Set **part-time** as the group.
6. Select **Done**.

The entry **blee** will now appear in the user list. Repeat these steps to create user accounts **tbrown** and **jsmith** and add both of these accounts to the **full-time group.**

Creating a Schedule

1. Go to **Policy & Objects** > **Objects** > **Schedules**. Select **Create New** and then select **Recurring**.
2. Change the following settings:

Name	part-time_schedule
Day of the Week	Monday, Wednesday, Friday

3. Select **OK**.

The entry **part-time schedule** will now appear on the schedules list.

Configuring the Firewall Policy

1. Go to **Policy & Objects** > **Policy** > **IPv4** and select **Create New**.
2. Set the policy to use the following the following settings, allowing access for part-time employees:

Incoming Interface	marketing
Source Address	all
Source User(s)	part-time
Outgoing Interface	wan1
Destination Address	all
Schedule	part-time_schedule
Service	ALL
Action	ACCEPT
Enable NAT	Enable
Logging Options	Log all Sessions

3. Select **OK**.
4. Go to **Policy & Objects** > **Policy> IPv4** and create a new policy.
5. Change the following settings to set access for full-time employees:

Incoming Interface	marketing
Source Address	all
Source User(s)	full-time
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Enable
Logging Options	Log all Sessions

6. Select **OK**.

You have now finished creating the policies that match scenario 1. These policies will apply to all three users when they use any of the PCs that connect to the marketing VLAN.

Using the CLI

1. Create the 3 users.

```
config user local
   edit blee
      set type password
      set passwd password
```

```
   next
   edit tbrown
      set type password
      set passwd password
   next
   edit jsmith
      set type password
      set passwd password
end
```

2. Create the 2 user groups and add the users to them.

```
config user group
   edit part-time
      set group-type firewall
      set member blee
next
   edit full-time
      set group-type firewall
      set member tbrown jsmith
end
```

3. Create the schedule for part-time employees.

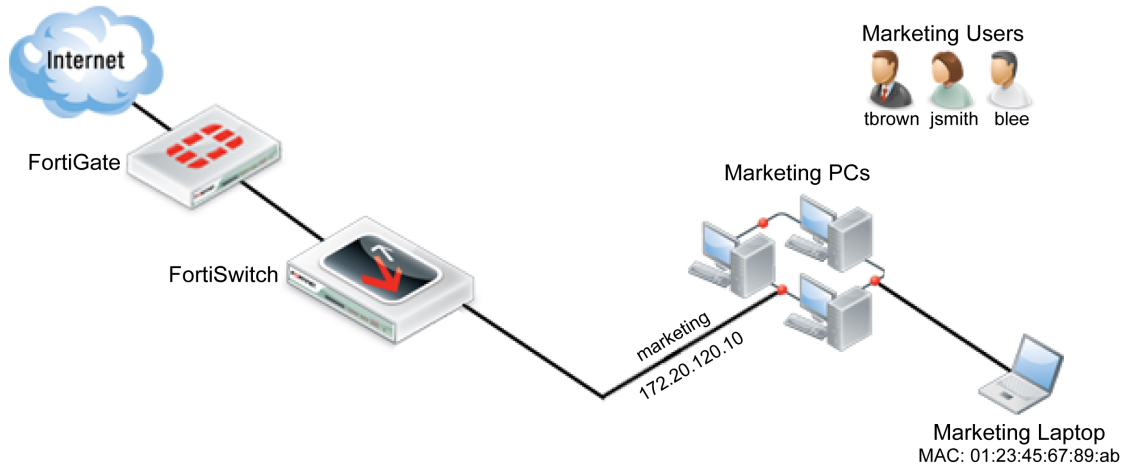
```
config firewall schedule recurring
   edit part-time_schedule
      set day monday wednesday friday
end
```

4. Create two firewall policies for the marketing VLAN, one for each user group:

```
config firewall policy
   edit 2
      set srcintf marketing
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set nat enable
      set action accept
      set schedule part-time_schedule
      set logtraffic all
      set groups part-time
      set service ALL
   next
   edit 3
      set srcintf marketing
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set nat enable
      set action accept
      set schedule always
      set logtraffic all
      set groups full-time
      set service ALL
end
```

Scenario 2: Adding a specific device to the marketing VLAN

In Scenario 2, a new policy will be created for the marketing VLAN that will be used by the marketing laptop. This policy will affect the marketing laptop that is used periodically for tasks such as boardroom presentations or for guests, tasks for which the laptop requires Internet access. The laptop will access the Internet by connecting to the marketing VLAN through ports 3, 4, 5 or 6 on the FortiSwitch. Adding a new policy for the laptop will allow it to connect without requiring user authentication and will also limit the scope of the device's access.



Creating a policy to match scenario 2 requires:

- Assigning a reserve IP to the laptop.
- Creating a firewall address for the reserve IP.
- Creating a firewall policy that uses the reserve IP.

Using the web-based manager

Assigning a Reserve IP to the Laptop

1. Go to **System > Network > Interfaces** and select **marketing**.
2. Under **DHCP Server**, expand the **Advanced** options.
3. In the **MAC Address Access Control List** and select **Create New**.
4. Change the following settings:

MAC	01:23:45:67:89:ab
IP	172.20.120.254
Action	Reserve IP

Creating a Firewall Address for the Reserve IP

1. Go to **Policy & Objects > Objects > Addresses** and select **Create New**.
2. Change the following settings:

Category	Address
Name	marketing_laptop
Type	Subnet
Subnet/IP Range	172.20.120.254
Interface	marketing

Configuring a Firewall Policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**.
2. Change the following settings:

Incoming Interface	marketing
Source Address	marketing_laptop
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	HTTP HTTPS DNS
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

3. Select **OK.**
4. In the policy list, select the column on the far left for the new policy (usually **Seq #)** and drag the policy above the previous policy for the marketing VLAN. This will ensure that the laptop will be identified through this policy.

You have now finished creating a policy that matches scenario 2. This policy will apply to anyone who uses the laptop to connect to the **marketing** VLAN using an Ethernet cable.

Using the CLI

1. Assign a reserve IP to the laptop.

```
config system dhcp server
   edit 2
      config reserved-address
         edit 1
            set action reserved
            set ip 172.20.120.254
            set mac 01:23:45:67:89:ab
      end
end
```

2. Create a firewall address for the reserve IP.

```
config firewall address
```

```
   edit marketing_laptop
      set subnet 172.20.120.254
end
```

3. Create a firewall policy for the marketing VLAN that uses the reserve IP.

```
config firewall policy
   edit 4
      set srcintf marketing
      set dstintf wan1
      set srcaddr marketing_laptop
      set dstaddr all
      set action accept
      set schedule always
      set service HTTP HTTPS DNS
      set logtraffic all
      set nat enable
end
```

4. Place the new firewall policy at the top of the policy list.

```
config firewall policy
   move 4 before 2
end
```

Scenario 3: Accessing the marketing VLAN remotely using an SSL VPN

In Scenario 3, a policy is created to allow remote access to the marketing VLAN, using a virtual private network (VPN) tunnel. This policy will allow marketing employee Tom Brown to connect to the marketing VLAN remotely from his home. The default IP Pool, **SSLVPN_TUNNEL_ADDR1**, will be used to configure the SSL VPN web portal. The computer Tom Brown is using to access the network remotely has a dynamic IP address and will be using the FortiClient application to auto connect to the VPN tunnel. To maintain security, split tunneling will be disabled. This policy will be used whenever Tom Brown accesses the marketing VLAN remotely.

Creating a policy to match scenario 3 requires:

- Creating a user group.
- Creating a firewall address for the marketing VLAN.
- Creating an SSL VPN portal.
- Creating a SSL VPN firewall policy for the marketing VLAN.

Using the web-based manager

Creating a User Group

1. Go to **User & Device** > **User** > **User Groups** and select **Create New**.
2. Name the Group **remote access**.
3. Set **Type** as **Firewall**.
4. Highlight **tbrown** on the **Available Users** list.
5. Select the right-pointing arrow to move **tbrown** to the **Members** list.
6. Select **OK**.

The entry **remote access** will now appear on the **Group** list, with **tbrown** listed under **Members**.

Creating a Firewall Address for the marketing VLAN

1. Go to **Policy & Objects** > **Objects** > **Addresses** and select **Create New**. Change the following settings:

Address Name	marketing VLAN
Type	Subnet
Subnet/IP Range	172.20.120.14/255.255.255.0
Interface	marketing

2. Select **OK**.

Creating an SSL VPN Portal

1. Go to **VPN** > **SSL** > **Portals** and select **Create New**. Change the following settings:

Name	marketing-remote
Enable Tunnel Mode	Enable
Enable Split Tunneling	Disable
IP Pools	SSLVPN_TUNNEL_ADDR1
Enable Web Mode	Enable

2. Select **Apply**.

Creating a Firewall Policy

1. Go to **Policy & Objects** > **Policy > IPv4** and select **Create New.**
2. Change the following settings to allow Tom Brown to access the marketing VLAN:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	marketing_laptop
Outgoing Interface	marketing
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

3. Select **OK**.
4. Go to **Policy & Objects** > **Policy > IPv4** and create a second policy.
5. Change the following settings to allow Tom Brown to access the Internet through the FortiGate:

Incoming Interface	ssl.root (sslvpn tunnel interface)
Source Address	marketing_laptop
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	HTTP HTTPS DNS
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

6. Select **OK**.

The FortiClient SSL VPN tunnel client will also need to be configured, in order for the Tom Brown to connect to the SSL VPN tunnel.

You have now finished creating a policy that matches scenario 4. This policy will be used whenever Tom Brown accesses the marketing VLAN remotely.

Using the CLI

1. Create the user group for remote users.

```
config user group
   edit remote-access
      set group-type firewall
      set member tbrown
end
```

2. Create a firewall address for the marketing VLAN.

```
config firewall address
   edit marketing_VLAN
      set associated-interface marketing
      set subnet 172.20.120.14 255.255.255.0
end
```

3. Create the SSL VPN web portal.

```
config vpn ssl web portal
   edit marketing-remote
      set allow-access web ftp ssh
      config widget
         edit 1
```

```
            set type tunnel
            set split-tunneling disable
            set ip-pools SSLVPN_TUNNEL_ADDR1
            set auto-connect enable
        end
end
```

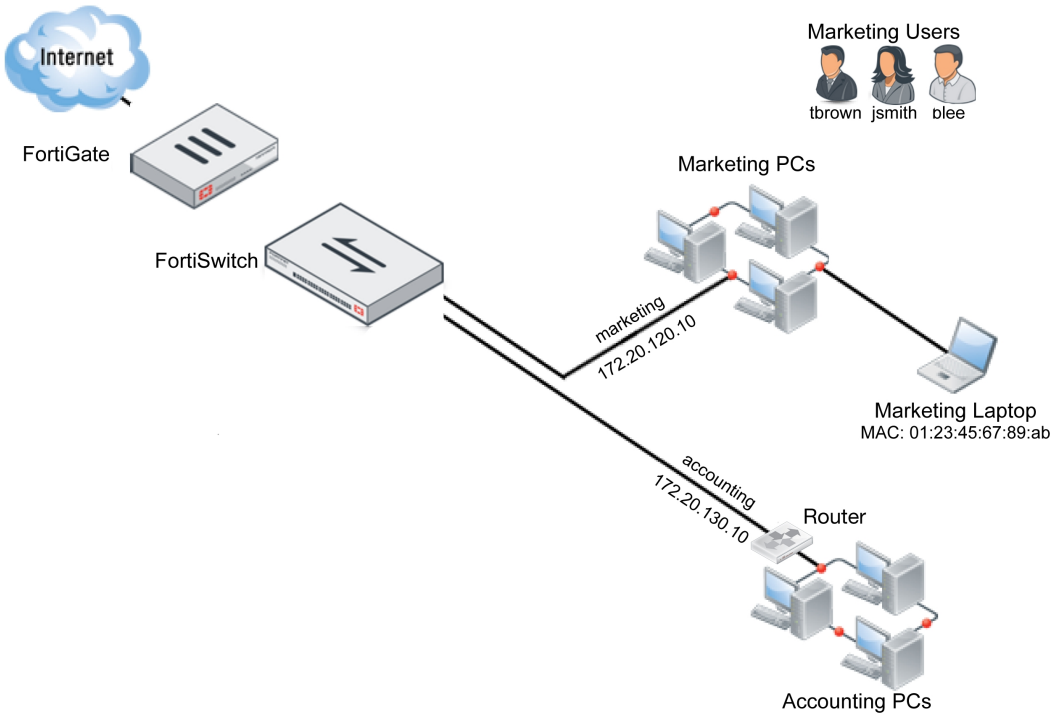
4. Create a firewall policy to allow remote access to the marketing VLAN.

```
config firewall policy
   edit 3
      set srcintf wan1
      set dstintf marketing
      set dstaddr marketing_VLAN
      set action ssl-vpn
      set schedule always
      set groups remote_access
      set users tbrown
      set sslvpn-portal marketing-remote
end
```

Scenario 4: Configuring the accounting VLAN using an SFP port

The SFP ports should only be used to connect UL-listed optical transceiver products, rated Laser Class 1.33V DC.

In Scenario 4, a second VLAN will be created on the FortiSwitch, to be used for the accounting department. This VLAN will connect to the FortiSwitch unit using a copper SFP receiver that has been installed in the FortiSwitch. Due to the sensitive nature of information within the accounting network, the firewall policy that controls traffic to this network uses the default profile for all security features.



Creating an interface to match scenario 4 requires:

- Creating and assigning a VLAN.
- Configuring a firewall policy.

SFP ports are only available on certain FortiSwitch models. SFP ports are also shared with Ethernet ports and so when an SFP port is used, the Ethernet port with the same number cannot be.

Using the web-based manager

Creating and Assigning the VLAN

1. Go to **WiFi & Switch Controller** > **Switch Network** > **Virtual Switch** and select **Create New**. Change the following settings:

Name	accounting
Color	
IP/Network Mask	172.20.130.15/255.255.255.0

2. Select **OK**.
3. Go to **WiFi & Switch Controller** > **Managed Devices** > **Managed FortiSwitch** and assign FortiSwitch **port 21** to **accounting**.

Configuring the Firewall Policy

1. Go to **Policy & Objects** > **Policy > IPv4** and select **Create New**. Change the following settings:

Incoming Interface	accounting
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

2. Enable the following Security Profiles and set them to use the **default** profile: **AntiVirus**, **Web Filter**, **Application Control**, **IPS**, **Email Filter**, **DLP Sensor**, and **SSL/SSH Inspection**.
3. Select **OK**.

You have now finished creating a policy that matches scenario 5. This policy will be used for all traffic on the accounting VLAN.

Using the CLI

1. Create the accounting VLAN.

```
config switch-controller vlan
   edit accounting
      set color 32
end
```

2. Set the VLAN's IP address.

```
config system interface
   edit marketing
      set ip 172.20.130.15 255.255.255.0
end
```

3. Assign the accounting VLAN to port 21.

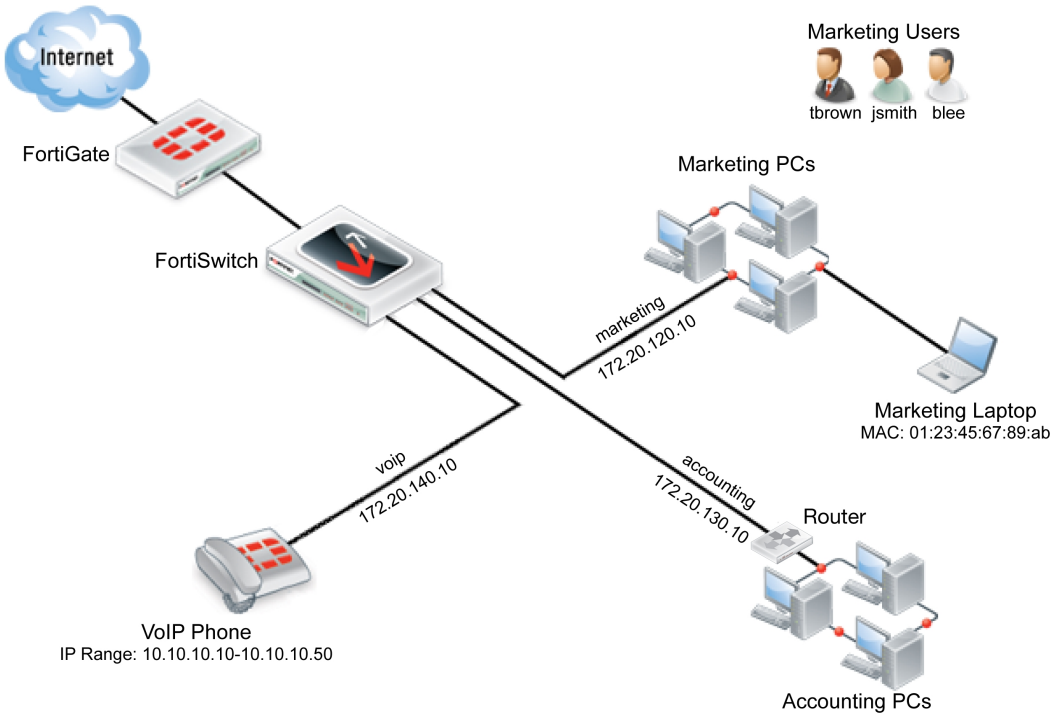
```
config switch-controller managed-switch
   edit FS224D3W14000370
      config ports
         edit port21
            set vlan accounting
      end
end
```

4. Create a firewall policy for the accounting VLAN that uses the default security profiles.

```
config firewall policy
   edit 4
      set srcintf accounting
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set logtraffic all
      set nat enable
      set av-profile default
      set webfilter-profile default
      set spamfilter-profile default
      set dlp-sensor default
      set ips-sensor default
      set application-list default
      set profile-protocol-options default
      set deep-inspection-options default
end
```

Scenario 5: Connecting a VoIP phone to the FortiSwitch

In Scenario 5, an interface will be configured to use a Voice over IP (VoIP) phone. This VoIP phone will be assigned the IP range 10.10.10.10-10.10.10.50 and connect to the FortiSwitch unit through port 10 using an Ethernet cable. The FortiGate unit's default VoIP profile will be used.



Creating an interface to match scenario 5 requires:

- Creating and assigning a VLAN.
- Creating a firewall address for the VoIP phone.
- Configuring a firewall policy.

Using the web-based manager

Creating and Assigning the VLAN

1. Go to **WiFi & Switch Controller** > **Switch Network** > **Virtual Switch** and select **Create New**. Change the following settings:

Name	voip
Color	
IP/Network Mask	172.20.140.16/255.255.255.0

2. Select **OK**.
3. Go to **WiFi & Switch Controller** > **Managed Devices** > **Managed FortiSwitch** and assign FortiSwitch **port10** to **voip**.

Creating a Firewall Address

1. Go to **Policy & Objects** > **Objects** > **Addresses** and select **Create New**. Change the following settings:

Category	Address
Name	voip
Color	
Type	IP Range
Subnet/IP Range	10.10.10.10-10.10.10.50
Interface	voip

2. Select **OK**.

Create a Firewall Policy

1. Go to **Policy & Objects > Policy > IPv4** and select **Create New**. Change the following settings:

Incoming Interface	voip
Source Address	voip_phone
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

2. Go to **Policy & Objects** > **Policy > IPv4** and select **Create New**. Change the following settings:
3. Enable the **VoIP** Security Profile and set it to **default**.

You have now finished creating a policy that matches scenario 6.

Using the CLI

1. Create the voip VLAN.

```
config switch-controller vlan
   edit voip
      set color 25
end
```

2. Set the VLAN's IP address.

```
config system interface
   edit marketing
      set ip 172.20.140.16 255.255.255.0
end
```

3. Assign the voip VLAN to port 10.

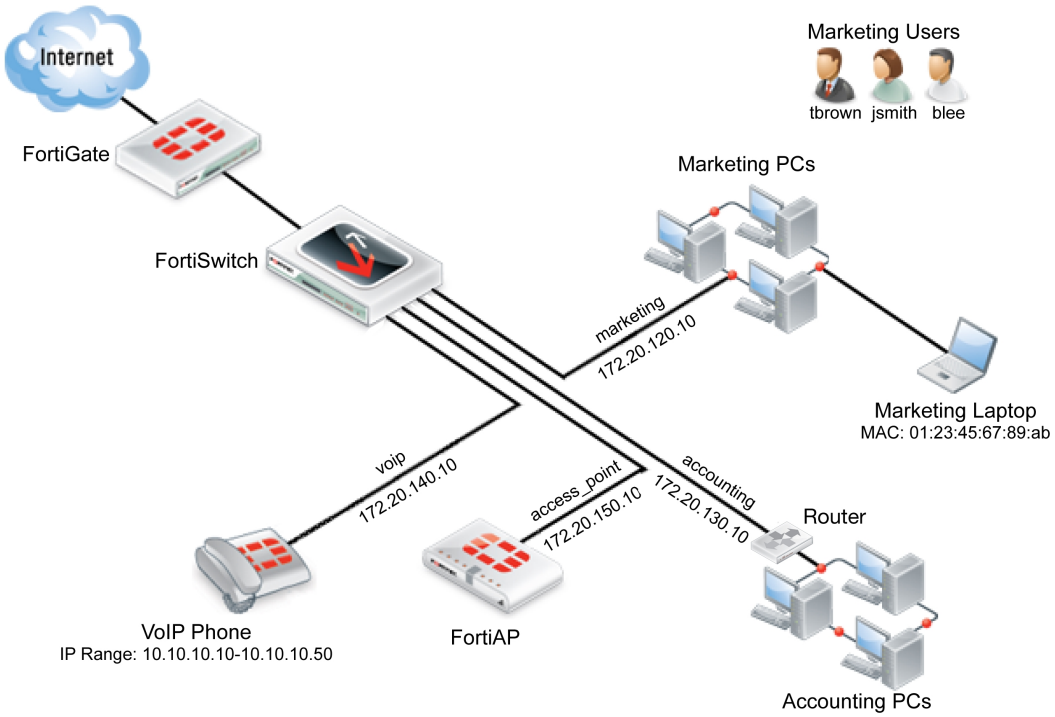
```
config switch-controller managed-switch
   edit FS224D3W14000370
      config ports
         edit port10
            set vlan voip
      end
end
```

4. Configure the firewall policy.

```
config firewall policy
   edit 5
      set srcintf voip
      set dstintf wan1
      set srcaddr voip_phone
      set dstaddr all
      set action accept
      set schedule always
      set service SIP
      set logtraffic all
      set nat enable
      set voip-profile default
end
```

Scenario 6: Connecting a FortiAP unit to the FortiSwitch

In Scenario 6, an interface will be configured to use a FortiAP unit that will provide wireless Internet access.



Creating an interface to match scenario 6 requires:

- Creating and assigning a VLAN.
- Authorizing the FortiAP unit.

- Creating an SSID.
- Creating a firewall address.
- Configuring a firewall policy.

The WiFi network provided by the access point will use the marketing schedule and allow HTTP and HTTPS traffic.

Using the web-based manager

Creating and Assigning the VLAN

1. Go to **WiFi & Switch Controller** > **Switch Network** > **Virtual Switch** and select **Create New**. Change the following settings:

Name	access_point
Color	
IP/Network Mask	172.20.150.17/255.255.255.0
DHCP Server	Enable

2. Select **OK**.
3. Go to **WiFi & Switch Controller** > **Managed Devices** > **Managed FortiSwitch** and assign FortiSwitch **port1** to **access_point.**

Authorizing the FortiAP unit

1. Go to **WiFi & Switch Controller > Managed Devices > Managed FortiAPs**.
2. Right-click on the FortiAP unit and select **Authorize**.

A icon with a checkmark now appears in the Status column.

Creating an SSID

1. Go to **WiFi & Switch Controller > WiFi Network > SSIDs** and select **Create New.**
2. Change the following settings:

Name	WLAN
Type	WiFi SSID
Traffic Mode	Tunnel to Wireless Controller
IP/Network Mask	172.20.150.17/255.255.255.0
DHCP Server	Enabled
SSID	wireless
Pre-shared Key	password

3. Select **OK**.

Create a Firewall Policy

1. Go to **Policy & Objects** > **Policy > IPv4** and select **Create New**.
2. Change the following settings:

Incoming Interface	access_point
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	HTTP HTTPS DNS
Action	ACCEPT
Enable NAT	Enabled
Logging Options	Log all Sessions

3. Select **OK**.
4. Go to **WiFi & Switch Controller > Managed Devices > Managed FortiAPs**. The Status icon now appears in green, showing that the FortiSwitch unit is online.

You have now finished creating a policy that matches scenario 7.

Using the CLI

1. Create the access_point VLAN.

```
config switch-controller vlan
   edit access_point
      set color 7
end
```

2. Assign the access_point VLAN to port 1.

```
config switch-controller managed-switch
   edit FS224D3W14000370
      config ports
         edit port1
            set vlan access_point
      end
end
```

3. Set the interface IP and enable CAPWAP.

```
config system interface
   edit access_point
      set ip 172.20.150.17
      set allowaccess capwap
end
```

4. Enable the FortiAP unit.

```
config wireless-controller wtp
```

```
   edit FAP11C3X13000412
      set admin enable
end
```

5. Create an SSID for the FortiAP unit.

```
config wireless-controller vap
   edit WLAN
      set ssid wireless
      set passphrase password
end
```

6. Configure the firewall policy.

```
config firewall policy
   edit 6
      set srcintf access_point
      set dstintf wan1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service HTTP HTTPS DNS
      set logtraffic all
      set nat enable
end
```

Chapter 21 - Security Profiles

This FortiOS Handbook chapter contains the following sections:

Security Profiles overview describes Security Profiles components and their relation to firewall policies, as well as SSL content scanning and inspection. We recommend starting with this section to become familiar with the different features in your FortiGate unit.

Client Reputation explains how to track client behavior and report on activities that you determine are risky or otherwise noteworthy.

AntiVirus explains how the FortiGate unit scans files for viruses and describes how to configure the antivirus options.

Email filter explains how the FortiGate unit filters email, describes how to configure the filtering options and the action to take with email detected as spam.

Intrusion protection explains basic Intrusion Protection System (IPS) concepts and how to configure IPS options; includes guidance and a detailed table for creating custom signatures as well as several examples.

Web filter and FortiGuard Web Filter The first of these sections describes basic web filtering concepts, the order in which the FortiGate unit performs web filtering, and configuration. The second section describes enhanced features of the subscription-based FortiGuard Web Filtering service and explains how to configure them. We recommend reading both sections if you are using FortiGuard Web Filtering because settings you configure in one feature may affect the other.

Data leak prevention describes the DLP features that allow you to prevent sensitive data from leaving your network and explains how to configure the DLP rules, compound rules, and sensors.

Application control describes how your FortiGate unit can detect and take action against network traffic based on the application generating the traffic.

Security Profiles overview

Ranging from the FortiGate®-30 series for small businesses to the FortiGate-5000 series for large enterprises, service providers and carriers, the FortiGate line combines a number of security features to protect your network from threats. As a whole, these features, when included in a single Fortinet security appliance, are referred to as Security Profiles. The Security Profiles features your FortiGate model includes are:

- AntiVirus
- Intrusion Prevention System (IPS)
- Web filtering
- E-mail filtering, including protection against spam and grayware
- Data Leak Prevention (DLP)
- Application Control
- ICAP

Firewall policies limit access, and while this and similar features are a vital part of securing your network, they are not covered in this document.

The following topics are included in this section:

- Traffic inspection
- Content inspection and filtering
- Security Profiles components
- Security Profiles/lists/sensors

Traffic inspection

When the FortiGate unit examines network traffic one packet at a time for IPS signatures, it is performing traffic analysis. This is unlike content analysis where the traffic is buffered until files, email messages, web pages, and other files are assembled and examined as a whole.

DoS policies use traffic analysis by keeping track of the type and quantity of packets, as well as their source and destination addresses.

Application control uses traffic analysis to determine which application generated the packet.

Although traffic inspection doesn't involve taking packets and assembling files they are carrying, the packets themselves can be split into fragments as they pass from network to network. These fragments are reassembled by the FortiGate unit before examination.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against content threats.

IPS signatures

IPS signatures can detect malicious network traffic. For example, the Code Red worm attacked a vulnerability in the Microsoft IIS web server. Your FortiGate's IPS system can detect traffic attempting to exploit this vulnerability. IPS may also detect when infected systems communicate with servers to receive instructions.

IPS recommendations

- Enable IPS scanning at the network edge for all services.
- Use FortiClient endpoint IPS scanning for protection against threats that get into your network.
- Subscribe to FortiGuard IPS Updates and configure your FortiGate unit to receive push updates. This will ensure you receive new IPS signatures as soon as they are available.
- Your FortiGate unit includes IPS signatures written to protect specific software titles from DoS attacks. Enable the signatures for the software you have installed and set the signature action to **Block**.
- You can view these signatures by going to **Security Profiles > Intrusion Protection** and selecting the **[View IPS Signatures]** link.
- Because it is critical to guard against attacks on services that you make available to the public, configure IPS signatures to block matching signatures. For example, if you have a web server, configure the action of web server signatures to **Block**.

Suspicious traffic attributes

Network traffic itself can be used as an attack vector or a means to probe a network before an attack. For example, SYN and FIN flags should never appear together in the same TCP packet. The SYN flag is used to initiate a TCP session while the FIN flag indicates the end of data transmission at the end of a TCP session.

The FortiGate unit has IPS signatures that recognize abnormal and suspicious traffic attributes. The SYN/FIN combination is one of the suspicious flag combinations detected in TCP traffic by the `TCP.BAD.FLAGS` signature.

The signatures that are created specifically to examine traffic options and settings, begin with the name of the traffic type they are associated with. For example, signatures created to examine TCP traffic have signature names starting with TCP.

Application control

While applications can often be blocked by the ports they use, application control allows convenient management of all supported applications, including those that do not use set ports.

Application control recommendations

- Some applications behave in an unusual manner in regards to application control. For more information, see "Application considerations".
- By default, application control allows the applications not specified in the application control list. For high security networks, you may want to change this behavior so that only the explicitly allowed applications are permitted.

Content inspection and filtering

When the FortiGate unit buffers the packets containing files, email messages, web pages, and other similar files for reassembly before examining them, it is performing content inspection. Traffic inspectionTraff, on the other hand, is accomplished by the FortiGate unit examining individual packets of network traffic as they are received.

No two networks are the same and few recommendations apply to all networks. This topic offers suggestions on how you can use the FortiGate unit to help secure your network against content threats. Be sure to understand the effects of the changes before using the suggestions.

AntiVirus

The FortiGate antivirus scanner can detect viruses and other malicious payloads used to infect machines. The FortiGate unit performs deep content inspection. To prevent attempts to disguise viruseAns, the antivirus scanner will reassemble fragmented files and uncompress content that has been compressed. Patented Compact Pattern Recognition Language (CPRL) allows further inspection for common patterns, increasing detection rates of virus variations in the future.

AntiVirus recommendations

- Enable antivirus scanning at the network edge for all services.
- Use FortiClient endpoint antivirus scanning for protection against threats that get into your network.
- Subscribe to FortiGuard AntiVirus Updates and configure your FortiGate unit to receive push updates. This will ensure you receive new antivirus signatures as soon as they are available.
- Enable the Extended Virus Database if your FortiGate unit supports it.
- Examine antivirus logs periodically. Take particular notice of repeated detections. For example, repeated virus detection in SMTP traffic could indicate a system on your network is infected and is attempting to contact other systems to spread the infection using a mass mailer.
- The **builtin-patterns** file filter list contains nearly 20 file patterns. Many of the represented files can be executed or opened with a double-click. If any of these file patterns are not received as a part of your normal traffic, blocking them may help protect your network. This also saves resources since files blocked in this way do not need to be scanned for viruses.
- To conserve system resources, avoid scanning email messages twice. Scan messages as they enter and leave your network or when clients send and retrieve them, rather than both.

FortiGuard Web Filtering

The web is the most popular part of the Internet and, as a consequence, virtually every computer connected to the Internet is able to communicate using port 80, HTTP. Botnet communications take advantage of this open port and use it to communicate with infected computers. FortiGuard Web Filtering can help stop infections from malware sites and help prevent communication if an infection occurs.

FortiGuard Web Filtering recommendations

- Enable FortiGuard Web Filtering at the network edge.
- Install the FortiClient application and use FortiGuard Web Filtering on any systems that bypass your FortiGate unit.
- Block categories such as Pornography, Malware, Spyware, and Phishing. These categories are more likely to be dangerous.
- In the email filter profile, enable **IP Address Check** in **FortiGuard Email Filtering**. Many IP addresses used in spam messages lead to malicious sites; checking them will protect your users and your network.

Email filter

Spam is a common means by which attacks are delivered. Users often open email attachments they should not, and infect their own machine. The FortiGate email filter can detect harmful spam and mark it, alerting the user to the potential danger.

Email filter recommendations

- Enable email filtering at the network edge for all types of email traffic.
- Use FortiClient endpoint scanning for protection against threats that get into your network.
- Subscribe to the FortiGuard AntiSpam Service.

DLP

Most security features on the FortiGate unit are designed to keep unwanted traffic out of your network while DLP can help you keep sensitive information from leaving your network. For example, credit card numbers and social security numbers can be detected by DLP sensors.

DLP recommendations

- Rules related to HTTP posts can be created, but if the requirement is to block all HTTP posts, a better solution is to use application control or the **HTTP POST Action** option in the web filter profile.
- While DLP can detect sensitive data, it is more efficient to block unnecessary communication channels than to use DLP to examine it. If you don't use instant messaging or peer-to-peer communication in your organization, for example, use application control to block them entirely.

Security Profiles components

AntiVirus

Your FortiGate unit stores a virus signature database that can identify more than 15,000 individual viruses. FortiGate models that support additional virus databases are able to identify hundreds of thousands of viruses. With a FortiGuard AntiVirus subscription, the signature databases are updated whenever a new threat is discovered.

AntiVirus also includes file filtering. When you specify files by type or by file name, the FortiGate unit will stop the matching files from reaching your users.

FortiGate units with a hard drive or configured to use a FortiAnalyzer unit can store infected and blocked files for that you can examine later.

Intrusion Protection System (IPS)

The FortiGate Intrusion Protection System (IPS) protects your network against hacking and other attempts to exploit vulnerabilities of your systems. More than 3,000 signatures are able to detect exploits against various operating systems, host types, protocols, and applications. These exploits can be stopped before they reach your internal network.

You can also write custom signatures, tailored to your network.

Web filtering

Web filtering includes a number of features you can use to protect or limit your users' activity on the web.

FortiGuard Web Filtering is a subscription service that allows you to limit access to web sites. More than 60 million web sites and two billion web pages are rated by category. You can choose to allow or block each of the 77 categories.

URL filtering can block your network users from access to URLs that you specify.

Web content filtering can restrict access to web pages based on words and phrases appearing on the web page itself. You can build lists of words and phrases, each with a score. When a web content list is selected in a web filter profile, you can specify a threshold. If a user attempts to load a web page and the score of the words on the page exceeds the threshold, the web page is blocked.

Email filtering

FortiGuard AntiSpam is a subscription service that includes an IP address black list, a URL black list, and an email checksum database. These resources are updated whenever new spam messages are received, so you do not need to maintain any lists or databases to ensure accurate spam detection.

You can use your own IP address lists and email address lists to allow or deny addresses, based on your own needs and circumstances.

Data Leak Prevention (DLP)

Data leak prevention allows you to define the format of sensitive data. The FortiGate unit can then monitor network traffic and stop sensitive information from leaving your network. Rules for U.S. social security numbers, Canadian social insurance numbers, as well as Visa, Mastercard, and American Express card numbers are included.

Application Control

Although you can block the use of some applications by blocking the ports they use for communications, many applications do not use standard ports to communicate. Application control can detect the network traffic of more than 1000 applications, improving your control over application communication.

ICAP

This module allows for the offloading of certain processes to a separate server so that your FortiGate firewall can optimize its resources and maintain the best level of performance possible.

Security Profiles/lists/sensors

A profile is a group of settings that you can apply to one or more firewall policies. Each Security Profile feature is enabled and configured in a profile, list, or sensor. These are then selected in a security policy and the settings apply to all traffic matching the policy. For example, if you create an antivirus profile that enables antivirus scanning of HTTP traffic, and select the antivirus profile in the security policy that allows your users to access the World Wide Web, all of their web browsing traffic will be scanned for viruses.

While you can apply more than one security profile to a firewall policy, it is not recommended that you use flow-based profiles and proxy-based profiles in the same firewall policy.

Because you can use profiles in more than one security policy, you can configure one profile for the traffic types handled by a set of firewall policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you

might configure two separate sets of profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

The Security Profiles include:

- Antivirus profile
- IPS sensor
- Web filter profile
- Email filter profile
- Data Leak Prevention profile
- Application Control list
- VoIP profile

Although they're called profiles, sensors, and lists, they're functionally equivalent. Each is used to configure how the feature works.

AntiVirus

This section describes how to configure the antivirus options. From an antivirus profile you can configure the FortiGate unit to apply antivirus protection to HTTP, FTP, IMAP, POP3, SMTP, and NNTP sessions. If your FortiGate unit supports SSL content scanning and inspection, you can also configure antivirus protection for HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.

In many cases you can just customize the default antivirus profile and apply it to the security policy that accepts the traffic to be virus scanned. You can also create custom antivirus profiles if want to apply different types of virus protection to different traffic.

The following topics are included in this section:

- Antivirus concepts
- Enabling AntiVirus scanning
- Testing your antivirus configuration
- Example Scenarios

Antivirus concepts

The word “antivirus” refers to a group of features that are designed to prevent unwanted and potentially malicious files from entering your network. These features all work in different ways, which include checking for a file size, name, or type, or for the presence of a virus or grayware signature.

The antivirus scanning routines your FortiGate unit uses are designed to share access to the network traffic. This way, each individual feature does not have to examine the network traffic as a separate operation, and the overhead is reduced significantly. For example, if you enable file filtering and virus scanning, the resources used to complete these tasks are only slightly greater than enabling virus scanning alone. Two features do not require twice the resources.

Antivirus scanning examines files for viruses, worms, trojans, and other malware. The antivirus scan engine has a database of virus signatures it uses to identify infections. If the scanner finds a signature in a file, it determines that the file is infected and takes the appropriate action.

Malware Threats

Viruses

Viruses are self replicating code that install copies of themselves into other programs, data files for boot sectors of storage devices. Virus can often carry a “payload” which performs some undesirable function. These functions can include but are not limited to:

- Stealing drive space
- Stealing cpu cycles
- Accessing private information
- Corrupting data

- Digital defacement or vandalism
- Spamming contact lists

Worms

A worm is a piece of standalone computer code that replicates itself in order to spread to other computers. It normally uses a computer network to spread itself, using security vulnerabilities on the target computer or network to propagate. Unlike a virus, it does not attach itself to an existing file. Even is there is no payload, worms consume resources such as bandwidth and storage space just through their act of replication.

Trojan horses

A Trojan horse, or Trojan is malware that is defined by its delivery method. Through the use of social engineering, or some other method, the code is installed on a system by a valid user of the system and like the original Trojan horse there is something more than advertised within the software. Trojans, unlike worms or viruses are generally non-self-replicating. The most common payload of a Trojan is the setting up of a “backdoor” control mechanism to the system that it is installed on.

Ransomware

Ransomware is a type of malware that, as the name implies, hold the system ransom until payment of some kind is made. It does this by restricting access to the legitimate owner of the system either by encrypting files or locking the system. Usually, a message of some kind is displayed with the demands. Upon payment a utility or key is sent to the user to unlock the system.

Scareware

Scareware comes in two main flavours; the first tries to convince the user that his computer is invected with some non-existent malware, scaring the user into purchasing the author’s virus removal utility. The utility is nonfunctional or some additional form of malware.

The second form tries to convince the user that the computer has been or is being used for an illegal act such as being part of a bot net or storing child pornography. Again, the objective is to scare the user into paying to cure something that is not really there.

Spyware

Spyware is used by its authors to collect information about the user and its computer without the users knowledge. The end result can be as benign as being better able to target adds, to as criminal as key loggers designed to record account ids and passwords of bank accounts and forward them off to the authors.

Adware

Adware is not malware per se. It is merely any software that produces advertisements in order to generate revenue for its author. While a lot of people find this inconvenient or irritating it is not malware. As such it is not blocked by the antivirus software for being malware. This doesn’t mean that software that has adware built into it will not be block if it does have malware in it.

Botnets

A botnet is a network of Internet connected computers that have been covertly usurped to forward transmissions to other computers on the Internet on behalf of a “master”. These transmission can be merely annoying such as spam or they can critically impact a target as when used to launch a Distributed Denial of Service attack.

Any such computer is referred to as a zombie - in effect, a computer "robot" or "bot" that serves the wishes of some master spam or virus originator. Most computers compromised in this way are home-based.

According to a report from Russian-based Kaspersky Labs, botnets -- not spam, viruses, or worms -- currently pose the biggest threat to the Internet. A report from Symantec came to a similar conclusion.

Phishing

Phishing is a social engineering technique that is used to obtain sensitive and confidential information by masquerading as a communication from a trusted entity such as a well known institution, company or website. Usually, the malware is not in the communication itself but in the links within the communication.

Grayware

Grayware programs are unsolicited software programs installed on computers, often without the user’s consent or knowledge. Grayware programs are generally considered an annoyance, but they can also cause system performance problems or be used for malicious purposes.

Scanning Modes

FortiOS has two different mode of scanning for malware. The reasons for the different modes are performance and granularity. In just about everything relating to security there is a constant balancing act going on. As you increase the level of security and comprehensiveness, there is by necessity a decrease in either convenience or performance, sometimes both. The increase in processing to scan for more threats requires more resources; resources that are a finite supply on the hardware. Granularity can sometimes be used to mitigate performance impact by scanning for a smaller subset of traffic but this is only recommended when that smaller subset of traffic is the only traffic going through the firewall.

If the the traffic on the device is slight then the impact on the performance will hardly be noticeable, but it the unit is working close to capacity in terms of traffic and there are a lot of files coming through then there might be a noticeable decline in the performance.

While both modes offer significant security, Proxy-based is weighted towards being more thorough and easily configurable, while Flow-based is designed to optimize performance.

Proxy

The most thorough scan requires that the FortiGate unit have the whole file for the scanning procedure. To achieve this, the antivirus proxy buffers the file as it arrives. Once the transmission is complete, the virus scanner examines the file. If no infection is present, it is sent to the destination. If an infection is present, a replacement message is set to the destination.

During the buffering and scanning procedure, the client must wait. With a default configuration, the file is released to the client only after it is scanned. You can enable client comforting in the Proxy Options profile to feed the client a trickle of data to prevent them from thinking the transfer is stalled, and possibly cancelling the download.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Archives can also be expanded and the contents scanned, even if archives are nested.

Since the FortiGate unit has a limited amount of memory, files larger than a certain size do not fit within the memory buffer. The default buffer size is 10 MB. You can use the uncompsizelimit CLI command to adjust the size of this memory buffer.

Files larger than the buffer are passed to the destination without scanning. You can use the **Oversize File/Email** setting to block files larger than the antivirus buffer if allowing files that are too large to be scanned is an unacceptable security risk.

Flow-based

If your FortiGate unit supports flow-based antivirus scanning, you can select it instead of proxy-based antivirus scanning. The way flow-based antivirus works changed significantly starting with firmware version 5.2. In fact, the new method of flow-based antivirus inspection is sometimes called "deep flow" inspection to differentiate it from the older method.

As packets of a file come into the FortiGate unit, a copy of the packet is cached locally before the packet is allowed to pass through to the recipient. When the last packet of the file arrives, it is also cached but put on hold. Now the entire cached file is delivered to the Antivirus engine for a full scanning, just as it would be if using the proxy-based method, using what ever antivirus database has been configured.

If the file is determined to be infected with malware, the last packet will be dropped and the session is reset. Without all of the packets the file cannot be built by the recipient. When download a file through an HTTP connection (or HTTPS is SSL scanning is enabled), the flow-based feature remembers the last virus result so any subsequent attempts to download the same file will be welcomed by an appropriate blocked message directly, without engaging in the effort of downloading the file.

By using the same engine as the proxy-based method the detection rate is the same for both methods. In terms of performance from the end user's stand point, the performance of the download will be a lot faster until the last packet and then there will be a slight delay for the scan, but after the determination is made only one packet has to be sent from the firewall to the recipient so the overall speed is faster than the proxy based method.

An additional advantage of the flow-based method is that the scanning process does not change the packets as they pass through the FortiGate unit, while proxy-based scanning can change packet details such as sequence numbers. The changes made by proxy-based scanning do not affect most networks.

Antivirus scanning order

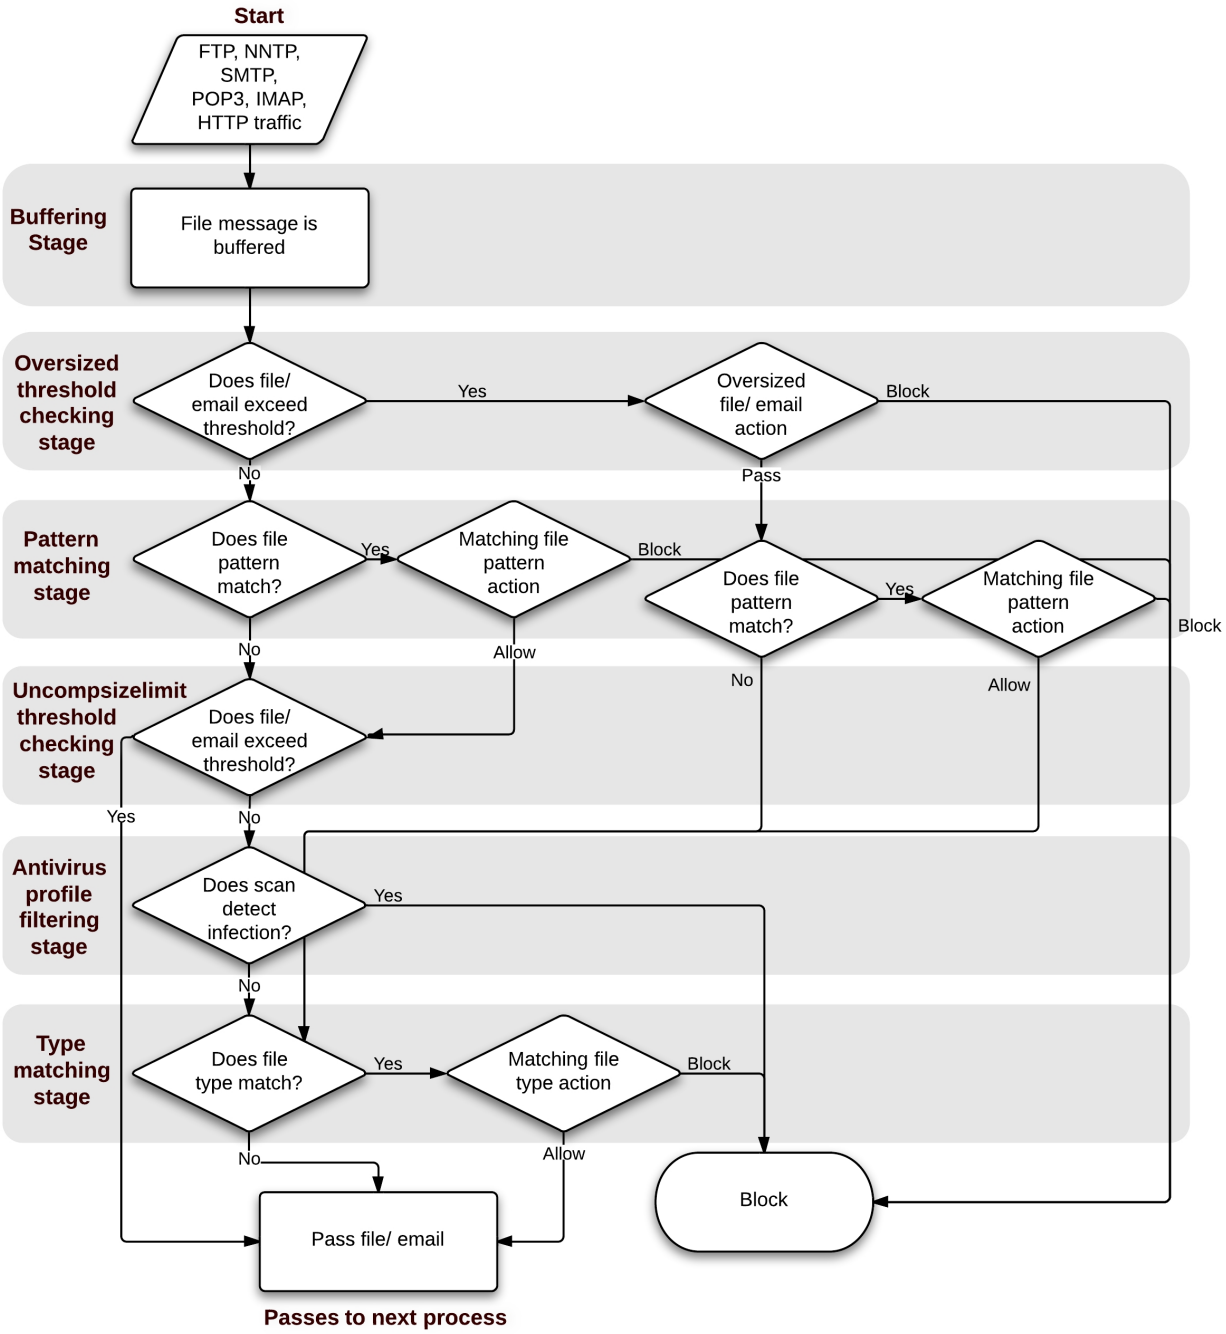
The antivirus scanning function includes various modules and engines that perform separate tasks.

Proxy-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using proxy-based scanning. The first check for oversized files/email is to determine whether the file exceeds the configured size threshold. The `uncompsizelimit` check is to determine if the file can be buffered for file type and antivirus scanning. If the file is too large for the buffer, it is allowed to pass without being scanned. For more information, see the `config antivirus service` command. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics if they are enabled.

File filtering includes file pattern and file type scans which are applied at different stages in the antivirus process.

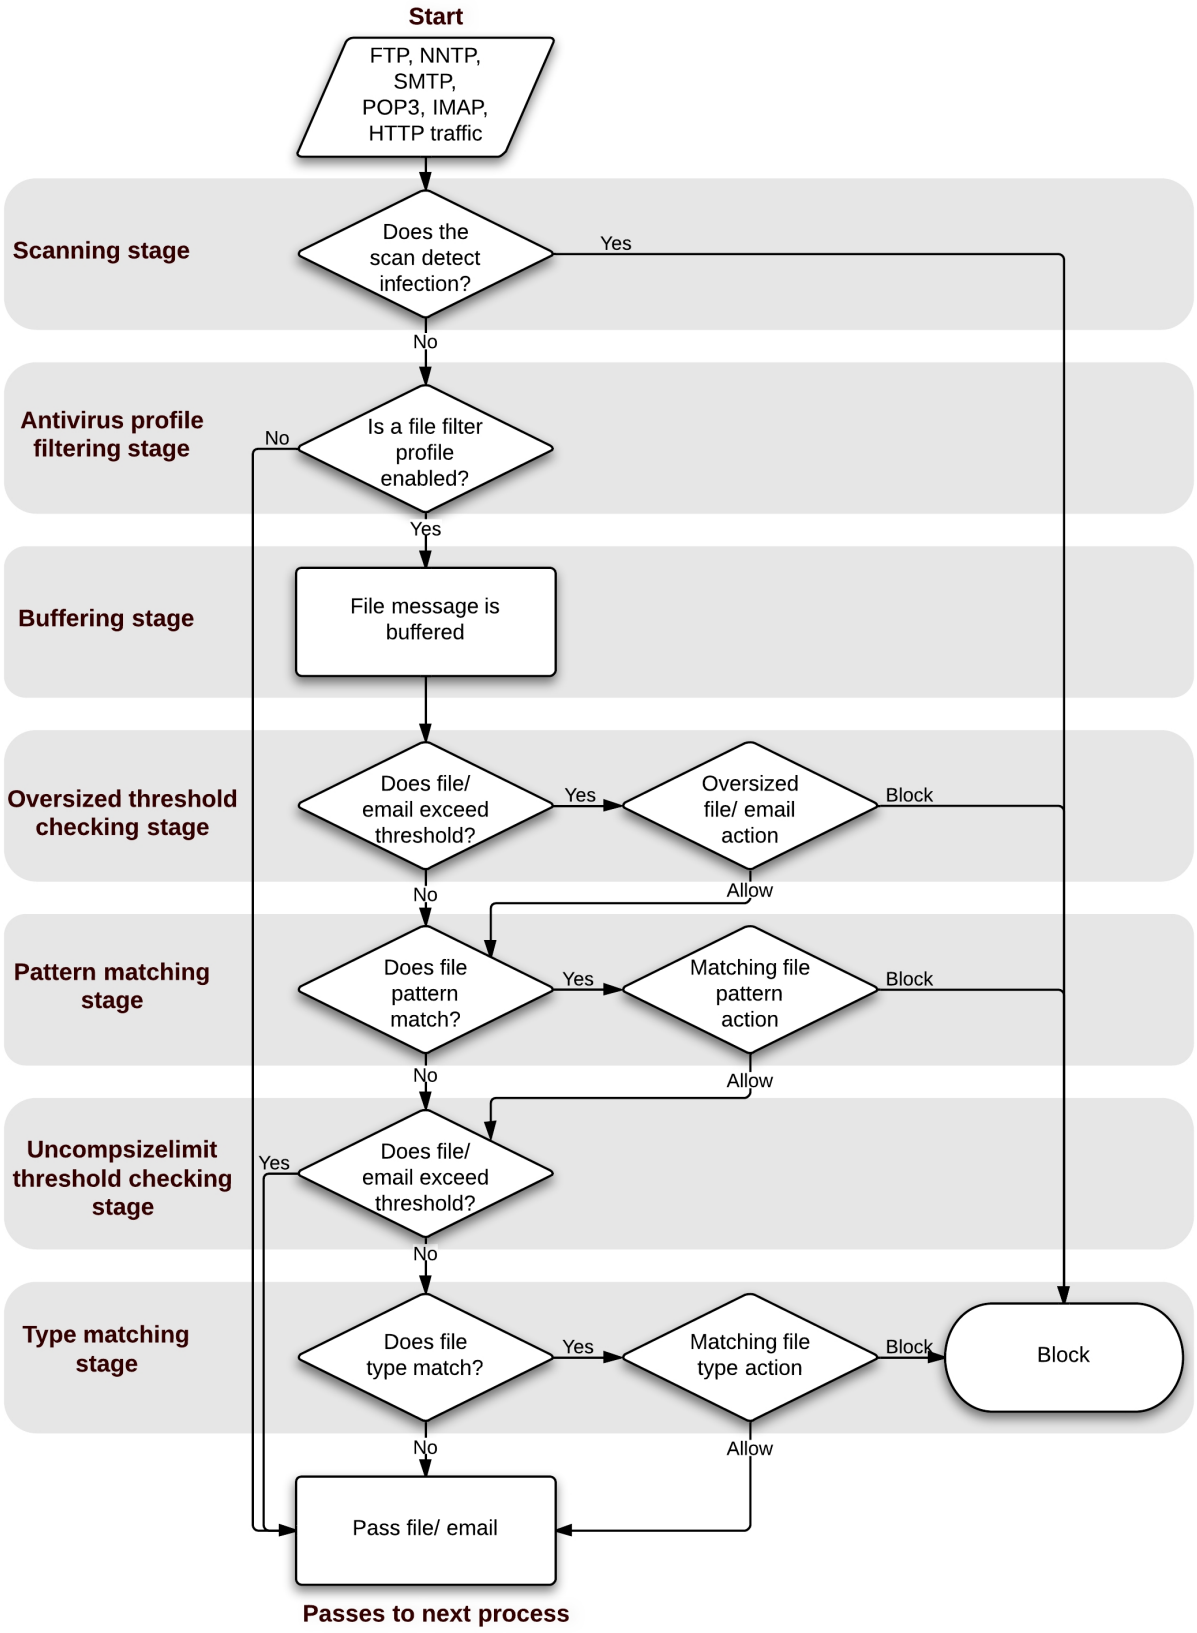
Antivirus scanning order when using the normal, extended, or extreme database



If a file fails any of the tasks of the antivirus scan, no further scans are performed. For example, if the file `fakefile.EXE` is recognized as a blocked file pattern, the FortiGate unit will send the end user a replacement message, and delete or quarantine the file. The unit will not perform virus scan, grayware, heuristics, and file type scans because the previous checks have already determined that the file is a threat and have dealt with it.

Flow-based antivirus scanning order

The following figure illustrates the antivirus scanning order when using flow-based scanning (i.e. the flow-based database). The antivirus scan takes place before any other antivirus-related scan. If file filter is not enabled, the file is not buffered. The antivirus scan includes scanning for viruses, as well as for grayware and heuristics if they are enabled.



Start
FTP, NNTP, SMTP, POP3, IMAP, HTTP traffic
Scanning stage
Does the scan detect infection?
Yes
No
Antivirus profile filtering stage
Is a file filter profile enabled?
No
Yes
Buffering stage
File message is buffered
Oversized threshold checking stage
Does file/ email exceed threshold?
Yes
Oversized file/ email action

No
Pattern matching stage
Does file pattern match?
Yes
Matching file pattern action
Block
Allow
No
Uncompsizelimit threshold checking stage
Does file/ email exceed threshold?
Yes
No
Type matching stage
Does file type match?
Yes
Matching file type action
Block
Block
No
Allow
Pass file/ email
Passes to next process

Antivirus databases

The antivirus scanning engine relies on a database of virus signatures to detail the unique attributes of each infection. The antivirus scan searches for these signatures, and when one is discovered, the FortiGate unit determines the file is infected and takes action.

All FortiGate units have the normal antivirus signature database but some models have additional databases you can select for use. Which you choose depends on your network and security needs.

Normal	Includes viruses currently spreading as determined by the FortiGuard Global Security Research Team. These viruses are the greatest threat. The Normal database is the default selection and it is available on every FortiGate unit.
Extended	Includes the normal database in addition to recent viruses that are no-longer active. These viruses may have been spreading within the last year but have since nearly or completely disappeared.
Extreme	Includes the extended database in addition to a large collection of 'zoo' viruses. These are viruses that have not spread in a long time and are largely dormant today. Some zoo viruses may rely on operating systems and hardware that are no longer widely used.

If your FortiGate unit supports extended, extreme, or flow-based virus database definitions, you can select the virus database most suited to your needs.

If you require the most comprehensive antivirus protection, enable the extended virus database. The additional coverage comes at a cost, however, because the extra processing requires additional resources.

To change the antivirus database

Use the CLI to run the following commands:

```
config antivirus settings
   set default-db extended
end
```

Antivirus techniques

The first three antivirus features work in sequence to efficiently scan incoming files and offer your network optimum antivirus protection. The first two features have specific functions, the third, heuristics, protects against new, or previously unknown virus threats.

To ensure that your system is providing the most protection available, all virus definitions and signatures are updated regularly through the FortiGuard antivirus services.

The Botnet protection looks for links to malware rather than malware itself.

Virus scan

If the file passes the file pattern scan, the FortiGate unit applies a virus scan to it. The virus definitions are kept up-to-date through the FortiGuard Distribution Network (FDN).

Grayware protection

If the file passes the virus scan, it can be checked for grayware.

Grayware scanning is an optional function and must be enabled in the CLI if it is to be scanned for along with other malware. Grayware cannot be scanned for on its own. While done as a separate step, antivirus scanning must be enabled as well.

To enable grayware detection enter the following in the CLI:

```
config antivirus settings
   set grayware enable
end
```

To disable grayware detection enter the following in the CLI:

```
config antivirus settings
   set grayware disable
end
```

Grayware signatures are kept up to date in the same manner as the antivirus definitions.

Heuristics

After an incoming file has passed the grayware scan, it is subjected to the heuristics scan. The FortiGate heuristic antivirus engine, if enabled, performs tests on the file to detect virus-like behavior or known virus indicators. In this way, heuristic scanning may detect new viruses, but may also produce some false positive results. You configure heuristics from the CLI.

To set heuristics, enter the following in the CLI:

```
config antivirus heuristic
   set mode {pass |block |disable}
end
```

- "`block`" enables heuristics and any files determined to be malware are blocked from entering the network.
- "`pass`" enables heuristics but any files determined to be malware are still allowed to pass through to the recipient.
- "`disable`" turns off heuristics.

FortiGuard Antivirus

The FortiGuard Antivirus services are included in the regular FortiGuard subscription and include automatic updates of antivirus engines and definitions as well as a DNS black list (DNSBL) through the FortiGuard Distribution Network (FDN).

Current information about your subscription and version numbers can be found at **System > Config > FortiGuard.** This page will also allow the configuration of connections to the FortiGuard Center and how often to check for updates to the antivirus files.

Botnet protection

Protection from having your system being controlled by a botnet is achieved by detecting and blocking connection attempts to known botnets. This feature also includes connections to known phishing sites. The FortiGuard IP Reputation Database (IRDB) continually updated with addresses of known command and control (C&C) sites that botnet clients attempt to connect to, as well as a database of phishing URLs. Access to this database is available to users through FortiCare support contracts purchased or renewed before October 1, 2016. After that date, users

will have to subscribe to the IRDB either through FortiGuard Mobility Security Service (FMSS) or the FortiGuard Enterprise Bundle.

To enable Botnet and phishing protection in an antivirus profile check the checkbox next to **Detect Connection to Botnet C&C Servers**.

The Botnet protection feature is available for both proxy and flow-based antivirus profiles.

Quarantine / Source IP ban

Starting in FortiOS 5.2, the quarantine, as a place where traffic content was held in storage where it couldn't interact with the network or system was removed, but the term quarantine was kept to describe keeping selected source IPs from interacting with the network and protected systems. This source IP ban is kept in the kernel rather than in any specific application engine and can be queried by APIs. The features that can use the APIs to access and use the banned source IP addresses are antivirus, DLP, DoS and IPS. Both IPv4 and IPv6 version are included in this feature.

To configure the antivirus profile to add the source IP address of an infected file to the quarantine or list of banned source IP addresses edit the Antivirus profile, in the CLI. as follows:

```
config antivirus profile
   edit <name of profile>
      config nac-quar
         set infected quar-src-ip
         set expiry 5m
      end
```

If the `quar-src-ip` action is used, the additional variable of expiry time will become available. This variable determines for how long the source IP adddress will be blocked. In the CLI the option is called `expiry` and the duration is in the format `<###d##h##m>`. The maximum days value is 364. The maximum hour value is 23 and the maximum minute value is 59. The default is 5 minutes.

FortiGuard Sandbox

Not every piece of malware has a signature yet. This is especially true of new malware and new variations on existing malware. FortiOS can upload suspicious files to FortiGuard Sandbox where the file will be executed and the resulting behavior analyzed for risk. If the file exhibits risky behavior or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database. The next time your FortiGate unit updates its antivirus database it will have the new signature.

A file is considered suspicious if it does not contain a known virus and if it has some suspicious characteristics. The suspicious characteristics can change depending on the current threat climate and other factors. Fortinet optimizes how files are uploaded as required.

To configure an Antivirus profile to enable the use of the FortiGuard Sandbox check the checkbox next to **Send Files to FortiGuard Sandbox for Inspection (Requires FortiCloud account)**.

Sending files to the FortiGuard Sandbox does not block files that it uploads. Instead they are used to improve how quickly new threats can be discovered and signatures created for them and added to the FortiGuard antivirus database.

The Advanced Threat Protection dashboard widget shows the number of files that your FortiGate unit has uploaded or submitted to FortiGuard Sandbox.

Client Comforting

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit scans it. If no infection is found, the file is sent along to the client. The client initiates the file transfer and nothing happens until the FortiGate finds the file clean, and releases it. Users can be impatient, and if the file is large or the download slow, they may cancel the download, not realizing that the transfer is in progress.

The client comforting feature solves this problem by allowing a trickle of data to flow to the client so they can see the file is being transferred. The default client comforting transfer rate sends one byte of data to the client every ten seconds. This slow transfer continues while the FortiGate unit buffers the file and scans it. If the file is infection-free, it is released and the client will receive the remainder of the transfer at full speed. If the file is infected, the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Enable and configure client comforting

1. Go to **Policy & Objects> Policy > Proxy Options**.
2. Select a Proxy Options profile and choose **Edit**, or select **Create New** to make a new one.
3. Scroll down to the **Common Options** section and check the box next to **Comfort Clients**. This will set the option on all of the applicable protocols. The ability to set this feature on a protocol by protocol basis exists in the CLI
4. Select **OK or Apply** to save the changes.
5. Select this Proxy Options profile in any security policy for it to take effect on all traffic handled by the policy.

The default values for Interval and Amount are 10 and 1, respectively. This means that when client comforting takes effect, 1 byte of the file is sent to the client every 10 seconds. You can change these values to vary the amount and frequency of the data transferred by client comforting.

Oversized files and emails

Downloaded files can range from a few Kilobytes to multiple Gigabytes. The problem lies in that a FortiGate doesn't have the memory to allow for a large number of people downloading large files. Image the memory required for a team of developers to all download the latest Linux OS distribution at once, in addition to the normal requirements of the firewall. Everything would come to a grinding halt the FortiGate tried to store each of those Gibabyte+ files in memory. To give you some piece of mind, the chances of malware being in a large file like those is much smaller than in a smaller single Megabyte file, so the threat is somewhat limited, but you will probably want to use your computers antivirus software to scan those large files after they have been downloaded.

Therefore a threshold must be set to prevent the resources of the system from becoming overloaded. By default the threshold is 10 MB. Any files larger than the threshold will not be scanned for malware. With a maximum file size threshold in place, it must now be determined what is to be done with the files that are larger than threshold. There are only 2 choices; either the file is passed through without being scanned for malware or the file is blocked. The default action for oversized files is to pass them through.

If you wish to block the downloading of files over the threshold, this can be set within the Proxy Option profile found at **Policy & Objects > Policy > Proxy Options**, under **Common Options**.

Check Block Oversized File/Email

This will reveal an additional option, Threshold (MB). The threshold of the files is set based upon the protocol being used to transfer the file. In the CLI and configuration file, the threshold variable is found in each of the protocol sections within the profile. Changing the value in this field will change the `oversize-limit` value for all of the protocols.

If you wish to change the oversize-limit value on all of the protocols covered in a Proxy Option profile you have two options.

1. You can go into the CLI and change the value manually within each of the protocol sections.
2. You can use the GUI to temporarily block oversized files, and when configuring it change the threshold to the new value that you want. Apply this setting. Then go back to the profile and turn off the block setting. If you now go into the CLI you will find that the configuration file has retained the new oversize-limit value.

The settings can be found in the CLI by going to:

```
config firewall profile-protocol-options
   edit <the name of the profile>
```

Archive scan depth

The antivirus scanner will open archives and scan the files inside. Archives within other archives, or nested archives, are also scanned to a default depth of twelve nestings. You can adjust the number of nested archives to which the FortiGate unit will scan with the uncompressed-nest-limit CLI command. Further, the limit is configured separately for each traffic type.

Configuring archive scan depth

For example, this CLI command sets the archive scan depth for SMTP traffic to 5. That is, archives within archives will be scanned five levels deep.

config firewall profile-protocol-options

```
edit "default"
   config http
      set uncompressed-nest-limit 5
   end
```

You can set the nesting limit from 2 to 100.

Scan buffer size

When checking files for viruses, there is a maximum file size that can be buffered. Files larger than this size are passed without scanning. The default size for all FortiGate models is 10 megabytes.

Archived files are extracted and email attachments are decoded before the FortiGate unit determines if they can fit in the scan buffer. For example, a 7 megabyte ZIP file containing a 12 megabyte EXE file will be passed

without scanning with the default buffer size. Although the archive would fit within the buffer, the uncompressed file size will not.

Configuring the uncompression buffer

In this example, the `uncompressed-oversize-limit` CLI command is used to change the scan buffer size to 20 megabytes for files found in HTTP traffic:

config firewall profile-protocol-options

```
edit "default"
   config http
      set uncompressed-oversize-limit 20
   end
```

The maximum buffer size varies by model. Enter `set uncompressed-oversize-limit ?` to display the buffer size range for your FortiGate unit.

Windows file sharing (CIFS)

FortiOS supports virus scanning of Windows file sharing traffic. This includes CIFS, SMB, and SAMBA traffic. This feature is applied by enabling SMB scanning in an antivirus profile and then adding this profile to a security policy that accepts CIFS traffic. CIFS virus scanning is available only through flow-based antivirus scanning.

FortiOS flow-based virus scanning can detect the same number of viruses in CIFS/SMB/SAMBA traffic as it can for all supported content protocols.

Note the following about CFIS/SMB/SAMBA virus scanning:

- Some newer version of SAMBA clients and SMB2 can spread one file across multiple sessions, preventing some viruses from being detected if this occurs.
- Enabling CIFS/SMB/SAMBA virus scanning can affect FortiGate performance.
- SMB2 is a new version of SMB that was first partially implemented in Windows Vista.
- Currently SMB2 is supported by Windows Vista or later, and partly supported by Samba 3.5 and fully support by Samba 3.6.
- The latest version of SMB2.2 will be introduced with Windows 8.
- Most clients still use SMB as default setting.

Configuring CIFS/SMB/SAMBA virus scanning

Use the following command to enable CIFS/SMB/SAMBA virus scanning in an antivirus profile:

```
config antivirus profile
   edit <smb-profile>
      config smb
         set options scan
      end
```

Then add this antivirus profile to a security policy that accepts the traffic to be virus scanned. In the security policy the service can be set to ANY, SAMBA, or SMB.

```
config firewall policy
   edit 0
      set service ANY
      ...
      set utm-status enable
      set av-profile <smb-profile>
```

```
end
```

Enabling AntiVirus scanning

Antivirus scanning is configured in an antivirus profile, but it is enabled in a firewall policy. Once the use of an antivirus profile is enabled and selected in one or more firewall policies, all the traffic controlled by those firewall policies will be scanned according to the settings in that profile.

In the Feature section found by going to **System > Config > Features,** you can enable or disable 2 aspects of the Antivirus Profile.

1. Antivirus will determine if the option to use Antivirus profiles is available.
2. Multiple Security Profiles will determine if you can configure any Antivirus profiles beyond the default profile.

The **Feature** section can sometimes be misunderstood as to its actual effect. The enabling or disabling of a feature in this section refers to its visibility within the GUI, not whether or not the feature's functionality will work. If you were to disable the Antivirus Profile feature it would disappear from the GUI but not the CLI and configuration file. Since the functionality of the FortiGate unit is based on the contents of the config file any profile referred to by the policy in the configuration will be acted upon. The Feature section is primarily for keeping the GUI clean and uncluttered by features that are not being used by the administrators.

As the use of antivirus these days is practically a minimum standard for security protection the question left to decide is whether or not you wish to use multiple profiles in your configuration.

Antivirus profiles

From **Security Profiles > Antivirus** you can edit existing profiles or create and configure new antivirus profiles that can then be applied to firewall policies. A profile is specific configuration information that defines how the traffic within a firewall policy is examined and what action may be taken based on the examination.

You can create multiple antivirus profiles for different antivirus scanning requirements. For example, you create an antivirus profile that specifies only virus scanning for POP3 which you then apply to the out-going firewall policy that is designed for users getting their email from the mail server. You can also choose specific protocols, such as HTTP, that will be scanned and if blocked, archived by the unit. This option is available only in the CLI.

Whether the mode of the antivirus detection is proxy-based or flow-based is also set within the profile.

Enable Antivirus steps - GUI based

1. Go to **Security Profiles > AntiVirus**.
2. Choose whether you want to edit an exiting profile or create a new one.
   - The default profile will be the one displayed by default.
   - If you are going to edit an existing profile, selecting it can be done by either using the drop down menu in the upper right hand corner of the window or by selecting the List icon (the furthest right of the 3 icons in the upper right of the window, if resembles a page with some lines on it), and then selecting the profile you want to edit from the list.
   - If you need to create a new profile you can either select the Create New icon (a plus sign within a circle) or select the List icon and then select the Create New link in the upper left of the window that appears.
3. If you are creating a new profile, write a name for it in the Name field.
4. Add or edit the Comments fields to more clearly describe the function.
5. Select the Inspection Mode.

6. For the Detect Viruses field, select either Block to prevent infected files from passing throughout the FortiGate or Monitor to allow infected files to pass through the FortiGate but to record instances of infection.
7. If you have a FortiCloud account, you can select **Send Files to FortiGuard Sandbox for Inspection (Requires FortiCloud account)**
   - **You can select whether to send All Files** to the Sandbox or **Suspicious Files Only.**
8. If you wish to use the Botnet feature, you can select Detect Connections to Botnet C&C Servers
   - Just like with the viruses, you can select whether to Block or Monitor the files that contain botnet or phishing connections.
9. Select **OK** or **Apply**.
10. Add the Antivirus profile to a firewall security policy.

Enable Antivirus steps - CLI based

You need to configure the scan option for each type of traffic you want scanned.

1. Configure the Antivirus profile

```
config antivirus profile
   edit "default"
      set comment "scan and delete virus"
      set replacemsg-group ''
      set scan-botnet-connections block
      set ftgd-analytics suspicious
      config http
         set options scan
         end
      config ftp
         set options scan
         end
      config imap
         set options scan
         end
      config pop3
         set options scan
         end
      config smtp
         set options scan
         end
      config nntp
         set options scan
         end
      config smb
         set options scan
         end
      end
```

2. Add the Antivirus profile to the Fortigate firewall security policy. When using the CLI, you will need to know the policy ID number.

```
config firewall policy
   edit <policy ID number>
      set av-profile default
      set profile-protocol-options default
      end
```

Testing your antivirus configuration

You have configured your FortiGate unit to stop viruses, but you'd like to confirm your settings are correct. Even if you have a real virus, it would be dangerous to use for this purpose. An incorrect configuration will allow the virus to infect your network.

To solve this problem, the European Institute of Computer Anti-virus Research has developed a test file that allows you to test your antivirus configuration. The EICAR test file is not a virus. It can not infect computers, nor can it spread or cause any damage. It's a very small file that contains a sequence of characters. Your FortiGate unit recognizes the EICAR test file as a virus so you can safely test your FortiGate unit antivirus configuration.

Go to http://www.fortiguard.com/antivirus/eicartest.html to download the test file (eicar.com) or the test file in a ZIP archive (eicar.zip).

If the antivirus profile applied to the security policy that allows you access to the Web is configured to scan HTTP traffic for viruses, any attempt to download the test file will be blocked. This indicates that you are protected.

Example Scenarios

The following examples provide a sample antivirus configuration scenarios.

Configuring simple default antivirus profile

The Antivirus function is so straight forward and widely used that many users just create one default profile and use that on all of the applicable firewall policies. If performance is not a real concern and the unit's resources are not being stretched, it is perfectly reasonable to create one profile that covers the range of uses found in your environment. This example is one possible default configuration.

Context:

- This is an edited default profile and will be used on all security policies
- It will need to scan for malware on all available protocols.
- Malware, botnets, and grayware should be blocked
- The inspection method should be flow-based
- A current FortiCloud account is available

Creating the profile - GUI

1. In the following fields, enter the indicated values or selections:

Name	default
Comments	Scans all traffic from Internet for malware
Inspection Mode	Flow-based
Detect Virus	Block
Send Files to FortiGuard Sandbox for Inspection	checked

• **Suspicious Files Only**	checked
Detect Connections to Botnet C&C Servers	checked
• **Block**	checked

2. Check the appropriate protocols:

Protocol	Virus Scan and Block
HTTP	checked
SMTP	checked
POP3	checked
IMAP	checked
MAPI	checked
FTP	checked
NNTP	checked

3. Select **Apply**.
4. Enable grayware scanning

```
config antivirus settings
   set grayware enable
   end
```

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
   - SSH through a terminal emulator
   - CLI Console widget
   - FortiExplorer's CLI mode
2. Enter the following commands:

```
config antivirus profile
   edit default
      set comment "scan and delete virus"
      set inspection-mode flow-based
      set scan-botnet-connections block
      set ftgd-analytics suspicious
      config http
         set options scan
         end
      config ftp
         set options scan
         end
      config imap
         set options scan
         end
```

```
config pop3
   set options scan
   end
config smtp
   set options scan
   end
config nntp
   set options scan
   end
config smb
   set options scan
   end
end
```

3. Enable grayware scanning

```
config antivirus settings
   set grayware enable
   end
```

Setting up a basic proxy-based Antivirus profile for email traffic

Small offices, whether they are small companies, home offices, or satellite offices, often have very simple needs. This example details how to enable antivirus protection on a FortiGate unit located in a satellite office.

Context:

- The satellite office does not have an internal email server. To send and retrieve email, the employees connect to an external mail server.
- There is a specific firewall security profile that handles the email traffic from the Internet to the mail server. The only traffic on this policy will be POP3 and IMAP and SMTP
- The company policy is to block viruses and connections to botnets.
- The FortiGate unit is a small model and the Internet bandwidth is limited so the policy is to not submit files to the FortiGuard Sandbox.

Creating the profile - GUI

1. In the following fields, enter the indicated values or selections:

Name	email-av
Comments	Scans email traffic from Internet for malware
Inspection Mode	Proxy
Detect Virus	Block
Send Files to FortiGuard Sandbox for Inspection	checked
• **Suspicious Files Only**	checked
Detect Connections to Bot-net C&C Servers	checked
• **Block**	checked

2. Check the appropriate protocols:

Protocol	Virus Scan and Block
HTTP	checked
SMTP	checked
POP3	checked
IMAP	checked
MAPI	checked
FTP	checked
NNTP	checked

3. Select **Apply**.

Creating the profile - CLI

1. Enter the CLI by one of the following methods:
   - SSH through a terminal emulator
   - CLI Console widget
   - FortiExplorer's CLI mode
2. Enter the following commands:

```
Config antivirus profile
   edit "email-av"
      set comment "Scans email traffic from Internet for malware"
      set inspection-mode proxy
      config imap
         set options scan
         end
      config pop3
         set options scan
         end
      config smtp
         set options scan
         end
      end
```

Adding the profile to a policy

In this scenario the following assumptions will be made:

- The policy that the profile is going to be added to is an IPv4 policy.
- The ID number of the policy is 11.
- The Antivirus profile being added will be the "default" profile
- The SSL/SSH Inspection profile used will be the "default" profile

Adding the profile - GUI

1. Go to **Policy & Objects > Policy > IPv4**.
2. Use your preferred method of finding a policy.
   - If the ID column is available you can use that.
   - You can also choose based on your knowledge of the parameters of the policy
   - Select the policy with ID value of 11
3. In the Edit Policy window, go to the Security Profiles section
4. Turn ON AntiVirus, and in the drop down menu for the field, select default
5. If the AntiVirus profile is proxy-based the Proxy Options field and drop down menu will be revealed.
6. The SSL/SSH Inspection field will automatically be set to ON and one of the profiles will need to be selected from the drop down menu. In this case default is selected.
7. The log options will depend on your requirements and resources but to verify that everything is working properly, it is a good idea to turn ON logging of All Sessions after setting up a new profile and after giving some time for logs to accumulate
8. Turn on Antivirus.
9. Select an antivirus profile.
10. Select **OK** to save the security policy.

Adding the profile - CLI

To select the antivirus profile in a security policy — CLI

```
config firewall policy
   edit 11
      set utm-status enable
      set profile-protocol-options default
      set av-profile basic_antivirus
   end
```

Block files larger than 8 MB

Set proxy options profile to block files larger than 8 MB

1. Go to **Policy & Objects > Policy > Proxy Options**.
2. Edit the default or select Create New to add a new one.
3. Scroll down to the common Options Section and place a check in the box next to BlockOversized File/Email
4. The sub line Threshold (MB) will appear with a value field. Enter 8.
5. Select **OK** or **Apply**.

The proxy options profile is configured, but to block files, you must select it in the firewall policies handling the traffic that contains the files you want blocked.

To select the Proxy Options profile in a security policy

1. Go to **Policy & Objects > Policy > IPv4** (or **IPv6**, depending).
2. Edit or create a security policy.

3. Select a proxy-based security profile. You will know that there is a proxy component to the Security Profile because when a Security Profile is Proxy based the Proxy Options field will be visible (for example, select an Antivirus profile that includes proxy scanning).
4. Beside Proxy Options select the name of the MTU proxy options protocol.
5. Select **OK** to save the security policy.
6. Once you complete these steps, any files in the traffic subject to Security Profile scanning handled by this policy that are larger than 8MB will be blocked. If you have multiple firewall policies, examine each to determine if you want to apply similar file blocking the them as well.

Web filter

This section describes FortiGate web filtering for HTTP traffic. The three main parts of the web filtering function, the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service interact with each other to provide maximum control over what the Internet user can view as well as protection to your network from many Internet content threats. Web Content Filter blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic.

The following topics are included in this section:

- Web filter concepts
- Inspections Modes
- FortiGuard Web Filtering Service
- Overriding FortiGuard website categorization
- SafeSearch
- YouTube Education Filter
- Static URL Filter
- Web content filter
- Advanced web filter configurations
- Configuring Web Filter Profiles
- Web filtering example

Web filter concepts

Web filtering is a means of controlling the content that an Internet user is able to view. With the popularity of web applications, the need to monitor and control web access is becoming a key component of secure content management systems that employ antivirus, web filtering, and messaging security. Important reasons for controlling web content include:

- lost productivity because employees are accessing the web for non-business reasons
- network congestion — when valuable bandwidth is used for non-business purposes, legitimate business applications suffer
- loss or exposure of confidential information through chat sites, non-approved email systems, instant messaging, and peer-to-peer file sharing
- increased exposure to web-based threats as employees surf non-business-related web sites
- legal liability when employees access/download inappropriate and offensive material
- copyright infringement caused by employees downloading and/or distributing copyrighted material.

As the number and severity of threats increase on the World Wide Web, the risk potential increases within a company's network as well. Casual non-business related web surfing has caused many businesses countless hours of legal litigation as hostile environments have been created by employees who download and view offensive content. Web-based attacks and threats are also becoming increasingly sophisticated. Threats and web-based applications that cause additional problems for corporations include:

- spyware/grayware
- phishing

- pharming
- instant messaging
- peer-to-peer file sharing
- streaming media
- blended network attacks.

Spyware, also known as grayware, is a type of computer program that attaches itself to a user's operating system. It does this without the user's consent or knowledge. It usually ends up on a computer because of something the user does such as clicking on a button in a pop-up window. Spyware can track the user's Internet usage, cause unwanted pop-up windows, and even direct the user to a host web site. For further information, visit the FortiGuard Center.

Some of the most common ways of grayware infection include:

- downloading shareware, freeware, or other forms of file-sharing services
- clicking on pop-up advertising
- visiting legitimate web sites infected with grayware.

Phishing is the term used to describe attacks that use web technology to trick users into revealing personal or financial information. Phishing attacks use web sites and email that claim to be from legitimate financial institutions to trick the viewer into believing that they are legitimate. Although phishing is initiated by spam email, getting the user to access the attacker's web site is always the next step.

Pharming is a next generation threat that is designed to identify and extract financial, and other key pieces of information for identity theft. Pharming is much more dangerous than phishing because it is designed to be completely hidden from the end user. Unlike phishing attacks that send out spam email requiring the user to click to a fraudulent URL, pharming attacks require no action from the user outside of their regular web surfing activities. Pharming attacks succeed by redirecting users from legitimate web sites to similar fraudulent web sites that have been created to look and feel like the authentic web site.

Instant messaging presents a number of problems. Instant messaging can be used to infect computers with spyware and viruses. Phishing attacks can be made using instant messaging. There is also a danger that employees may use instant messaging to release sensitive information to an outsider.

Peer-to-peer (P2P) networks are used for file sharing. Such files may contain viruses. Peer-to-peer applications take up valuable network resources and may lower employee productivity but also have legal implications with the downloading of copyrighted or sensitive company material.

Streaming media is a method of delivering multimedia, usually in the form of audio or video to Internet users. Viewing streaming media impacts legitimate business by using valuable bandwidth.

Blended network threats are rising and the sophistication of network threats is increasing with each new attack. Attackers learn from each previous successful attack and enhance and update attack code to become more dangerous and fast spreading. Blended attacks use a combination of methods to spread and cause damage. Using virus or network worm techniques combined with known system vulnerabilities, blended threats can quickly spread through email, web sites, and Trojan applications. Examples of blended threats include Nimda, Code Red, Slammer, and Blaster. Blended attacks can be designed to perform different types of attacks, which include disrupting network services, destroying or stealing information, and installing stealthy backdoor applications to grant remote access.

Different ways of controlling access

The methods available for monitoring and controlling Internet access range from manual and educational methods to fully automated systems designed to scan, inspect, rate and control web activity.

Common web access control mechanisms include:

- establishing and implementing a well-written usage policy in the organization on proper Internet, email, and computer conduct
- installing monitoring tools that record and report on Internet usage
- implementing policy-based tools that capture, rate, and block URLs.

The final method is the focus of this topic. The following information shows how the filters interact and how to use them to your advantage.

Order of web filtering

The FortiGate unit applies web filters in a specific order:

1. URL filter
2. FortiGuard Web Filter
3. web content filter
4. web script filter
5. antivirus scanning.

If you have blocked a FortiGuard Web Filter category but want certain users to have access to URLs within that pattern, you can use the **Override** within the FortiGuard Web Filter. This will allow you to specify which users have access to which blocked URLs and how long they have that access. For example, if you want a user to be able to access www.example.com for one hour, you can use the override to set up the exemption. Any user listed in an override must fill out an online authentication form that is presented when they try to access a blocked URL before the FortiGate unit will grant access to it. For more information, see “FortiGuard Web Filter”.

Inspection Modes

Proxy

Proxy-based inspection involves buffering the traffic and examining it as a whole before determining an action. The process of having the whole of the data to analyze allow this process to include more points of data to analyze than the flow-based or DNS methods.

The advantage of a proxy-based method is that the inspection can be more thorough than the other methods, resulting in fewer false positive or negative results in the analysis of the data.

Flow-based

The Flow-based inspection method examines the file as it passes through the FortiGate unit without any buffering. As each packet of the traffic arrives it is processed and forwarded without waiting for the complete file or web page, etc.

The advantage of the flow-based method is that the user sees a faster response time for HTTP requests and there is less chance of a time-out error due to the server at the other end responding slowly.

The disadvantages of this method are that there is a higher probability of a false positive or negative in the analysis of the data and that a number of points of analysis that can be used in the proxy-based method are not available in the flow-based inspection method. There is also fewer actions available to choose from based on the categorization of the website by FortiGuard services.

DNS

The DNS inspection method uses the same categories as the FortiGuard Service. It is lightweight in terms of resource usage because it doesn't involve any proxy-based or flow-based inspection.

A DNS request is typically the first part of any new session to a new website. This inspection method takes advantage of that and places the results of the categorization of websites right on the FortiGuard DNS servers. When the FortiGate resolves a URL, in addition to the IP address of the website it also receives a domain rating.

In the same way that the flow-based inspection method had fewer filters and points of analysis than the proxy-based inspection method, DNS has fewer settings still. All of its inspection is based on the IP address, the domain name and the rating provided by the FortiGuard DNS server.

If the DNS mode is chosen, the additional setting of a DNS action must be chosen. The options are:

- Block - The traffic will be blocked and the session dropped.
- Redirect - The session will be redirected to a message page indicating to the user what is happening.

FortiGuard Web Filtering Service

FortiGuard Web Filter is a managed web filtering solution available by subscription from Fortinet. FortiGuard Web Filter enhances the web filtering features supplied with your FortiGate unit by sorting billions of web pages into a wide range of categories users can allow or block. The FortiGate unit accesses the nearest FortiGuard Web Filter Service Point to determine the category of a requested web page, and then applies the security policy configured for that user or interface.

FortiGuard Web Filter includes over 45 million individual ratings of web sites that apply to more than two billion pages. Pages are sorted and rated into several dozen categories administrators can allow or block. Categories may be added or updated as the Internet evolves. To make configuration simpler, you can also choose to allow or block entire groups of categories. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

FortiGuard Web Filter ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. Users can notify the FortiGuard Web Filter Service Points if they feel a web page is not categorized correctly, so that the service can update the categories in a timely fashion.

Before you begin to use the FortiGuard Web Filter options you should verify that you have a valid subscription to the service for your FortiGate firewall.

FortiGuard Web Filter and your FortiGate unit

When FortiGuard Web Filter is enabled in a web filter profile, the setting is applied to all firewall policies that use this profile. When a request for a web page appears in traffic controlled by one of these firewall policies, the URL is sent to the nearest FortiGuard server. The URL category is returned. If the category is blocked, the FortiGate unit provides a replacement message in place of the requested page. If the category is not blocked, the page request is sent to the requested URL as normal.

FortiGuard Web Filter Actions

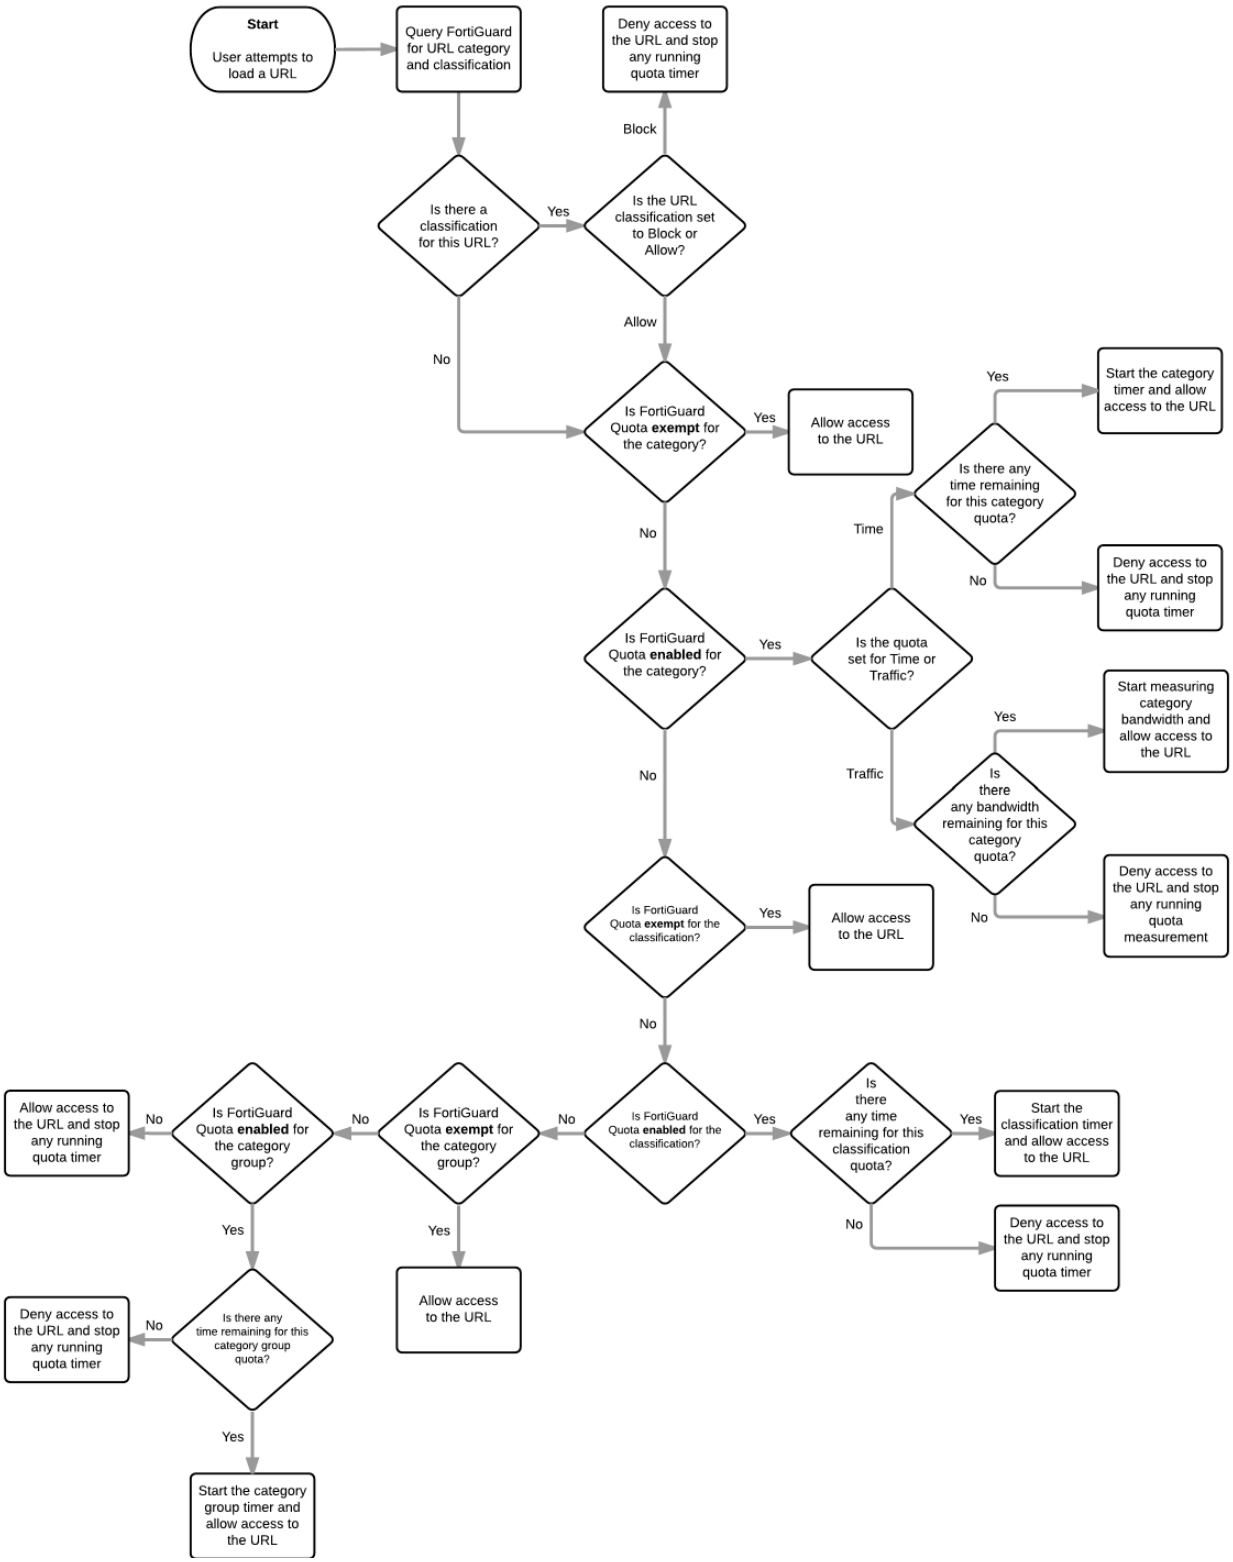
The Possible Actions are:

- **Allow** permits access to the sites within the category.
- **Monitor** permits and logs access to sites in the category. You may also enable user quotas when enabling the monitor action.
- **Warning** presents the user with a message, allowing them to continue if they choose.
- **Authenticate** requires a user authenticate with the FortiGate unit before being allowed access to the category or category group.
- **Block** prevents access to sites within the category. Users attempting to access a blocked site will receive a replacement message explaining that access to the site is blocked.

The choices of actions available will depend on the mode of inspection.

- Proxy - Allow, Block, Monitor, Warning, Authenticate & Disable.
- Flow-based - Allow, Block & Monitor.
- DNS - Allow, Block & Monitor.

Webfiltering flowchart



FortiGuard Web Filter usage quotas

In addition to using category and classification blocks and overrides to limit user access to URLs, you can set a daily timed access quota by category, category group, or classification. Quotas allow access for a specified length of time or a specified traffic bandwidth, calculated separately for each user. Quotas are reset every day at midnight.

Users must authenticate with the FortiGate unit. The quota is applied to each user individually so the FortiGate must be able to identify each user. One way to do this is to configure a security policy using the identity based policy feature. Apply the web filter profile in which you have configured FortiGuard Web Filter and FortiGuard Web Filter quotas to such a security policy.

The use of FortiGuard Web Filter quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

When a user first attempts to access a URL, they're prompted to authenticate with the FortiGate unit. When they provide their user name and password, the FortiGate unit recognizes them, determines their quota allowances, and monitors their web use. The category and classification of each page they visit is checked and FortiGate unit adjusts the user's remaining available quota for the category or classification.

Editing the web filter profile resets the quota timers for all users.

Quota hierarchy

You can apply quotas to categories and category groups. Only one quota per user can be active at any one time. The one used depends on how you configure the FortiGuard Web Filter.

When a user visits a URL, the FortiGate unit queries the FortiGuard servers for the category of the URL. From highest to lowest, the relative priority of the quotas are:

1. Category
2. Category group

Overriding FortiGuard website categorization

In most things there is an exception to the rule. When it comes to the rules about who is allowed to go to which websites in spite of the rules or in this case, policies, it seems that there are more exceptions than to most rules. There are numerous valid reasons and scenarios for exceptions so it follows that there needs to be a way to accommodate this exceptions.

The different methods of override

There are actually two different ways to override web filtering behavior based on FortiGuard categorization of a websites. The second method has 2 variations in implementation and each of the three has a different level of granularity.

1. Using Alternate Categories

   Rating Override

This method manually assigns a specific website to a different Fortinet category or a locally created category.

2. Using Alternate Profiles

   Administrative Override or Allow Blocked Override

   In this method all of the traffic going through the FortiGate unit, using identity based policies and a Web Filtering profile has the option where configured users or IP addresses can use an alternative Web Filter profile when attempting to access blocked websites.

Using Alternate Categories

Web Rating Overrides

There are two approached to overriding the FortiGuard Web Filtering. The first is an identity based method that can be configured using a combination of identity based policies and specifically designed webfilter profiles. This has been addressed in the Firewall Handbook.

The second method is the system wide approach that locally (on the FortiGate Firewall) reassigns a URL to a different FortiGuard Category and even subcategory. This is where you can set assign a specific URL to the FortiGuard Category that you want to you can also set the URL to one of the Custom Categories that you have created

The Web Rating Overrides option is available because different people will have different criteria for how they categorize websites. Even is the criteria is the same an organization may have reason to block the bulk of a category but need to be able to access specific URLs that are assigned to that category.

A hypothetical example could be that a website, example.com is categorized as being in the Sub-Category Pornography. The law offices of Barrister, Solicitor and Lawyer do not want their employees looking at pornography at work so they have used the FortiGuard Webfilter to block access to sites that have been assigned to the Category “Pornography”. However, the owners of example.com are clients of the law office and they are aware that example.com is for artists that specialize in nudes and erotic images. In this case to approaches can be taken. The first is that the Rating Override function can be used to assign example.com to Nudity and Risque instead of Pornography for the purposes of matching the criteria that the law office goes by or the site can be assigned to a Custom Category that is not blocked because the site belongs to one of their clients and they always want to be able to access the site.

Another hypothetical example from the other side of the coin. A private school has decided that a company that specializes in the online selling of books that could be considered inappropriate for children because of their violent subject matter, should not be accessible to anyone in the school. The categorization by Fortinet of the site example2.com is General Interest - Business with the subcategory of Shopping and Auction, which is a category that is allowed at the school. In this case they school could reassign the site to the Category Adult Material which is a blocked category.

Local or Custom Categories

User-defined categories can be created to allow users to block groups of URLs on a per-profile basis. The categories defined here appear in the global URL category list when configuring a web filter profile. Users can rate URLs based on the local categories.

Users can create user-defined categories then specify the URLs that belong to the category. This allows users to block groups of web sites on a per profile basis. The ratings are included in the global URL list with associated categories and compared in the same way the URL block list is processed.

The local assignment of a category overrides the FortiGuard server ratings and appear in reports as “Local” Categories or “Custom” Categories depending on the context.

In the CLI, they are referred to as Local categories.

To create a Local Category:

```
config webfilter ftgd-local-cat
   edit local_category_1
      set id 140
   end
```

In the GUI they are referred to as Custom Categories. There is a way to create a new category in the Web Based Manager.

1. Go to **Security Profiles** > **Advanced** > **Web Rating Overrides**.
2. Instead of creating a new override, you can choose the “**Custom Categories**” icon in the top menu bar.
3. From the new window select **Create New**.
4. A new row will appear at the bottom of the list of categories with a field on the left highlighted and the message “**This field is required**”. Enter the name of the custom category in this field.
5. Select **Enter**.

Configuring Rating Overrides

1. Go to **Security Profiles** > **Web Filter** > **Web Rating Overrides.**
2. Select **Create New**
3. Type in the **URL** field the URL of the Website that you wish to recategorize.
4. Select the **Lookup Rating** button to verify the current categorization that is being assigned to the URL.
5. Change the **Category** field to one of the more applicable options from the drop down menu.
6. Change the **Sub-Category** field to a more narrowly defined option within the main category.
7. Select **OK**.

It is usually recommended that you choose a category that you know will be addressed in existing Webfilter profiles so that you will not need to engage in further configuration.

Local Category Scenarios

Scenario 1: The configuration of the domain name overrides the configuration for the subdirectory.

Depending on the URL specified or other aspects of configuration, the configuration of a local or custom category may not take effect. Consider a scenario where you have defined:

- example.com – local rating as “category 1”, action set to Block
- example.com/subdirectory – local rating as “category 2”, action set to Monitor
- example.com/subdirectory/page.html – local rating as “category 3”, action set to Warning

If a user browses to “example.com", access will be blocked. If a user browses to example.com/subdirectory, access will also be blocked,even though that address was configured to be part of category2. The configuration of the domain name overrides the configuration for the subdirectory.

However, if you configure a specific HTML page differently than the domain name, then that

configuration will apply. In this scenario, the user will see a Warning message but will be able to pass through to the page.

Scenario 2: User-defined local ratings and SNI matches

In this scenario, local categories are defined and sites are added to those categories.

- There is no behavioral difference if the hostname is sent from from ClientHello SNI or from HTTP request-url.
- The SNI will be used as hostname for https certificate-inspection or ssl-exempt.
- If a valid SNI exist, then SNI will be used as the domain name for url rating instead of CN in the server certificate.
- For the local rating, "example.com" will match "test.example.com", but will not match "another_example.com".

Using Alternate Profiles

Allow Blocked Overrides or Web Overrides

The Administrative Override feature for Web Filtering was added and is found by going to **Security Profiles > Web Filter** and then enabling Allow Blocke Override. This opening window will display a listing of all of the overrides of this type. The editing window referred to the configuration as an Administrative Override.

The Concept

When a Web filter profile is overridden it does not necessarily remove all control and restrictions that were previously imposed by the Web Filter. The idea is to replace a restrictive filter with a different one. In practice, it makes sense that this will likely be a profile that is less restrictive the the original one but there is nothing that forces this. The degree to which that the alternate profile is less restrictive is open. It can be as much as letting the user access everything on the Internet or as little as allowing only one addition website. The usual practice though is to have as few alternate profiles as are needed to allow approved people to access what they need during periods when an exception to the normal rules is needed but still having enough control that the organizations web usage policies are not compromised.

You are not restricted to having only one alternative profile as an option to the existing profile. The new profile depends on the credentials or IP address making the connection. For example, John connecting through the "Standard" profile could get the "Allow_Streaming_Video" profile while George would get the "Allow_Social_ Networking_Sites" profile.

The other thing to take into account is the time factor on these overrides. They are not indefinite. The longest that an override can be enabled is for 1 year less a minute. Often these overrides are set up for short periods of time for specific reasons such as a project. Having the time limitation means that the System Administrator does not have to remember to go back and turn the feature off after the project is finished.

Identity or Address

In either case what these override features do is, for specified users, user groups or IP addresses, allow sites blocked by Web Filtering profiles to be overridden for a specified length of time. The drawback of this method of override is that it takes more planning and preparation than the rating override method. The advantage is that once this has been set up, this method requires very little in the way of administrative overhead to maintain.

When planning to use the alternative profile approach keep in mind the following: In Boolean terms, one of the following "AND" conditions has to be met before overriding the Web Filter is possible

Based on the IP address:

- The Web Filter profile must be specified as allowing overrides
- AND the user's computer is one of the IP addresses specified
- AND the time is within the expiration time frame.

While the conditions are fewer for this situation there is less control over who has the ability to bypass the filtering configured for the site. All someone has to do is get on a computers that is allowed to override the Web Filter and they have access.

Based on user group:

- The Web Filter profile must be specified as allowing overrides
- AND the policy the traffic is going through must be identity based
- AND the user's credentials matches the identity credentials specified
- AND the time is within the expiration time frame.

This method is the one most likely to be used as it gives more control in that the user has to have the correct credential and more versatile because the user can use the feature from any computer that uses the correct policy to get out on the Internet.

Settings

When using an alternate profile approach to Web Filter overrides the following settings are used to determine authentication and outcome. Not every setting is used in both methods but enough of them are common to describe them collectively.

Apply to Group(s)

This is found in the Allow Blocked Overrides configuration. Individual users can not be selected. You can select one or more of the User Groups that are recognized my the FortiGate unit, whether they are local to the system or from a third part authentication device such as a AD server through FSSO.

Original Profile

This is found in the Administrative Override configuration. In the Allow Blocked Overrides setting the configuration is right inside the profile so there was no need to specify which profile was the original one, but the Administrative Override setup is done separately from the profiles themselves.

Assign to Profile or New Profile

Despite the difference in the name of the field, this is the same thing in both variations of the feature. You select from the drop down menu the alternate Web Filter Profile that you wish to set up for this override.

Scope or Scope Range

When setting up the override in the "Allow Blocked Overrides" variation you are given a drop down menu next to the field name Scope while in the Administrative Override configuration you are asked to select a radio button next to the same options. In both cases this is just a way of selecting which form of credentials will be required to approve the overriding of the existing Web Filter profile.

When the Web Filter Block Override message page appears it will display a field named "Scope:" and depending on the selection, it will show the type of credentials used to determine whether or not the override is allowed. The available options are:

- **User**
  This means that the authentication for permission to override will be based on whether or not the user is using a specific user account.

- **User Group**
  This means that the authentication for permission to override will be based on whether on not the user account supplied as a credential is a member of the specified User Group.

- **IP**
  This means that the authentication for permission to override will be based on the IP address of the computer that was used to authenticate. This would be used with computers that have multiple users. Example: If Paul logs on to the computer, engages the override using his credentials and then logs off, if the scope was based on the IP address of the computer, anybody logging in with any account on that computer would now be using the alternate override Web Filter profile.

  When entering an IP address in the Administrative Override version, only individual IP addresses are allowed.

  Differences between IP and Identity based scope

  - Using the IP scope does not require the use of an Identity based policy.
  - When using the Administrative Override variation and IP scope, you may not see a warning message when you change from using the original Web Filter profile to using the alternate profile. There is no requirement for credentials from the user so, if allowed, the page will just come up in the browser.
- **Ask**
  This option is available only in the "Allowed Blocked Overrides" variation and when used configures the message page to ask which scope the user wished to use. Normally, when the page appears the scope options are greyed out an not editable, but by using the ask option the option is dark and the user can choose from the choice of:
  - User
  - User Group
  - IP Address

- **Duration Mode**
  This option is available only in the "Allowed Blocked Overrides" variation. The Administrative Override sets a specified time frame that is always used for that override. The available options from the drop down menu are:
  - **Constant**
    Using this setting will mean that what ever is set as the duration will be the length of time that the override will be in effect. If the Duration variable is set to 15 minutes the length of the override will always be 15 minutes. The option will be visible in the Override message page but the setting will be greyed out.
  - **Ask**

    Using this setting will give the person the option of setting the duration to the override when it is engaged. The duration time which is greyed out if the Constant setting is used will be dark and editable. The user can set the duration in terms of Day, Hours and or Minutes.

- **Duration**
  Duration is on of the areas where the two variations takes a different approach, on two aspects of the setting. As already indicated the "Administrative Override" only uses a static time frame there is no option for the user to select on the fly how long it will last. The other way in which the two variation differ is that the "Allow Blocked Overrides" starts the clock when the user logs in with his credentials. For example, if the duration is 1 hour and John initiates an override at 2:00 p.m. on January 1, at the end of that hour he will revert back to using the original profile but he can go back and re-authenticate and and start the process over again. The Administrative override variation starts the clock from when the override was configured, which is why is shows an expiration date and time when your are configuring it.

  This option, which is available when the Duration Mode is set to Constant is the time in minutes that the override will last when engaged by the user.

  When setting up a constant duration in the Web Based Interface, minutes is the only option for units of time. To set a longer time frame or to use the units of hours or days you can use the CLI.

```
config webfilter profile
   edit <name of webfilter profile>
      config override
         set ovrd-dur <###d##h##m>
      end
```

When configuring the duration you don't have to set a value for a unit you are not using. If you are not using days or hours you can use:

```
set ovrd-dur 30m
```

instead of:

```
set ovrd-dur 0d0h30m
```

However, each of the units of time variable has their own maximum level:

```
###d cannot be more than 364
##h cannot be more than 23
##m cannot be more than 59
```

So the maximum length that the override duration can be set to is 364 days, 23 hours, and 59 minutes(a minute shy of 1 year) .

SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch for the supported search sites enforces its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature. For example, on a Google search it would mean adding the string “&safe=active” to the URL in the search.

The search sites supported are:

- Google
- Yahoo
- Bing
- Yandex

Enabling SafeSearch — CLI

```
config webfilter profile
   edit default
      config web
         set safe-search url
      end
   end
```

This enforces the use of SafeSearch in traffic controlled by the firewall policies using the web filter you configure.

Search Keywords

There is also the capability to log the search keywords used in the search engines.

YouTube Education Filter

YouTube for Schools is a way to access educational videos from inside a school network. This YouTube feature gives schools the ability to access a broad set of educational videos on YouTube EDU and to select the specific videos that are accessible from within the school network.

Before this feature can be used an account has to be set up for the school with YouTube. Once the account is set up a unique ID will be provided. This ID becomes part of the filter that is used to all access to the educational content of YouTube for use in schools even if YouTube is blocked by the policy.

More details can be found by going to http://www.youtube.com/schools.

Enabling YouTube Education Filter in CLI

```
config webfilter profile
   edit default
      config web
         set safe-search url header
         set youtube-edu-filter-id ABCD1234567890abcdef
      end
   end
```

Static URL Filter

You can allow or block access to specific URLs by adding them to the Web Site Filter list. You add the URLs by using patterns containing text and regular expressions. The FortiGate unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message instead.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to ftp:// ftp.example.com. Instead, use firewall policies to deny ftp connections.

When adding a URL to the URL filter list, follow these rules:

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and file name to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls access to the news page on this web site.

- To control access to all pages with a URL that ends with example.com, add `example.com` to the filter list. For example, adding example.com controls access to www.example.com, mail.example.com, www.finance.example.com, and so on.
- Control access to all URLs that match patterns using text and regular expressions (or wildcard characters). For example, `example.*` matches example.com, example.org, example.net and so on.

URLs with an action set to exempt or monitor are not scanned for viruses. If users on the network download files through the FortiGate unit from a trusted web site, add the URL of this web site to the URL filter list with an action to pass it so the FortiGate unit does not virus scan files downloaded from this URL.

URL formats

When adding a URL to the URL filter list, follow these rules:

How URL formats are detected when using HTTPS

If your unit does not support SSL content scanning and inspection or if you have selected the **URL filtering** option in web content profile for **HTTPS content filtering mode** under **Protocol Recognition**, filter HTTPS traffic by entering a top level domain name, for example, `www.example.com`. HTTPS URL filtering of encrypted sessions works by extracting the CN from the server certificate during the SSL negotiation. Since the CN only contains the domain name of the site being accessed, web filtering of encrypted HTTPS sessions can only filter by domain names.

If your unit supports SSL content scanning and inspection and if you have selected Deep Scan, you can filter HTTPS traffic in the same way as HTTP traffic.

How URL formats are detected when using HTTP

URLs with an action set to exempt are not scanned for viruses. If users on the network download files through the unit from trusted web site, add the URL of this web site to the URL filter list with an action set to exempt so the unit does not virus scan files downloaded from this URL.

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and filename to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns created using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.
- Fortinet URL filtering supports standard regular expressions.

If virtual domains are enabled on the unit, web filtering features are configured globally. To access these features, select **Global Configuration** on the main menu.

URL Filter actions

You can select one of four actions for how traffic will be treated as it attempts to reach a site in the list.

Block

Attempts to access any URLs matching the URL pattern are denied. The user will be presented with a replacement message.

Allow

Any attempt to access a URL that matches a URL pattern with an allow action is permitted. The traffic is passed to the remaining antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters, and antivirus scanning.

Allow is the default action. If a URL does not appear in the URL list, it is permitted.

Monitor

Traffic to, and reply traffic from, sites matching a URL pattern with a monitor be allowed through in the same way as the “Allow” action. The difference with the Monitor action being that a log message will be generated each time a matching traffic session is established. The requests will also be subject to all other Security Profiles inspections that would normally be applied to the traffic.

Exempt

Exempt allows trusted traffic to bypass the antivirus proxy operations, but it functions slightly differently. In general, if you’re not certain that you need to use the **Exempt** action, use **Monitor**.

HTTP 1.1 connections are persistent unless declared otherwise. This means the connections will remain in place until closed or the connection times out. When a client loads a web page, the client opens a connection to the web server. If the client follows a link to another page on the same site before the connection times out, the same connection is used to request and receive the page data.

When you add a URL pattern to a URL filter list and apply the **Exempt** action, traffic sent to and replies traffic from sites matching the URL pattern will bypass all antivirus proxy operations. The connection itself inherits the exemption. This means that all subsequent reuse of the existing connection will also bypass all antivirus proxy operations. When the connection times out, the exemption is cancelled.

For example, consider a URL filter list that includes `example.com/files` configured with the Exempt action. A user opens a web browser and downloads a file from the URL `example.com/sample.zip`. This URL does not match the URL pattern so it is scanned for viruses. The user then downloads `example.com/files/beautiful.exe` and since this URL does match the pattern, the connection itself inherits the exempt action. The user then downloads `example.com/virus.zip`. Although this URL does not match the exempt URL pattern, a previously visited URL did, and since the connection inherited the exempt action and was re-used to download a file, the file is not scanned.

If the user next goes to an entirely different server, like `example.org/photos`, the connection to the current server cannot be reused. A new connection to example.org is established. This connection is not exempt. Unless the user goes back to example.com before the connection to that server times out, the server will close the connection. If the user returns after the connection is closed, a new connection to example.com is created and it is not exempt until the user visits a URL that matches the URL pattern.

Web servers typically have short time-out periods. A browser will download multiple components of a web page as quickly as possible by opening multiple connections. A web page that includes three photos will load more quickly if the browser opens four connections to the server and downloads the page and the three photos at the same time. A short time-out period on the connections will close the connections faster, allowing the server to avoid unnecessarily allocating resources for a long period. The HTTP session time-out is set by the server and will vary with the server software, version, and configuration.

Using the **Exempt** action can have unintended consequences in certain circumstances. You have a web site at example.com and since you control the site, you trust the contents and configure `example.com` as exempt. But example.com is hosted on a shared server with a dozen other different sites, each with a unique domain name. Because of the shared hosting, they also share the same IP address. If you visit example.com, your connection your site becomes exempt from any antivirus proxy operations. Visits to any of the 12 other sites on the same server will reuse the same connection and the data you receive is exempt from scanned.

Use of the **Exempt** action is not suitable for configuration in which connections through the FortiGate unit use an external proxy. For example, you use proxy.example.net for all outgoing web access. Also, as in the first example, URL filter list that includes a URL pattern of `example.com/files` configured with the **Exempt** action. Users are protected by the antivirus protection of the FortiGate unit until a user visits a URL that matches the of `example.com/files` URL pattern. The pattern is configured with the **Exempt** action so the connection to the server inherits the exemption. With a proxy however, the connection is from the user to the proxy. Therefore, the user is entirely unprotected until the connection times out, no matter what site he visits.

Ensure you are aware of the network topology involving any URLs to which you apply the Exempt action.

Status

The Web Site Filter has the option to either enable or disable individual web sites in the list. This allows for the temporary removal of the actions against a site so that it can be later reengaged without having to rewrite the configuration.

Configuring a URL filter

Each URL filter list can have up to 5000 entries. For this example, the URL www.example*.com will be used. You configure the list by adding one or more URLs to it.

To add a URL to a URL filter

1. Go to **Security Profiles > Web Filter**
2. Select a web filter to edit.
3. In the URL filter, select **Create New**.
4. Enter the URL, without the “http”, for example: `www.example*.com`.
5. Select a **Type**: **Simple** (see below), **Wildcard**, or **Regular Expression**.
6. In this example, select **Wildcard**.
7. Select the **Action** to take against matching URLs: Exempt, Block, Allow, or Monitor.
8. Select **Enable**.
9. Select **OK.**

'Simple' filter type

If you select the **Simple** filter type for a URL filter, the syntax is performing an exact match. Note, however, that the domain and path are separate entities in HTTP despite the fact that a user types them as a single entity and, in the case of 'simple', the rules for each part (domain and path) are different.

The 'domain' part

For the domain part, the goal of the 'simple' format is to make it easy to block a domain and all its subdomains, such that the admin only has to type “address.xy" to block "address.xy", "www.address.xy", "talk.address.xy", etc. but *not* block “youraddress.xy" or "www.youraddress.xy" which are different domains from "address.xy”.

Also, the actual domain does not include http:// or https:// so this should *not* be entered or the URL filter will try to match a domain starting with http. For this reason, when you enter http:// in the URL filter via the GUI, it is automatically removed.

A trailing ‘/‘ with the domain is not needed. The GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

The 'path' part

For the path part, an exact match takes place. For example:

www.address.xy/news

blocks anything that starts with that exact path. So this matches:

www.address.xy/newsies
www.address.xy/newsforyou
www.address.xy/news/co
etc.

Also:

www.address.xy/new

likewise blocks the same as above but includes:

/newt
/newp
etc.

which is a much broader filter, matching:

www.address.xy/newstand/co
www.address.xy/news/co
etc.

In other words, the more you specify of the path, the more strictly it will match.

Here as well a trailing ‘/‘ with the URL path is not needed, the GUI URL filter will automatically trim this, but when using the API to provide the per-user BWL it will not!

Please take this into account. Better not to use it as it might give unexpected results.

Referer URL

A new variable has been added to the Static URL Filter, `referrer-host`. If a referer is specified, the hostname in the referer field of the HTTP require will be compared for any entry that contains the matching URL. If the referer matches, then the specified action will be performed by proxy.

Configuring in the GUI

The configuration can be done in the GUI but only if advance webfiltering features have been enabled by entering the following commands in the CLI:

```
config system global
   set gui-webfilter-advanced enable
end
```

After this command is used, a new column will be created in **Security Profiles > Web Filter > Static URL Filter** to set the referer.

Configuring in the CLI

When specifying the URL filter, it needs to be identified by its ID. The URLs are listed under each entry.

To find the ID number:

```
config webfilter urlfilter
   edit ?
```

A list of the current URL filters will be listed with their ID numbers in the left column.

The syntax in the CLI for configuring an entry is:

```
config webfilter urlfilter
   edit <ID>
      config entries
         edit 1
            set url <url>
            set referrer-host <url>
            set type {simple | regex | wildcard}
            set action {block | allow | monitor | exempt}
            set status {enable | disable}
         end
      end
   end
```

Web content filter

You can control web content by blocking access to web pages containing specific words or patterns. This helps to prevent access to pages with questionable material. You can also add words, phrases, patterns, wild cards and Perl regular expressions to match content on web pages. You can add multiple web content filter lists and then select the best web content filter list for each web filter profile.

Enabling web content filtering involves three separate parts of the FortiGate configuration.

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day.

- The web filter profile specifies what sort of web filtering is applied.
- The web content filter list contains blocked and exempt patterns.

The web content filter feature scans the content of every web page that is accepted by a security policy. The system administrator can specify banned words and phrases and attach a numerical value, or score, to the importance of those words and phrases. When the web content filter scan detects banned content, it adds the scores of banned words and phrases in the page. If the sum is higher than a threshold set in the web filter profile, the FortiGate unit blocks the page.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a web content filter list.
2. Add patterns of words, phrases, wildcards, and regular expressions that match the content to be blocked or exempted.
3. You can add the patterns in any order to the list. You need to add at least one pattern that blocks content.
4. In a web filter profile, enable the web content filter and select a web content filter list from the options list.

To complete the configuration, you need to select a security policy or create a new one. Then, in the security policy, enable **Webfilter** and select the appropriate web filter profile from the list.

Creating a web filter content list

You can create multiple content lists and then select the best one for each web filter profile. Creating your own web content lists can be accomplished only using the CLI.

This example shows how to create a web content list called inappropriate language, with two entries, offensive and rude.

To create a web filter content list

```
config webfilter content
   edit 3
      set name "inappropriate language"
      config entries
         edit offensive
            set action block
            set lang western
            set pattern-type wildcard
            set score 15
            set status enable
         next
         edit rude
            set action block
            set lang western
            set pattern-type wildcard
            set score 5
            set status enable
         end
      end
   end
```

Configuring a web content filter list

Once you have created the web filter content list, you need to add web content patterns to it. There are two types of patterns: **Wildcard** and **Regular Expression**.

You use the **Wildcard** setting to block or exempt one word or text strings of up to 80 characters. You can also use the wildcard symbols, such as “*” or “?”, to represent one or more characters. For example, as a wildcard expression, forti*.com will match fortinet.com and forticare.com. The “*” represents any kind of character appearing any number of times.

You use the **Regular Expression** setting to block or exempt patterns of Perl expressions, which use some of the same symbols as wildcard expressions, but for different purposes. The “*” represents the character before the symbol. For example, forti*.com will match fortiii.com but not fortinet.com or fortiice.com. The symbol “*” represents “i” in this case, appearing any number of times. RP: Add a regex example.

The maximum number of web content patterns in a list is 5000.

How content is evaluated

Every time the web content filter detects banned content on a web page, it adds the score for that content to the sum of scores for that web page. You set this score when you create a new pattern to block the content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the sum of scores equals or exceeds the threshold score, the web page is blocked. The default score for web content filter is 10 and the default threshold is 10. This means that by default a web page is blocked by a single match. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

Banned words or phrases are evaluated according to the following rules:

- The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.
- The score for any word in a phrase without quotation marks is counted.
- The score for a phrase in quotation marks is counted only if it appears exactly as written.

The following table describes how these rules are applied to the contents of a web page. Consider the following, a web page that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.”

Banned Pattern Rules

Banned pattern	Assigned score	Score added to the sum for the entire page	Threshold score	Comment
word	20	20	20	Appears twice but only counted once. Web page is blocked.
word phrase	20	40	20	Each word appears twice but only counted once giving a total score of 40. Web page is blocked
word sentence	20	20	20	“word” appears twice, “sentence” does not appear, but since any word in a phrase without quotation marks is counted, the score for this pattern is 20. Web page is blocked.
“word sentence”	20	0	20	“This phrase does not appear exactly as written. Web page is allowed.
“word or phrase”	20	20	20	This phrase appears twice but is counted only once. Web page is blocked.

Enabling the web content filter and setting the content threshold

When you enable the web content filter, the web filter will block any web pages when the sum of scores for banned content on that page exceeds the content block threshold. The threshold will be disregarded for any exemptions within the web filter list.

Advanced web filter configurations

Allow websites when a rating error occurs

Enable to allow access to web pages that return a rating error from the FortiGuard Web Filter service.

If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines what access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.

ActiveX filter

Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

Block HTTP redirects by rating

Enable to block HTTP redirects.

Many web sites use HTTP redirects legitimately but in some cases, redirects may be designed specifically to circumvent web filtering, as the initial web page could have a different rating than the destination web page of the redirect.

This option is not supported for HTTPS.

Block Invalid URLs

Select to block web sites when their SSL certificate CN field does not contain a valid domain name.

FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs:

- If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name.
- If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.

Enabling the Web Filter profile to block a particular category and enabling the Application Control profile will not result in blocking the URL. This occurs because Proxy and Flow based profiles cannot operate together.

To ensure replacement messages show up for blocked URLs, switch the Web Filter to Flow based inspection.

Cookie filter

Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.

Provide Details for Blocked HTTP 4xx and 5xx Errors

Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to circumvent web filtering.

HTTP POST action

Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server.

The available actions include:

Comfort

Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic.

The client comforting settings used are those defined in the Proxy Options profile selected in the security policy.

Block

Block the HTTP POST command. This will limit users from sending information and files to web sites.

When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.

Java applet filter

Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.

Rate Images by URL

Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category.

Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.

Rate URLs by Domain and IP Address

Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter.

If the rating determined by the domain name and the rating determined by the IP address defer the Action that is enforce will be determined by a weighting assigned to the different categories. The higher weighted category will take precedence in determining the action. This will have the side effect that sometimes the Action will be determined by the classification based on the domain name and other times it will be determined by the classification that is based on the IP address.

FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.

An example of how this would work would be if a URL's rating based on the domain name indicated that it belonged in the category Lingerie and Swimsuit, which is allowed but the category assigned to the IP address was Pornography which has an action of Block, because the Pornography category has a higher weight the effective action is Block.

Web resume download block

Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off.

This prevents the unintentional download of viruses hidden in fragmented files.

Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.

Restrict Google account usage to specific domains

This feature allows the blocking of access to some Google accounts and services while allowing access to accounts that are included in the domains specified in the exception list.

Block non-English character URLs

The FortiGate will not successfully block non-English character URLs if they are added to the URL filter. In order to block access to URLs with non-English characters, the characters must be translated into their international characters.

Browse to the non-English character URL (for example, http://www.fortinet.com/pages/ที่ นี่ -ไม่ มี เศษรั ฐประหารให้ ใครแดก/338419686287505?ref=stream).

On the FortiGate, use the URL shown in the FortiGate GUI and add it the list of blocked URLs in your URL filter (for example, http://www.fortinet.com/pages/%E0%B8%97%E0%B8%B5%E0%B9%88%E0%B8%99%E0%B8%B5%E0%B9%88-%E0%B9%84%E0%B8%A1%E0%B9%88%E0%B8%A1%E0%B8%B5%E0%B9%80%E0%B8%A8%E0%B8%A9%E0%B8%A3%E0%B8%B1%E0%B8%90%E0%B8%9B%E0%B8%A3%E0%B8%B0%E0%B8%AB%E0%B8%B2%E0%B8%A3%E0%B9%83%E0%B8%AB%E0%B9%89%E0%B9%83%E0%B8%84%E0%B8%A3%E0%B9%81%E0%B8%94%E0%B8%81/338419686287505?ref=stream).

Once added, further browsing to the URL will result in a blocked page.

CLI Syntax

```
config webfilter urlfilter
   edit 1
      set name "block_international_character_urls"
         config entries
            edit 1
               set url "www.fortinet.com/pages/2.710850E-3120%B8%E0%B8%B53.231533E-
                   3170%B9%E0%B8%E0%B8%B53.231533E-3170%B9%88-3.230415E-
                   3170%B9%E0%B80X0.000000063CD94P-102211.482197E-
                   3230%B9%E0%B80X0.0007FBFFFFCFP-102210.000000E+000%B8%B51.828043E-

                   3200%B9%E0%B8%E0%B8%81/338419686287505?ref=stream"
               set action block
            next
         end
   next
end

config webfilter urlfilter
   edit 2
      set name "block_international_character_urls"
   next
end

config webfilter profile
   edit "block_international_character_urls"
   next
end

config firewall policy
   edit 3
      set uuid cf80d386-7bcf-51e5-6e87-db207e3f0fa8
```

```
        set srcintf "port1"
        set dstintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set logtraffic all
        set webfilter-profile "block_international_character_urls"
        set profile-protocol-options "default"
        set ssl-ssh-profile "certificate-inspection"
        set nat enable
    next
end
```

Configuring Web Filter Profiles

Enabling FortiGuard Web Filter

FortiGuard Web Filter is enabled and configured within web filter profiles by enabling FortiGuard Categories. The service is engaged by turning on the Web Filter profile and selecting a profile that has FortiGuard Categories enabled on one or more active policies being run by the firewall.

There is also a system wide setting for the enabling or disabling of FortiGuard Web Filter that is only in the CLI.

```
config system fortiguard
   set webfilter-force-off
```

The two options on this setting are enable or disable. The syntax of the settings name is “force-off” so in order to enable FortiGuard Webfilter you have to choose disable for the setting and enable if you want to turn it off.

General configuration steps

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile or edit an existing one.
3. Select an **Inspection Mode**.
4. If you are using FortiGuard Categories, enable the FortiGuard Categories, select the categories and select the action to be performed.
5. Configure any **Quotas** needed. (Proxy Mode)
6. Allow blocked override if required.(Proxy Mode)
7. Set up **Safe Search** settings and/or YouTube Education settings. (Proxy & Flow-based)
8. Configure **Static URL Settings**. (All Modes)
9. Configure **Rating Options**. (All Modes)
10. Configure **Proxy Options**.
11. Save the filter and web filter profile.
12. To complete the configuration, you need to select the security policy controlling the network traffic you want to restrict. Then, in the security policy, enable Web Filter and select the appropriate web filter profile from the list.

Configuring FortiGuard Web Filter settings

FortiGuard Web Filter includes a number of settings that allow you to determine various aspects of the filtering behavior.

Getting to the Edit Web Filter Profile configuration window

Once you have gotten to the profile configuration window there are a number of settings that can be used, most of which are optional. We will treat each of these options separately, but present the common instructions of how to get to the profile editing page here.

1. Go to **Security Profiles > Web Filter**.
2. Determine if you wish to create a new profile, edit an existing one, or clone and then edit an existing one.
   a. New profile:
      i. Select the **Create New** icon, in the upper right of the window (looks like a plus sign in a circle) **OR**
      ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text). Select the **Create New** icon in the upper left.
   b. Edit existing profile:
      i. Select the name of the profile that you wish to edit from the drop-down menu **OR**
      ii. Select the **List** icon, in the upper right (looks like a white rectangle with lines like text. Highlight the name of the profile from the list and select **Edit** from the options above the list.
   c. Clone a profile:
      i. Select **Clone** icon in the upper right corner of the window (looks like one sheet of lined paper overlapping another) **OR**
      ii. Select the **List**icon, in the upper right (looks like a white rectangle with lines like text. Highlight the name of the profile from the list and select **Clone** from the options above the list.
3. Make sure there is a valid name, and comment if you want.
4. Configure the settings to best achieve your specific requirements
5. Select **Apply** or **OK, depending on whether you are editing or creating a new profile.**.

In older versions of FortiOS there was a character limitation for the URL of 2048 bytes or approximately 321 characters. If the URL you were trying to reach was longer the URL sent to FortiGuard would be truncated and the service would be unable to categorize the site. Starting in version 5 of the firmware the parsed URL has been increase to 4 Kilobytes, effectively doubling the length of a URL capable of being categorized.

To configure the FortiGuard Web Filter categories

1. Go to the **Edit Web Filter Profile** window.
2. The category groups are listed in a widget. You can expand each category group to view and configure every sub-category individually within the groups. If you change the setting of a category group, all categories within the group inherit the change.
3. Select the category groups and categories to which you want to apply an action.
   To assign an action to a category left click on the category and select from the pop up menu.
4. Enable **Enforce Quota** to activate the quota for the selected categories and category groups.

5. Select **Hours**, **Minutes**, or **Seconds** and enter the number of hours, minutes, or seconds. This is the daily quota allowance for each user.
6. Select **Apply** or **OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

If you look at your logs carefully, you may notice that not every URL connection in the log shows a category. They are left blank. If you take one of those URL and enter it in the FortiGuard website designed to show the category for a URL it will successfully categorize it.

The reason for this is that to optimize speed throughput and reduce the load on the FortiGuard servers the FortiGate does not determine a category rating on scripts and css files.

Configuring FortiGuard Category Quotas

1. Go to the Edit Web Filter Profile window
2. Verify that the categories that need to have quotas on them are set to one of the actions:
   - Monitor
   - Warning
   - Authenticate
3. Select the blue triange expand symbol to show the widget for Quotas
4. Select **Create New** or **Edit**.
5. In the **New/Edit Quota** window that pops up enable or disable the specific categories that the quota will apply to.
6. At the bottom of the widget, select **Hours**, **Minutes**, or **Seconds** and enter the number of hours, minutes, or seconds. This is the daily quota allowance for each user.
7. Select **Apply or OK**.
8. Continue with any other configuration in the profile
9. Select **Apply or OK**.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

Timed access quota can be configured through the GUI. You can also use CLI commands to configure a bandwidth quota. The following commands show how to add a quota of 10MB of bandwidth. Refer to the FortiOS 5.2 CLI Reference Guide for more information.

```
config webfilter profile
   edit default
      config ftgd-wf
         config quota
            edit <id>
               set category <id>
               set type traffic
               set unit MB
               set value 10
            end
         end
      end
```

Configure Allowed Blocked Overrides

1. Go to the **Edit Web Filter Profile window.**
2. Enable **Allow Blocked Override**
3. In the Apply to Group(s) field select the desired **User Group**
4. In the Assign to Profile field, select the desired profile

Configure Search Engine Section

There are 2 primary configuration settings in this section.

Enable Safe Search

To enable the Safe Search settings

1. Go to the **Edit Web Filter Profile window.**
2. Enable **Safe Search**
3. Enable Search Engine Safe Search
4. Enable YouTube Filter
   a. Enter the YouTube User ID in the Text field

Log All Search Keywords

In the GUI, the configuration setting is limited to a checkbox.

Configure Static URL Filter

Web Content Filter

To enable the web content filter and set the content block threshold

1. Go to the **Edit Web Filter Profile window**.
2. In the **Static URL Filter section** enable **Web Content Filter**.
3. Select **Create New**.
4. Select the **Pattern Type**.
5. Enter the content **Pattern**.
6. Enter the **Language** from the dropdown menu.
7. Select **Block** or **Exempt**, as required, from the **Action** list.
8. Select **Enable**.
9. Select **OK.**

Configure Rating Options

Allow Websites When a Rating error Occurs

In the GUI, the configuration setting is limited to a checkbox.

Rate URLs by Domain and IP Address

In the GUI, the configuration setting is limited to a checkbox.

Block HTTP Redirects by Rating

In the GUI, the configuration setting is limited to a checkbox.

Rate Images by URL (Blocked images will be replaced with blanks)

In the GUI, the configuration setting is limited to a checkbox.

Configure Proxy Options

Restrict Google Account Usage to Specific Domains

Configuring the feature in the GIU

Go to **Security Profiles > Web Filter**.

In the **Proxy Options** section, check the box next to **Restrict to Corporate Google Accounts Only**.

Use the **Create New** link within the widget to add the appropriate Google domains that will be allowed.

Configuring the feature in the CLI

To configure this option in the CLI, the URL filter must refer to a web-proxy profile that is using the Modifying HTTP Request Headers feature. The command is only visible when the action for the entry in the URL filter is set to either allow or monitor.

1. Configure the proxy options:

```
config web-proxy profile
   edit "googleproxy"
      config headers
         edit 1
            set name "X-GoogApps-Allowed-Domains"
            set content "fortinet.com, Ladan.ca"
            end
         end
      end
   end
```

2. Set a web filter profile to use the proxy options

```
config webfilter urlfilter
   edit 1
      config entries
         edit "*.google.com"
            set type wildcard
            set action {allow | monitor}
            set web-proxy-profile <profile>
            end
         end
      end
   end
```

In the CLI, you can also add, modify, and remove header fields in HTTP request when scanning web traffic in proxy-mode. If a header field exists when your FortiGate receives the request, its content will be modified based on the configurations in the URL filter.

Web Resume Download block

In the GUI, the configuration setting is limited to a checkbox.

Provide Details for Blocked HTTP 4xx and 5xx Errors

In the GUI, the configuration setting is limited to a checkbox.

HTTP POST Action

Remove Java Applet Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove ActiveX Filter

In the GUI, the configuration setting is limited to a checkbox.

Remove Cookie Filter

In the GUI, the configuration setting is limited to a checkbox.

Web filtering example

Web filtering is particularly important for protecting school-aged children. There are legal issues associated with improper web filtering as well as a moral responsibility not to allow children to view inappropriate material. The key is to design a web filtering system in such a way that students and staff do not fall under the same web filter profile in the FortiGate configuration. This is important because the staff may need to access websites that are off-limits to the students.

School district

The background for this scenario is a school district with more than 2300 students and 500 faculty and staff in a preschool, three elementary schools, a middle school, a high school, and a continuing education center. Each elementary school has a computer lab and the high school has three computer labs with connections to the Internet. Such easy access to the Internet ensures that every student touches a computer every day.

With such a diverse group of Internet users, it was not possible for the school district to set different Internet access levels. This meant that faculty and staff were unable to view websites that the school district had blocked. Another issue was the students' use of proxy sites to circumvent the previous web filtering system. A proxy server acts as a go-between for users seeking to view web pages from another server. If the proxy server has not been blocked by the school district, the students can access the blocked website.

When determining what websites are appropriate for each school, the district examined a number of factors, such as community standards and different needs of each school based on the age of the students.

The district decided to configure the FortiGate web filtering options to block content of an inappropriate nature and to allow each individual school to modify the options to suit the age of the students. This way, each individual

school was able to add or remove blocked sites almost immediately and have greater control over their students' Internet usage.

In this simplified example of the scenario, the district wants to block any websites with the word **example** on them, as well as the website www.example.com. The first task is to create web content filter lists for the students and the teachers.

Create a Webfilter for the students

1. Go to **Security Profiles** > **Web Filter.**
2. Select the Create New icon.
3. Enter the name "Students" in the name field.
4. For the Inspection mode, select Proxy.
5. Enable FortiGuard Categories.
   a. Set to block the following categories:
   - Potentially Liable
   - Adult/Mature Content
   - Security Risk

URL Content

6. Check Enable Safe Search
   a. Check **Search Engine Safe Search - Google, Yahoo!, Bing, Yandex**
   b. Check **YouTube Education Filter** and enter the YouTube User ID
7. In the Static URL Filter section, check Enable URL Filter.
   a. In the URL Filter widget, Select **Create New**.
      i. In the **URL** field, enter *example*.*
      ii. For the **Type** field, select Wildcard
      iii. For the **Action** field, select Block
      iv. For the **Status** field, check enable
      v. Select **OK**

Web Content Filter

8. In the Static URL Filter section, check Enable Web Content Filter.
   a. In the Web Content Filter widget, select **Create New**.
   b. Enter the name "Teachers" in the name field.
      i. For the **Pattern Type** field, select
      ii. In the **Pattern** field, enter "example"
      iii. For the **Language** field, choose Western
      iv. For the **Action** field, select "Block"
      v. For the **Status** field, check Enable.
      vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check Block HTTP Redirects by Rating

11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **OK**

Create a Webfilter for the Teachers

It might be more efficient if the Teacher Web Content List included the same blocked content as the student list. From time to time a teacher might have to view a blocked page. It would then be a matter of changing the **Action** from **Block** to **Allow** as the situation required. The following filter is how it could be set up for the teachers to allow them to see the “example” content if needed while keeping the blocking inappropriate material condition.

1. Go to **Security Profiles** > **Web Filter.**
2. Select the Create New icon.
3. Enter the name “Teachers” in the name field.
4. For the Inspection mode, select Proxy.
5. Enable FortiGuard Categories.
   a. Set to block the following categories:
   - Potentially Liable
   - Adult/Mature Content
   - Security Risk

URL Content

6. Check Enable Safe Search
   a. Check **Search Engine Safe Search - Google, Yahoo!, Bing, Yandex**
   b. Check **YouTube Education Filter** and enter the YouTube User ID
7. In the Static URL Filter section, check Enable URL Filter.
   a. In the URL Filter widget, Select **Create New**.
      i. In the **URL** field, enter *example*.*
      ii. For the **Type** field, select Wildcard
      iii. For the **Action** field, select Block
      iv. For the **Status** field, check enable
      v. Select **OK**

Web Content Filter

8. In the Static URL Filter section, check Enable Web Content Filter.
   a. In the Web Content Filter widget, select **Create New**.
   b. Enter the name “Teachers” in the name field.
      i. For the **Pattern Type** field, select
      ii. In the **Pattern** field, enter “example”
      iii. For the **Language** field, choose Western
      iv. For the **Action** field, select “Exempt”
      v. For the **Status** field, check Enable.
      vi. Select **OK**
9. Check **Rate URLs by Domain and IP Address**
10. Check Block HTTP Redirects by Rating

11. Check **Rate Images by URL (Blocked images will be replaced with blanks)**
12. Select **OK**

To create a security policy for the students

1. Go to **Policy > Policy > IPv4.**
2. Select the policy being used to manage student traffic.
3. Enable **Web Filter**.
4. Select **Students** from the web filter drop-down list.
5. Select **OK**.

To create a security policy for Teachers

1. Go to **Policy > Policy > IPv4.**
2. Select the policy being used to manage teacher traffic.
3. Enable **Web Filter**.
4. Select **Teachers** from the web filter drop-down list.
5. Select **OK**.
6. Make sure that the student policy is in the sequence before the teachers' policy.

Application control

Using the application control Security Profile feature, your FortiGate unit can detect and take action against network traffic depending on the application generating the traffic. Based on FortiGate Intrusion Protection protocol decoders, application control is a user-friendly and powerful way to use Intrusion Protection features to log and manage the behavior of application traffic passing through the FortiGate unit. Application control uses IPS protocol decoders that can analyze network traffic to detect application traffic even if the traffic uses non-standard ports or protocols.

The FortiGate unit can recognize the network traffic generated by a large number of applications. You can create application control sensors that specify the action to take with the traffic of the applications you need to manage and the network on which they are active, and then add application control sensors to the firewall policies that control the network traffic you need to monitor.

Fortinet is constantly increasing the list of applications that application control can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database and both of these databases have the same version number.

You can find the version of the application control database that is installed on your unit, by going to the **License Information** dashboard widget and find IPS Definitions version.

You can go to the FortiGuard Application Control List to see the complete list of applications supported by FortiGuard. This web page lists all of the supported applications. You can select any application name to see details about the application.

If you enable virtual domains (VDOMs) on the Fortinet unit, you need to configure application control separately for each virtual domain.

The following topics are included in this section:

- Application control concepts
- Application considerations
- Application traffic shaping
- Application control monitor
- Enable application control
- Application control examples

To view the version of the application control database installed on your FortiGate unit, go to the **License Information** dashboard widget and find the **IPS Definitions** version.

To see the complete list of applications supported by FortiGuard Application Control go to the FortiGuard Application Control List. This web page lists all of the supported applications. You can select any application name to see details about the application.

Application control concepts

You can control network traffic generally by the source or destination address, or by the port, the quantity or similar attributes of the traffic itself in the security policy. If you want to control the flow of traffic from a specific application, these methods may not be sufficient to precisely define the traffic. To address this problem, the

application control feature examines the traffic itself for signatures unique to the application generating it. Application control does not require knowledge of any server addresses or ports. The FortiGate unit includes signatures for over 1000 applications, services, and protocols.

Updated and new application signatures are delivered to your FortiGate unit as part of your FortiGuard Application Control Service subscription. Fortinet is constantly increasing the number of applications that application control can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database and both of these databases have the same version number.

To view the version of the application control database installed on your FortiGate unit, go to the **License Information** dashboard widget and find the **IPS Definitions** version.

To see the complete list of applications supported by FortiGuard Application Control go to the FortiGuard Application Control List. This web page lists all of the supported applications. You can select any application name to see details about the application.

Application Control Actions

Allow

This action allows the targeted traffic to continue on through the FortiGate unit.

Monitor

This action allows the targeted traffic to continue on through the FortiGate unit but logs the traffic for analysis.

Block

This action prevents all traffic from reaching the application and logs all occurrences.

Reset

This action resets the session or connection between the FortiGate and the initiating node.

Traffic Shaping

This action presents a number of default traffic shaping options:

- guarantee-100kbps
- high-priority
- low-priority
- medium-priority
- shared-1M-pipe

View Signatures

This option brings up a window that displays a list of the signatures with the following columns:

- Application Name
- Category

- Technology - Technology is broken down into 3 technology models as well as the more basic Network-Protocol which would can be used as a catch all for anything not covered by the more narrowly defined technologies of:
  - Browser-Based
  - Client-Server
  - Peer -to-Peer
- Popularity - Popularity is broken down into 5 levels of popularity represented by stars. 5 stars representing the most popular applications and 1 star representing applications that are the least popular.
- Risk - The Risk property does not indicate the level of risk but the type of impact that is likely to occur by allowing the traffic from that application to occur. The Risk list is broken down into the following

Application considerations

Some applications behave differently from most others. You should be aware of these differences before using application control to regulate their use.

IM applications

The Application Control function for a number of IM application is not in the Web Based Manager, in the CLI of the FortiGate unit. These applications are:

- AIM
- ICQ
- MSN
- Yahoo

These applications are controlled by either permitting or denying the users from logging in to the service. Individual IM accounts are configured as to whether or not they are permitted and then there is a global policy for how to action unknown users, by the application, and whether to add the user to the black list or the white list.

The configuration details for these settings can be found in the CLI Reference guide under the heading of imp2p.

Skype

Based on the NAT firewall type, Skype takes advantage of several NAT firewall traversal methods, such as STUN (Simple Traversal of UDP through NAT), ICE (Interactive Connectivity Establishment) and TURN (Traversal Using Relay NAT), to make the connection.

The Skype client may try to log in with either UDP or TCP, on different ports, especially well-known service ports, such as HTTP (80) and HTTPS (443), because these ports are normally allowed in firewall settings. A client who has previously logged in successfully could start with the known good approach, then fall back on another approach if the known one fails.

The Skype client could also employ Connection Relay. This means if a reachable host is already connected to the Skype network, other clients can connect through this host. This makes any connected host not only a client but also a relay server.

SPDY

SPDY (pronounced speedy, it's a trademarked name not an acronym) is a networking protocol developed to increase the speed and security of HTML traffic. It was developed primarily by Google. The Application Control engine recognises this protocol and its required SSL/TLS component within Application Control sensors. It is counted as part of application traffic for Google and other sources that use the protocol.

Working with other FortiOS components

Application Control is not just a modulal that is inserted in to the OS and works independantly of all of the other components.

WAN Optimization

There is a feature that enables both IPS and Application Control on both non-HTTP WANOpt traffic and HTTP-tunneled traffic through HTTP CONNECT. The basic idea is that it hooks a scan connection to a port so that traffic will be redirected to the IPS engine before forwarding to a different module.

Application traffic shaping

You can apply traffic shaping for application list entries you configure to pass. Traffic shaping enables you to limit or guarantee the bandwidth available to the application or applications specified in an application list entry. You can also prioritize traffic by using traffic shaping.

You can create or edit traffic shapers by going to **Policy & Objects > Objects > Traffic Shapers**.

Direction of traffic shaping

When Traffic Shaping is enabled the direction that traffic shaping will be applied must also be chosen.

Forward direction traffic shaping refers to the direction of the initial connection. This would be the direction described by the policy that the Application Control Sensor is assigned to. If the policy has an Incoming Interface of LAN and an Outgoing Interface of wan1 then any Forward Direction Traffic Shaping profile will apply to network traffic heading in that direction only. If the connection used by that policy involved a response that included a download of Gigabytes of traffic the shaper would not be applied to that traffic.

Reverse Direction Traffic Shaping is applied to traffic that is flowing in the opposite direction indicated by the direction of the policy. If the policy has an Incoming Interface of LAN and an Outgoing Interface of wan1 then the shaper would only be applied to the traffic that was coming from the wan1 interface to the LAN interface.

For example, if you find that your network bandwidth is being overwhelmed by streaming HTTP video, one solution is to limit the bandwidth by applying a traffic shaper to an application control entry that allows the HTTP.Video application. Your users access the Web using a security policy that allows HTTP traffic from the internal interface to the external interface. Firewall policies are required to initiate communication so even though web sites respond to requests, a policy to allow traffic from the external interface to the internal interface is not required for your users to access the Web. The internal to external policy allows them to open communication sessions to web servers, and the external servers can reply using the existing session.

If you enable **Traffic Shaping** and select the Forward Direction shaper in an application sensor specified in the security policy, the problem will continue. The reason is the shaper you select for **Traffic Shaping** is applied only to the application traffic moving in the direction stated in the security policy. In this case, that is from the internal interface to the external interface. The security policy allows the user to visit the web site and start the video, but the video itself is streamed from the server to the user, or from the external interface to the internal interface. This is the reverse of the direction specified in the security policy. To solve the problem, you must enable **Reverse Direction Traffic Shaping** and select the appropriate shaper.

Shaper re-use

Shapers are created independently of firewall policies and application sensors so you are free to reuse the same shapers in multiple list entries and policies. Shared shapers can be configured to apply separately to each security

policy or across all policies. This means that if a shaper is configured to guaranteed 1000 KB/s bandwidth, each security policy using the shaper will have its own 1000 KB/s reserved, or all of the policies using the shaper will share a pool if 1000 KB/s, depending on how it is configured.

The same thing happens when a shaper is used in application sensors. If an application sensor using a shaper is applied to two separate policies, how the bandwidth is limited or guaranteed depends on whether the shaper is set to apply separately to each policy or across all policies. In fact, if a shaper is applied directly to one security policy, and it is also included in an application sensor that is applied to another security policy, the same issue occurs. How the bandwidth is limited or guaranteed depends on the shaper configuration.

If a shaper is used more than once within a single application sensor, all of the applications using the shaper are restricted to the maximum bandwidth or share the same guaranteed bandwidth.

For example, you want to limit the bandwidth used by Skype and Facebook chat to no more than 100 KB/s. Create a shaper, enable **Maximum Bandwidth**, and enter 100. Then create an application sensor with an entry for Skype and another entry for Facebook chat. Apply the shaper to each entry and select the application sensor in the security policy that allows your users to access both services.

This configuration uses the same shaper for each entry, so Skype **and** Facebook chat traffic are limited to no more than 100 KB/s in total. That is, traffic from both applications is added and the total is limited to 100 KB/s. If you want to limit Skype traffic to 100 KB/s and Facebook chat traffic to 100 KB/s, you must use separate shapers for each application control entry.

Application control monitor

The application monitor enables you to gain an insight into the applications generating traffic on your network. When monitor is enabled in an application sensor entry and the list is selected in a security policy, all the detected traffic required to populate the selected charts is logged to the SQL database on the FortiGate unit hard drive. The charts are available for display in the executive summary section of the log and report menu.

Because the application monitor relies on a SQL database, the feature is available only on FortiGate units with an internal hard drive.

While the monitor charts are similar to the top application usage dashboard widget, it offers several advantages. The widget data is stored in memory so when you restart the FortiGate unit, the data is cleared. Application monitor data is stored on the hard drive and restarting the system does not affect old monitor data.

Application monitor allows you to choose to compile data for any or all of three charts: top ten applications by bandwidth use, top ten media users by bandwidth, and top ten P2P users by bandwidth. Further, there is a chart of each type for the traffic handled by each security policy with application monitor enabled. The top application usage dashboard widget shows only the bandwidth used by the top applications since the last system restart.

Enable application control

Application control examines your network traffic for traffic generated by the applications you want it to control.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an application sensor.
2. Configure the sensor to include the signatures for the application traffic you want the FortiGate unit to detect.
3. Enable any other applicable options.
4. Enable application control in a security policy and select the application sensor.

Creating an application sensor

You need to create an application sensor before you can enable application control.

To create an application sensor

1. Go to **Security Profiles > Application Control.**
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter the name of the new application sensor.
4. Optionally, you may also enter a comment.

Adding applications to an application sensor

Once you have created an application sensor, you need to need to define the applications that you want to control. You can add applications using categories and/or application overrides. Categories will allow you to choose groups of signatures based on a category type. Application overrides allow you to choose individual applications.

To add a category of signatures to the sensor.

1. Go to **Security Profiles > Application Control**.
2. In the Category section, you can select 0 or more of the following categories.
   - Botnet
   - Business
   - Cloud.IT
   - Collaboration
   - Email
   - Game
   - General.Interest
   - IM
   - Network.Service
   - P2P
   - Proxy
   - Remote.Access
   - Social.Media
   - Storage.Backup
   - Update
   - Video/Audio
   - VoIP
   - Industrial
   - Web.Others

- All Other Known Applications
- All Other Unknown Applications
  When selecting the category that you intend to work with, left click on the category name to produce a drop down menu that includes:

- Allow
- Monitor
- Block
- Reset
- Traffic Shaping
- View Signatures

3. If you wish to add individual applications, use the Application Overrides widget.
   a. Select the **Add Signatures** icon
   b. Use the Search field to narrow down the list of possible signatures.
   c. Select the Use Selected Signatures.
4. Select, if applicable from the following options:
   - Deep Inspection of Cloud Applications
   - Allow and Log DNS Traffic
   - Replacement Messages for HTTP-based Applications
5. Select Apply

Creating a New Custom Application Signature

If you have to deal with an application that is not already in the **Application List** you have the option to create a new one.

1. Go to **Security Profiles > Application Control**.
2. Select the link in the upper right corner, **[View Application Signatures]**
3. Select the **Create New** icon
4. Give the new signature a name (no spaces) in the **Name** field.
5. Enter a brief description in the **Comments** field
6. Enter the text for the signature in the signature field. Use the rules found in the Custom IPS signature chapter to determine syntax.
7. Select **OK.**

Enabling application traffic shaping

Enabling traffic shaping in an application sensor involves selecting the required shaper. You can create or edit shapers in **Policy & Objects > Objects > Traffic Shapers**.

To enable traffic shaping

1. Go to **Security Profiles > Application Control.**
2. Select application signature(s) or category(s) from the Application Control sensor.
   a. If a category is selected, left click on the category. Select Traffic Shaping. Select the desired Traffic Shaper.
3. Select **Apply**.

Any security policy with this application sensor selected will shape application traffic according to the applications specified in the list entry and the shaper configuration.

Messages in response to blocked applications

Once an Application Control sensor has been configured to block a specified application and applied to a policy it would seem inevitable that at some point an application will end up getting blocked, even if it is only to test the functionality of the control. When this happens, the sensor can be set to either display a message to offending user or to just block without any notification. The default setting is to display a message. Setting this up is done in the CLI.

```
config application list
   edit <name of the sensor>
      set app-replacemsg {enable | disable}
   end
```

Application control examples

To help give a better understanding of how to implement Application Control and to give some ideas as to why it would be used, a number of examples of scenarios are included.

Blocking all instant messaging

Instant messaging use is not permitted at the Example Corporation. Application control helps enforce this policy.

First you will create an application sensor with a single entry that includes all instant messaging applications. You will set the list action to block.

To create the application sensor

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `no_IM` for the application sensor name.
4. Left-click on the **IM** category.
5. From the dropdown select **Block**.
6. Select **OK** to save the new sensor.

Next you will assign the sensor to a policy.

To enable application control and select the application sensor

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select the security policy that allows the network users to access the Internet and choose **Edit**.
3. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
4. In the drop down menu field next to the **Application Control** select the **no_IM** application sensor.
5. Select **OK**.

No IM use will be allowed by the security policy. If other firewall policies handle traffic that users could use for IM, enable application control with the **no IM** application sensor for those as well.

Allowing only software updates

Some departments at Example Corporation do not require access to the Internet to perform their duties. Management therefore decided to block their Internet access. Software updates quickly became an issue because automatic updates will not function without Internet access and manual application of updates is time-consuming.

The solution is configuring application control to allow only automatic software updates to access the Internet.

To create an application sensor — web-based manager

1. Go to **Security Profiles > Application Control**.
2. Select the **Create New** icon in the title bar of the **Edit Application Sensor** window.
3. In the **Name** field, enter `Updates_Only` as the application sensor name.
4. Using the left-click and drop down on the items in the **Category** list…
   a. Select **Monitor** from the dropdown menu.
   b. Select **Block** for the rest of the categories.
5. Select **OK**.

To create an application sensor — CLI

```
config application list
   edit Updates_Only
      config entries
         edit 1
            set category 17
            set action pass
         end
      set other-application-action block
      set unknown-application-action block
   end
```

You will notice that there are some differences in the naming convention between the Web Based Interface and the CLI. For instance the **Action** in the CLI is "`pass`" and the **Action** in the Web Based Manager is "**Monitor".**

Selecting the application sensor in a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — web-based manager

1. Go to **Policy & Objects > Policy > IPv4**.
2. Select a policy.
3. Select the **Edit** icon.
4. Under the heading **Security Profiles** toggle the button next to **Application Control** to turn it on.
5. In the drop down menu field next to the **Application Control** select the `Updates_only` list.
6. Select **OK**.

To select the application sensor in a security policy — CLI

```
config firewall policy
   edit 1
      set utm-status enable
      set profile-protocol-options default
      set application-list Updates_Only
   end
```

Traffic handled by the security policy you modified will be scanned for application traffic. Software updates are permitted and all other application traffic is blocked.

Intrusion protection

The FortiGate Intrusion Protection system combines signature detection and prevention with low latency and excellent reliability. With intrusion protection, you can create multiple IPS sensors, each containing a complete configuration based on signatures. Then, you can apply any IPS sensor to any security policy.

This section describes how to configure the FortiGate Intrusion Protection settings.

If you enable virtual domains (VDOMs) on the FortiGate unit, intrusion protection is configured separately for each virtual domain.

The following topics are included:

- IPS concepts
- Enable IPS scanning
- Configure IPS options
- Enable IPS packet logging
- IPS examples

IPS concepts

The FortiGate intrusion protection system protects your network from outside attacks. Your FortiGate unit has two techniques to deal with these attacks: anomaly- and signature-based defense.

Anomaly-based defense

Anomaly-based defense is used when network traffic itself is used as a weapon. A host can be flooded with far more traffic than it can handle, making the host inaccessible. The most common example is the denial of service (DoS) attack, in which an attacker directs a large number of computers to attempt normal access of the target system. If enough access attempts are made, the target is overwhelmed and unable to service genuine users. The attacker does not gain access to the target system, but it is not accessible to anyone else.

The FortiGate DoS feature will block traffic above a certain threshold from the attacker and allow connections from other legitimate users. The DoS policy configuration information can be found in the Firewall Handbook.

Signature-based defense

Signature-based defense is used against known attacks or vulnerability exploits. These often involve an attacker attempting to gain access to your network. The attacker must communicate with the host in an attempt to gain access and this communication will include particular commands or sequences of commands and variables. The IPS signatures include these command sequences, allowing the FortiGate unit to detect and stop the attack.

Signatures

IPS signatures are the basis of signature-based intrusion protection. Every attack can be reduced to a particular string of commands or a sequence of commands and variables. Signatures include this information so your FortiGate unit knows what to look for in network traffic.

Signatures also include characteristics about the attack they describe. These characteristics include the network protocol in which the attack will appear, the vulnerable operating system, and the vulnerable application.

To view the complete list of signatures, go to **Security Profiles > Intrusion Protection > IPS Signatures**. This will include the predefined signatures and any custom signatures that you may have created.

Protocol decoders

Before examining network traffic for attacks, the IPS engine uses protocol decoders to identify each protocol appearing in the traffic. Attacks are protocol-specific, so your FortiGate unit conserves resources by looking for attacks only in the protocols used to transmit them. For example, the FortiGate unit will only examine HTTP traffic for the presence of a signature describing an HTTP attack.

IPS engine

Once the protocol decoders separate the network traffic by protocol, the IPS engine examines the network traffic for the attack signatures.

IPS sensors

The IPS engine does not examine network traffic for all signatures, however. You must first create an IPS sensor and specify which signatures are included. Add signatures to sensors individually using signature entries, or in groups using IPS filters.

To view the IPS sensors, go to **Security Profiles > Intrusion Protection > IPS Sensor**.

IPS filters

IPS sensors contain one or more IPS filters. A filter is a collection of signature attributes that you specify. The signatures that have all of the attributes specified in a filter are included in the IPS filter.

For example, if your FortiGate unit protects a Linux server running the Apache web server software, you could create a new filter to protect it. By setting **OS** to **Linux**, and **Application** to **Apache,** the filter will include only the signatures that apply to both Linux and Apache. If you wanted to scan for all the Linux signatures and all the Apache signatures, you would create two filters, one for each.

To view the filters in an IPS sensor, go to **Security Profiles > Intrusion Protection > IPS Sensor**, select the IPS sensor containing the filters you want to view, and choose **Edit**.

Custom/predefined signature entries

Signature entries allow you to add an individual custom or predefined IPS signature. If you need only one signature, adding a signature entry to an IPS sensor is the easiest way. Signature entries are also the only way to include custom signatures in an IPS sensor.

Another use for signature entries are to change the settings of individual signatures that are already included in a filter within the same IPS sensor. Add a signature entry with the required settings above the filter, and the signature entry will take priority.

Policies

To use an IPS sensor, you must select it in a security policy or an interface policy. An IPS sensor that it not selected in a policy will have no effect on network traffic.

IPS is most often configured as part of a security policy. Unless stated otherwise, discussion of IPS sensor use will be in regards to firewall policies in this document.

Enable IPS scanning

Enabling IPS scanning involves two separate parts of the FortiGate unit:

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day. Firewall policies can also be used to deny traffic, but those policies do not apply to IPS scanning.
- The IPS sensor contains filters, signature entries, or both. These specify which signatures are included in the IPS sensor.

When IPS is enabled, an IPS sensor is selected in a security policy, and all network traffic matching the policy will be checked for the signatures in the IPS sensor.

General configuration steps

For best results in configuring IPS scanning, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an IPS sensor.
2. Add signatures and /or filters.
   These can be:
   - Pattern based
   - Rate based
   - Customized
3. Select a security policy or create a new one.
4. In the security policy, turn on **IPS**, and choose the IPS sensor from the list.

All the network traffic controlled by this security policy will be processed according to the settings in the policy. These settings include the IPS sensor you specify in the policy.

Creating an IPS sensor
